TO OUR READERS.

— x —

IN vain have we tried to compose something new for this our periodical address; we must therefore hope that you will accept our thanks for your continued and increased encouragement. It enables us to go on cheerfully and with renewed resolution to use our best powers, and to spare no outlay for obtaining the earliest and most reliable information relative to our legitimate subjects. "When I have endeavoured to be successful I am contented," were the words of a modern statesman, and as we think he was correct we venture to adopt those words and to feel as he does.

THE EDITORS.

FEB 17 1913

INDEX.

to the
Volume

- ABERDEEN, BON-ACCORD BIRD SHOW, 40;** Horticultural Society, 300
- Aberdeenshire,** weather in, 284
- Abutilons, ornamental,** 168
- Acothanthus spectabilis,** 375
- Aconitum,** 38
- Adelaide Botanic Garden Catalogue,** 411
- Adiantum palmatum,** 31
- Adulterations, detection of,** 291
- Agrides, descriptions of,** 430; various, 484
- Aeschynanthus,** in pots, 260; splendens, 48
- Agricultural Show, proposed international in London,** 215, 291
- Alexandra Palace, Bird Show, 118, 178;** Rose Show, 222, 481, 488
- Alan, Mr. J. P.,** 134
- Almond trees,** 222
- Alströméria chilensis,** 413
- Alternanthera green,** 116
- Alyssum Wierzbickii,** and culture, 464
- Amaryllises, culture,** 189, 477; a plea for, 374; repotting, 441; seedling, 413; watering, 389
- American blight,** 63
- American, harvest prospects,** 439; corn crop, 475; exports to England, 99
- Amaryllis, prizes for,** 260
- Amateur, 186, 288;** defined, 281
- Anaplois lacerata,** 72
- Annual flower management,** 261
- Annals, sowing hardy and half-hardy,** 267, 287; and their culture, 319; distasteful to slugs, 348; at Regent's Park, 461
- Anthurium, Andreanum,** 37, 86; tricolor, 71
- Antirrhinums, preservation of,** 45
- Ants, 247; r. aphides,** 181, 112, 323; banishing, 231, 343; in greenhouse, 55; preserving aphides, 219
- Aphis, destroying,** 397, on Peach trees, 382
- Aponogeton distachyon** from seed, 363
- Apple, notes on,** 84; tree ornamental, 65; grafting old, 75; blooming season, 5; trees in pleasure ground, 6; trees cankered, 130; tree grub, 389; trees unfruitful, 399
- Apples, winter, 17;** for orchards, 27; for market, 29; market, Baiton Free-Bearer, 45; and Apple trees, 50; protecting, 218; Northern Spy, 280
- Aquatic plants,** 325
- Araucaria Cookii,** 209
- Araucarias, large,** 15, 34
- Arbutus, fruiting,** 95; Uncdo in Yorkshire, 37
- Arrangement of flower beds,** 45
- Artichoke culture,** 249
- Arum crinitum insectivorous,** 483
- Asparagus, beetle,** 108; culture, 217, 240, 261, 283, 294, 433; cutting, 340, 349, 363; forcing, 74; planting, 470; prizes for, 300, 423
- Azalea polata,** 270
- Auricula culture, National,** 163, 370
- Auriculas, 263, 318;** hardy, 75; woolly aphis, 83, 182; culture, 94; at Slough and Loxford, 316; culture, 304, 397, 321; showing, 333, 357, 373; forced, 338; Crystal Palace, 340; Manchester Show, 336, 360; propagation, 343; repotting, 322; drying, 363; Society's Show, 371; at Failsworth, 431; striped, 470
- Azalea Souvenir du Prince Albert,** 166
- Azaleas, culture,** 343, 435; in December, 3; after flowering, 392; at Fulham, 383; Ghent Excellence, 114; liquid manure for, 55; mollis, 212; propagating, 212; white for forcing, 212; unhealthy, 288
- BALSAM CULTURE,** 205, 400
- Bamboo, in Annam, "Commercial Plants,"** 223; not growing, 343
- Bantams, 347, 383;** varieties of, 420
- Bark of tree, removing,** 288
- Barley cultivation, 1, 4, 155, 174**
- Bast, 471**
- Bath and West of England Poultry Show, 196, 320, 384, 457;** Flower Show, 452, 467
- Bause, Mr. F.,** 108
- Beans, Broad, 111;** dwarf for small garden, 116; experiments with Scarlet Runners, 225
- Bedding-out, 324, 361;** stock for, 239
- Bedding plant arrangement, 339**
- Bedding plants, preparing,** 212
- Bee-keepers' Association Show, 492**
- Bees—keeping, past, present, and future, 23;** keeping in Kansas, removing hives, 42; warmth and ventilation, 60; size of bar-framed hive, feeding, dysentery, fallen comb, unting swarms, 80; mortality, 98; feeding, wintering, 99; Scotch Society, 119; bar-framed hives, 120; wintering, bar-frame hive, 140; chloroforming, wintering, ventilating, introduction of Ligurian, 150; "The Apary," weak hives, deserted hive, stings, 160; wintering, 176; Ligurian history, 177; sting remedy, apiary work, 178; wintering, 186; feeding, bar-framed hives, 197; mice in hive, 215; wintering, 216; Italian r. British, 235; spring overhauled, crooked combs, 236; in California, 253; Ligurian, swarming r. non-swarming, 254; bar-framed hive management, 273; swarming r. non-swarming, feeding, 274; Ligurian r. black, 281; notes on ancient writers, 292; in America, husbandry of, 311; natural death of, 312; dying, 329; husbandry of, 330; this season, for profit, 347, 348; transferring, 348; hives, swarming r. non-swarming, 367; feeding, 368, combs in hives, 368; bar-framed box r. straw hives, 385; ligurianising, 386; dividing, wintering, bar-frame hives, 404; management of, 421; bar-frame hives, cking of, east-out of hive, comb foundations, 422; unfavourable seasons, 439; early swarms, 439; feeding, 440; prospects, 440; tapping flowers, 458; seasons of 1877 and 1878, 458; and beans, 475; comb foundations, 475; hive chloroformed, 476; strengthening, 476; royal cells, 476; four swarms, 483; pasture for, 486
- Beet, culture,** 315; sowing, 305
- Benias, Fra-Belli, 15;** Moonlight, 69; Saundersii semperflorens, 166; tuberous-rooted, 101, 149, 391; cuttings, 269; cuttings of tuberous-rooted, 307
- Belladonna Lily planting,** 343
- Berberis Darw**
- Besleria Inura,** 71
- Biennial defined,** 436
- Biennial flowers, sowing,** 379
- Bignonia, insects on,** 136

From observations taken near London during forty-three years, the average day temperature of the week is 75.1°; and its night temperature 50.5°.

VINE INSECTS.

SOME kinds of insects attack the Vine at all times of the year, but there are others which only prey on it during the season it is in leaf. It is the latter class, which includes thrips and red spider, that are generally most injurious; but unless where there are some deficiencies in the requirements of the Vine or its management the workings of these and other insects may be confined to a very short season, if they cannot be prevented from appearing altogether.

It is generally about the end of June when the weather begins to get excessively hot and during the three following months that insects increase and do the most damage to the Vine. It is a matter next to impossible to keep Vines entirely free from some insect or other throughout the whole season, and it is but just to say that it is by no means always an indication of bad management when one sees a few insects on Vines; yet what every Vine-grower tries to do is first to keep his Vines entirely free from insects, and next to prevent them from spreading and increasing to any serious extent when they do appear.

To give a little assistance on the last-named undertaking these notes are written. No person need feel alarmed at seeing one or two leaves in their vineyard assuming a slightly fiery colour through red spider, or one here and there becoming grey with thrips, as this occurs in nine vineyards out of every ten; but this is the point—do not let them spread further, or much further, because when they get on to every leaf there is no chance of preventing them from doing serious injury. Where there are only two or three of the leaves affected now, more will be every day attacked in the hot summer weather, so no one can fail to see the necessity of beginning to check the pests at once if they have not done so already.

Red spider is the first to which attention should be paid. To amateurs who do not know much about what this insect is I may say it is very small, so small indeed that a dozen or two of them on the back of a Vine leaf can hardly be seen with the eye, but when there is a crowd of them they are observable running about; but as good a way as any of detecting their presence is by the colour of the leaf. When fresh green leaves become rusty in colour red spider is almost sure to be the cause of it, unless in exceptional instances, and one of the best things to do as soon as these red leaves are observed is to sponge them all over with water mixed with a quantity of Gishurst compound. I do not think it is necessary to say what quantity of this valuable compound should be mixed to the gallon of water. We never weigh or measure it, but always apply it in larger or smaller quantities according to the number of insects to be killed. When the insects are numerous it should be made very strong. This sponging may be repeated either on the same leaves or others if they are attacked. In bad cases the Vines may be syringed with the mixture altogether, but this must not be done after the fruit has com-

menced colouring, or the berries will become discoloured, and perhaps tainted in flavour. After colouring has begun, and when it is not safe to syringe, if the spider is still spreading, a quantity of sulphur should be mixed up in water and then put on the hot-water pipes like paint. The fumes emitted from this when the pipes are hot will greatly check the spider and not injure the Vines. This treatment applies to moderate cases. When the leaves are much devoured by spider all the ventilators of the house must be shut close the first evening after the sulphur has been put on the pipes, the fire set agoing until the temperature of the house is up to 85°, when it may be allowed to decline to the usual heat. When the heat is raised so high the fumes are very strong, and if it does not kill all the insects in one night none of them will survive a second dose.

Thrips may be checked by sponging at the same time as that is done for spider; but while the latter generally appears on the old leaves first, the former always select the young leaves and tender points of the shoots, consequently they are not so easily sponged off. Fumigating with tobacco paper, however, is certain death to them, and this is much the surest way of dealing with them. When the thrips are plentiful the fumigating should be done two or three nights in succession; this, however, while it will kill the insects, will not destroy eggs, consequently the fumigation must be repeated in about ten days: if this plan is persistently followed the pest may be abolished. The smoke should be so thick in the house that objects cannot be distinguished 3 yards off. When thrips are young they are quite white, when old black in colour, and at all times they are long and sharp. They eat holes in the leaves and the points out of the young shoots, which is a hindrance to the progress of the Vine.

Green fly sometimes appears on the points of young Vine shoots, but I never saw them do much harm to them. However, I have no doubt they would do harm if very numerous, but they are easily disposed of in the same way as the thrips.

Mealy bug is the most filthy Vine pest, and although it seldom checks the growth of the Vine it spreads over the fruit and amongst the berries, which makes them unsightly and often unuseable. Little can be done to remedy this in summer when the Vines are in leaf further than brushing off any which may be seen about the leaves or rods; but in winter the loose bark cannot be too carefully cleaned from the rods and about the spurs, and afterwards scour the Vines thoroughly with water heated to 105°; but as we may probably have something to say on this matter when the time comes to see to it, it may be left for the present, and as something of more importance just now I may say that keeping the Vines in a free-growing healthy state will do more towards keeping them clear of insects than all other remedies put together, and above everything let them have liberal supplies of water at the root in the hot weather which appears now to be setting in.

Never mind although the fruit is black, water the same as if it were green, and give plenty of air on fine days, which will both prevent the flavour from declining or the

berries from splitting, which I understand are the two supposed dangers that are said to occur when the Vines are watered with the fruit hanging ripe.—A KITCHEN GARDENER.

WINDOW GARDENING AND WINDOW PLANTS.

IN writing for window gardeners it is meet to commence with

WINDOWS.—They must either open outward, inward—be fixed on pulleys to move upward—or constantly closed. As to the last—flowers or no flowers, it is to be hoped that a window incapable of admitting pure air may soon be as difficult to find as the Dodo. If it is convenient to have your flowers always inside, as where there is no suitable window sill outside, then let your sashes be hinged on the outside and move outwards only, as it will save you all the trouble of moving your flower baskets, vases, or pots when you wish to admit fresh air. Such windows are sometimes made with a second hinge and turn in on the side walls, as in Spanish bow windows; but when this is objectionable for appearance or otherwise the sashes turn inwards, and you have not to disturb your hardy plants and boxes outside. For your own convenience and the health of your plants the most desirable sashes are those that move perpendicularly on pulleys up or down. With such you can regulate the amount of air you think desirable, if any, and if you are of opinion top air is alone desirable lower the top sash.

AIR-GIVING.—With sash windows, which are never so close that some air cannot have access, especially in summer when the timber contracts and when air is most desirable, there is not the same risk your plants will become drawn or shanky, as one sees in the windows of the poor cottiers whose sashes enjoy a perpetual repose. You see a few leaves and a consumptive-looking flower at the top of a long stalk, perhaps standing in a saucer of water that some female member of the family ever and anon keeps strictly replenished. The soil is sodden, as it should not, and the plant is sickly. No bright colour glows from either flower or leaf, no more than from the cheeks of the pale girl inmates; and the atmosphere, which should constantly change, never does except when a fire is lighted and a current produced up the chimney, which is often insufficient to move the carbonated, carbureted, or miasmataladen atmosphere, these gases being heavier than common air. Such a plant has been mismanaged in the potting, as shall be shown, but the absence of pure air shortly terminates its untoward existence. In one word, if your plants cannot have pure air, especially during the late spring, summer, and autumn months, you will never have clean, healthy, bushy plants to reward your efforts or encourage your attention, and you will find yourself engaged in a labour of love vainly. When a cold wind blows, from October, say, to March, and of late years much later, your sashes must be thrown open with care, and then only a few inches on the top; and not at all if the wind happens to be a dry nor'-easter, which dries and crisps most injuriously any soft herbaceous plant exposed to its withering influence.

WINDOW STRUCTURES.—*Plain Red Pots.*—These placed on a balcony or a window sill, and intended to successfully grow flowers or plants in, would require an immense amount of time and trouble—as much experience in watering, planting, and protecting as would suffice similarly to manage a greenhouse, if not more; and I hardly remember a single instance under such circumstances where complete success was achieved. In winter nothing grows in pots outside, on window sills, &c., except bulbs and very hardy plants; and in summer and autumn the young rootlets at the side of the pot are roasted and the plant irretrievably ruined. Plain red earthenware pots, even though they are scrubbed and kept clean (if covered with green slime or moss they are odious), are most undesirable plant receptacles alone, and are liable to the following and many other objections:—

- a They require constant watering, especially in summer; if not, the plant dies—except, perhaps, Sedums.
- b If placed in saucers of water, as one frequently observes, the soil, especially in the absence of sufficient drainage, becomes sodden, and the plant shortly terminates an unpleasant lingering existence.
- c In plant structures appearances are much consulted, and the appearance of scrubby red pots on a window ledge with roasted or sickly plants is not prepossessing or enticing.

2. *Window Boxes.*—The dimensions of the box must be

made to suit the window; and its depth to what you propose to grow and how. Many things, as showy scarlet Geraniums, dwarf Nasturtiums, hardy Fuchsias, Pelargoniums, and almost all hardy annuals, including Mignonette, &c., can be grown outside in a plain deal box, lined with zinc or not, and perforated for drainage purposes; the soil suitable and the plants dwarf. But the perfection of such an arrangement would be an ornamental or plain box painted and stencilled in front, protected by a sheet of glass, hermetically sealed with putty, &c., to protect the stencil and the colouring, and for effect. Instead of having the box full of soil I should use damp moss, and only put flowers coming into bloom into it. Such a box would be always gay; and with a proper shade, which is almost indispensable to exclude heavy cold rains, hot sun, and hoar frost or hail, while it could be removed to admit genial showers and the warm night dews, one can have a perpetual summer or spring, especially in large towns, where, if they do not choose to go to the trouble of growing their own succession plants, they can have what they desire at almost every street corner, or Covent Garden Market, &c. Instead of the moss with which I propose to retain moisture around the pots and save the trouble or danger of watering, perhaps with hard water too, one can use good loam or leaf mould; and between your pots you can grow creepers, as Clematis, Canary Creepers, Ipomœas, Convolvulus, &c.

I need not point out the advantage of taking up a flower pot and plant when its beauty has gone and putting another exactly in its place, without having to wait a day for succession blooming, without any inconvenience from change of soil or manure, or having to tax your patience in watching the future companion of your hours of ease and enjoyment. To do this with real satisfaction we should grow our own plants, and for this purpose a backyard, a frame, and a knowledge of culture and propagation, to which we shall immediately come, would be necessary. No lady or gentleman will feel their honour or prestige in the least diminished by tucking up their sleeves, and perhaps donning an apron or blouse specially made for the purpose, to set seeds, plant cuttings brought home from visiting, transplanting, watering, repotting, syringing, and plucking off dead flowers, with the hundred and one little attentions always to be noticed by a diligent and intelligent eye. This is pleasurable amusement, I do not call it work or labour.

3. *Wardian Cases.*—In connection with window structures these observations would be incomplete without noticing the various designs, *en passant*, of miniature window greenhouses. They are to be found very common among the wealthy in London squares and in front of Dublin drawing-rooms, but still much more so on the Continent—Paris, Brussels, &c. They are a combination of the greenhouse idea with the box plan already sketched out, and from the following description of M. Victor Pagnet would induce the lover of floriculture to see their use and beauty generally recognised and extended:—“In Brussels the balconies are turned into greenhouses and miniature stoves gay with the brightest and greenest foliage, and in Paris there are many contrivances in use by means of which the rarest and most beautiful plants are produced. Passifloras cling to columns in the upper floors, water plants start into blossom in tiny basins curiously contrived in solid brickwork, and limpid water flows down a miniature rockery, from whose crevices start up Ferns and Lycopodiums.” Such contrivances are not common in England or Ireland, though they can be had. As these suggestions are mainly intended for those with limited means I shall merely say as the main intention should be to maintain a moist atmosphere, and as glass is comparatively cheap, and the other requisites for such easily procured, any person with plans, that can be had for nothing, and with a distinct idea of what is required, can make one to suit his own fancy and to grow Ferns, miniature plants, &c.

PROPAGATION.—This I have already referred to, and shall summarise my remarks under two heads—raising plants from seed and from cuttings.

Seed may be started in pans made shallow, in boxes, in pots, &c., covered half the diameter of an individual seed as a rule, something more or less as you require rapid or slow growth, but never too deep. The pans or pots should have coarse material underneath, and finer over that, and in most cases should be covered or dusted with sifted soil, or better with silver sand. If seeds are started early—speaking generally, if the temperature is under 50°, as in the early spring and winter months—a moist frame with 6 or 12 inches at least of stable manure would be necessary, unless they can be started

inside by means of hot water heat applied underneath the pan and covered with a bellglass. There are various contrivances for this purpose, but for convenience of starting cuttings, &c., a frame or pit of some sort is much to be preferred. In a warm room in February, March, or April all hardy and half-hardy seeds can be started in a window, over a fireplace, or in a cupboard, provided you place over the seed pan, &c., a closely fitting sheet of glass to retain sufficient moisture for germination. The seedlings when started must be gradually removed to a cooler situation, and the sheet of glass at first tilted up, and then removed finally. The less waterings seedlings receive the better. A deluge of hard water from a large rose watering pot will be certain death to most softwooded or tender seedlings. Better a hundred times to wholly plunge your seed pan into a tub of rain water. I advisedly refrain from naming any particular seeds, as all are in some respects different, and wish these remarks to be considered general. Then the sooner the seedlings are transplanted the more robust they become.

Cuttings.—As a rule a cutting should be short, not more than 3 or 4 inches. Provided it contains organisable matter enough at the base of a leaf or joint to form spongioles or rootlets, the younger it is, the sooner you will have your young plant to greet you. For them a moist frame or a moist atmosphere, however procured, is most necessary. This prevents flagging, and perspiration and absorption go hand in hand. Expose the same tender shoot to hot sun or a dry atmosphere, and you have been to the trouble of getting it in vain. A side shoot last year's wood will bear rougher treatment. For instance, take such of a Fuchsia in July, and several months may elapse before an opening bud may greet your eye. Take a side shoot of the same plant in June, and start in silver or clean road sand, and loam, in a moist frame, and it will beat the former started several months before. Prevent the cuttings from feeling the effect of the removal from the parent plant as indicated, and success will smile on you in most cases. If you fail, why, be more careful and try again.—W. J. M., *Clonmel*.

(To be continued.)

THE NATIONAL ROSE SOCIETY'S SHOW, CRYSTAL PALACE.—JUNE 29TH.

A GRAND show of Roses, a meeting of rosarians from all parts of England, a most numerous company, and a great competition—all these familiar features again presented themselves with, if anything, increased force to our notice.

Judging in some of the classes and exhibiting in others, which occupied my time in the morning, it was with great difficulty that I made any notes, for the public were admitted long before the judging was over, and then such was the rush that taking notes was impossible. Owing to the heat of the weather and the close atmosphere of the hall none of the great nurserymen uncovered their blooms before they were positively obliged, so that it was only by frequent visits that one could find out the most salient points of their stands.

The great nurserymen showed very well in the class for seventy-two. The names of Messrs. Cranston's winning stand are appended, but I may mention that the blooms most conspicuous for their excellence were Exposition de Brie, a fine old variety, too often belied for his companion Ferdinand de Lesseps; Lælia, rarely seen in excellent form now; Général Jacqueminot, splendid; Duke of Connaught, Lord Macaulay, Marquise de Castellane, Mons. J. Y. Teas, Fisher Holmes, and the Tea Rose Souvenir d'Elise. With regard to this Rose, which was shown in a great number of stands, I can truthfully say that during the eight years I have attended Rose shows I have never seen anything approaching to this in beauty of form and in refinement of colour, while as to size I did not think my old favourite was capable of attaining to anything like it. Mr. Cant, who was second for seventy-two, had a splendid stand of Roses remarkable for their freshness, and here he had decidedly as much a pull over the Hereford grower as Mr. Cranston distanced him in size. His blooms of Reynolds Hole, Xavier Olibo, and Horace Vernet among the darks, Marie Cointet and Marie Finger among the lights, and his Teas La Boule d'Or and Devoniensis, were blooms which will linger in the memory of most rosarians for a long time and haunt my dreams. Mr. George Paul was not up to his old form by any means, but he showed some very fine blooms. Lord Macaulay, Jean Liabaud (well shown in several stands), Sultan of Zanzibar, were all good representatives of the darker shades of colour; while Rev. J. B. M. Amm, Marie Finger, Abel Grand, Emily Laxton, asserted the claims of the lighter Roses to our favour. Although not strong in Teas I had fine examples of Maréchal Niel, Alba Rosea, and Souvenir d'Elise. Mr. Keynes', or rather I should say Mr. Wyatt's stand, as conspicuous for its grand Teas. The Salisbury nursery was

always famous for this lovely class of flower, and Jean Ducher, Catherine Mermet, Niphotos, Souvenir d'Elise were certainly the cream of his collection. Mr. Mitchell also staged an even seventy-two with several grand Teas in it.

The class for forty-eight trebles was well represented also, and the Roses I think showed to much more advantage than in the preceding class. Messrs. Cranston were again first with splendid trebles of Mdle. Eugénie Verdier, Marquise de Mortemart, Le Havre, Xavier Olibo, Marie Baumann, Louis Van Houtte, Niphotos, and Castellane. Mr. Wyatt's (Messrs. Keynes') trebles, however, ran him very close, and at a cursory glance appeared almost finer. Reynolds Hole, Marie Baumann, Marie Cointet, Niphotos, Moiré, Duke of Wellington, Souvenir d'Elise, Triomphe de Rennes, and Catherine Mermet were among his best; Mr. Cant had also lovely trebles. His La France and La Boule d'Or were exceptionally good, and Souvenir d'Elise, Niphotos, Maréchal Niel also grand; while among the Hybrid Perpetuals he had splendid specimens of Horace Vernet, of which Rose he showed a superb box of twelve. How any judges could refrain from giving an extra first prize to this stand passes my belief, and will ever be a mystery to Mr. Cant. Marie Baumann shown by Mr. Curtis of Torquay was grand beyond expression, but Horace Vernet was equally so. Mr. Paul's forty-eight trebles contained among others good specimens of Comtesse de Serenye, a somewhat difficult Rose to show clean and well opened; Mrs. Baker (who was also present in the flesh, greatly rejoicing in her well-won triumph in carrying off the challenge cup); Horace Vernet, Duchesse de Morny, Catherine Mermet, Maréchal Niel, Marie Rady, Madame Lacharme, Mons. Noman, Madame Clert, and Sir Garnet Wolseley.

Such is the *résumé* of the chief classes in the Great Show by the earnest and accomplished rosarian "WYLD SAVAGE." It leaves little to be added beyond detailing the honours won at the long-anticipated contest, and enumerating the varieties which brought additional fame to their owners. Before, however, doing this, and as affording an idea of the magnitude of the Show, it may be stated that, despite all the predictions of failure, there were 457 entries from 132 exhibitors, comprising upwards of 12,000 Roses. A large number indeed fell out in the smaller classes, but there must have been upwards of 10,000 blooms staged at the Exhibition. Worthy of prominent mention, too, is a fact unprecedented in Rose shows, and tending to show how much importance was attached to the Exhibition—viz., that Mr. Jowitt, of The Old Weir, Hereford, and Mr. Cranston of King's Acre chartered a special train in order that they might cut their Roses fresher, leaving Hereford at eleven o'clock at night! Now to the classes.

NURSERYMEN.—In the great class of seventy-two varieties, single blooms, Messrs. Cranston & Co., King's Acre, Hereford, won the chief prize—a piece of plate and £5—with a collection of great weight, brilliancy, and freshness. The following were the varieties and their arrangement in the boxes, each row being read from left to right:—Back row: Mdle. Eugénie Verdier, Marie Baumann, Paul Neyron, Madame Lacharme, Duke of Edinburgh, Edouard Morren, Maurice Bernardin, Comtesse de Serenye, François Michelin, Le Havre, Madame Charles Wood, Baronne de Rothschild, Comtesse d'Oxford, Madame Nachury, Xavier Olibo, Mdle. Marie Finger, Madame Victor Verdier, Mons. Woolfield, Reynolds Hole, Annie Laxton, Etienne Levet, Madame Willermoz, Mdle. Marie Rady, and Duchesse de Vallombrosa. Middle row: Horace Vernet, Princess Beatrice, Général Jacqueminot, Auguste Rigotard, La France, Louis Van Houtte, Capitaine Christy, Nardy Freres, Lord Macaulay, Marguerite de St. Amand, Marquise de Castellane, Star of Waltham, Madame de Gibot, Belle Lyonnaise, Baron Hausmann, Clovis, Alice Dureau, Abel Carrière, Souvenir de Arthur Sansal, Duc de Montpensier, Duchess of Edinburgh, Madame Jacqueur, Victor Verdier, and Duke of Wellington. Front row: Marquise de Mortemart, Exposition de Brie, Lælia, Duke of Connaught, Mons. E. Tournier, Mons. Noman, Madame C. Crapelet, Mrs. Baker Duc de Morny, Maréchal Niel, Mons. E. Y. Teas, Niphotos M. Adèle de Murinais, Devienne Lamy, Souvenir de la Malmaison, Antoine Ducher, Sénateur Vaisse, and Madame Vidot. Mr. Cant, Colchester, was an excellent second, the blooms being wonderfully fresh, but generally smaller than those from King's Acre. Amongst the high-coloured varieties Xavier Olibo, Horace Vernet, Star of Waltham, Charles Lefebvre, Madame Marie Rady, Duc de Wellington, Pitard, and Duchesse de Caylus were remarkably rich and fine; and amongst the lights the following were prominent by their form, freshness, and purity:—Souvenir d'Elise, La France, Mdle. Marie Cointet, Niphotos, La Boule d'Or, and Devoniensis. Messrs. Paul & Son, Cheshunt, were a rather close third with blooms somewhat longer but a trifle dull, and some of them injured by either sun or wind. The best were Souvenir d'Elise, a Rose that was in splendid condition throughout the Show, Marie Baumann, Lord Macaulay, Etienne Levet, Niphotos, Capitaine Christy, Maréchal Niel, and Duchesse de Caylus. Messrs. Keynes & Co., Salisbury, won the fourth prize; the noteworthy blooms were Souvenir d'Elise, Horace Vernet, Etienne Levet, Catherine Mermet, François Michelin, Jean Ducher, splendid; and Fisher Holmes. The others were more or less injured by the weather. Messrs. Mitchell & Sons, Uckfield, were the remaining exhibitors.

In the class of forty-eight trebles six very fine collections were staged, and the Judges—Messrs. Hole, Peach, and Baker—were long in making their awards. Messrs. Cranston & Co. were again in the premier position with blooms the great majority of which combined great size with good form and high quality, only a very few being faulty. The varieties were Exposition de Brie, Lælia, Alice Dureau, Lord Macaulay, Madame C. Wood, Paul Neyron, Madame Hippolyte Jamin, Mrs. Baker, Annie Laxton, Duc de Morny, Horace Vernet, Mons. Noman, Marquise de Castellane, Madame Lacharme, Duchess of Edinburgh, Mdle. Marie Rady, Niphetos, Victor Verdier, Duchesse de Vallombrosa, Beauty of Waltham, Mons. Fillion, Mdle. Marie Cointet, Capitaine Christy, Mons. E. Y. Teas, Madame Eugénie Verdier, Reynolds Hole, Marie Baumann, Marquise de Mortemart, Edouard Morren, Fisher Holmes, Maréchal Niel, Xavier Olibo, La France, Le Havre, Maurice Bernardin, Baronne de Rothschild, Comtesse d'Oxford, Duc de Wellington, Louis Van Houtte, Princess Beatrice, Marguerite de St. Amand, Duke of Edinburgh, Madame C. Crapelet, Nardy Frères, Souvenir d'Arthur de Sansal, Comtesse de Serenye, Général Jacqueminot, and Mons. Woolfield. The remaining prizes were awarded to Messrs. J. Keynes & Co., G. Paul & Son, and Mr. Cant in the order of their names. The Salisbury collection was extremely fresh and beautiful, and only lost the first prize by a few points. The Cheshunt and Colchester blooms were also of generally excellent quality, and the competition throughout the class was exceedingly close.

Mr. C. Turner, Slough, won the premier prize in the class for thirty-six single blooms (in which nine collections were staged) with a remarkably good and very regular collection, consisting of Madame Ferdinand Jamin, Xavier Olibo, Paul Neyron, Madame Joséphine Guyet, Capitaine Christy, Horace Vernet, Edouard Morren, Devoniensis, Louis Van Houtte, Annie Laxton, Souvenir d'Elise, Marie Baumann, Mad. Thérèse Levét, Villaret de Joyeuse, La Rosière, Margaret Brassac, Maréchal Niel, Comtesse d'Oxford, Ville de Lyon, Charles Lefebvre, Madame Jules Margottin, Ferdinand de Lesseps, La France, Camille Bernardin, Mons. Noman, Beauty of Waltham, Marquise de Castellane, François Louvat, Mdle. Eugénie Verdier, Penelope Mayo (fine), Abel Grand, Star of Waltham, Le Havre, Niphetos, Madame George Paul, and Madame G. Huzard. Messrs. Curtis, Sandford & Co., Torquay, were a very close second. Splendid in this collection were Louis Van Houtte, Duc de Wellington, Horace Vernet, Avocat Duvivier, Monsieur E. Y. Teas, Star of Waltham, Madame Vidot, La France, Margaret Brassac, Etienne Levét, and Victor Verdier. Mr. G. Prince, Oxford, was placed third with rather small but charmingly fresh blooms. The following Teas in this collection were extremely fine and very beautiful—namely, Souvenir d'Elise Vardon, Alba Rosea, Marie Guillot, and Catherine Mermet. The fourth prize was awarded to Messrs. Kinmont & Kidd, Exotic Nursery, Canterbury, with a very good collection, containing the finest example of Reynolds Hole in the Show—indeed, one of the finest blooms that have ever been seen of this richly coloured but somewhat uncertain Rose.

Five collections were exhibited in the class for twenty-four trebles. Mr. Cant won first honours with blooms of very high quality La France, Charles Lefebvre, Souvenir d'Elise, Horace Vernet, Xavier Olibo (magnificent), Antoine Ducher (very fine), Reynolds Hole, Mons. Noman, Devoniensis, Marie Baumann, Ferdinand de Lesseps, Mdle. Marie Cointet, Baronne de Rothschild, Prince Arthur, La Boule d'Or (fine), Sénateur Vaisse, Ville de Lyon, Fisher Holmes, Mdle. Marie Rady, Elie Morel, Comtesse d'Oxford, Marguerite de St. Amand, and Duchesse de Vallombrosa. Messrs. Keynes & Co. were a very close second. Souvenir d'Elise and Triomphe de Rennes in this collection were marvellously fine, and very good were Niphetos, Catherine Mermet, and Etienne Levét. Messrs. Cranston & Co. were third with an admirable collection, and Messrs. G. Paul & Son fourth with blooms considerably weatherworn, and not by any means up to the usual high style of Cheshunt.

Thirteen collections were exhibited in the class of twenty-four single blooms, some of them being inferior, a few good, but none grand. Mr. C. Turner was clearly first with admirable boxes consisting of Paul Neyron, Horace Vernet, Victor Verdier, Louis Van Houtte, Capitaine Christy, Duke of Edinburgh, Elie Morel, Comtesse d'Oxford, Madame Thérèse Levét, Le Havre, Ville de Lyon, Fisher Holmes, Maréchal Niel, Beauty of Waltham, Souvenir d'Elise Vardon, Charles Lefebvre, Madame Huzard, good; Lord Macaulay, Marquise de Castellane, François Louvat, Star of Waltham, Margaret Brassac, very fine; Mons. Noman, and Penelope Mayo, excellent. Messrs. Curtis, Sandford, & Co. were placed second; Louis Van Houtte, Madame C. Wood, Etienne Levét, Madame C. Joigneaux, Le Havre, Hippolyte Jamin, and Général Jacqueminot were the cream of the collection. Third honours were awarded to Mr. H. Frettingham, Beeston Nursery, Nottingham; and fourth to Mr. George Prince, Oxford.

We now arrive at the last of the nurserymen's classes, and certainly one of the most beautiful—namely, the class for twelve varieties of Teas or Noisettes, single blooms. Messrs. Mitchell and Sons, Pitdown Nurseries, Uckfield, who usually exhibit Teas so splendidly, won the premier position with superb examples of

Devoniensis, Duc de Magenta, Madame Margottin, Souvenir d'Elise Vardon, grand; Maréchal Niel, Catherine Mermet, Madame Julie Mansais, Madame Céline Narey, Boidron, Souvenir d'un Ami, Louise de Savoie, and Niphetos. Mr. Cant was a good second with an excellent stand containing superior blooms of Caroline Kuster, Devoniensis, Maréchal Niel, Souvenir d'Elise, Catherine Mermet, Madame Willermoz, Boule d'Or, splendid; Marie Van Houtte, Rubens, and Souvenir de Paul Neyron. Third honours went to Messrs. G. Paul & Son, the gems of the stand being Comtesse de Nadaillac and Alba Rosea. Messrs. Turner, Prince, Piper, and Keynes all exhibited well in this excellent class.

AMATEURS.—The competition in many of the classes in this section of the Show was good, and Roses of superior quality were staged. The class in which the greatest interest was manifested was unquestionably the one of forty-eight single blooms wherein the splendid challenge cup, value fifty guineas, offered under such liberal conditions by Messrs. Cranston & Co., was the coveted prize. The cup, it will be remembered, was won last year by T. Jowitt, Esq., The Old Weir, Hereford, and if he had secured the first position in the class this year the trophy would have become his property; but although Mr. Jowitt staged a collection of remarkable merit and fully equal if not superior to his contribution of last year, yet his great rival, R. N. G. Baker, Esq., of Heavittree, was this year too powerful for his worthy antagonist and won the cup by a few points. So even were the collections that the Judges were a considerable time before they were able to arrive at a decision. Both collections were of superior merit, the blooms being singularly fresh and excellently set up, but Mr. Baker's were slightly the heavier and hence won the prize. The Heavittree collection consisted of the following varieties—Dr. Andry, Victor Verdier, Jean Liabaud, Edouard Morren, Mdle. Marie Rady, Louis Van Houtte, Centifolia Rosea, Marie Baumann, Devienne Lamy, Madame Charles Wood, Madame Berthe du Mesnil de Montchaucourt, Xavier Olibo, Marquise de Castellane, Comtesse d'Oxford, Baronne de Rothschild, Fisher Holmes, Camille Bernardin, Sir Garnet Wolseley, Abel Carrière, Madame Bravy, Mons. Noman, Charles Lefebvre, Mons. G. Tournier, Comtesse de Serenye, Ferdinand de Lesseps, Miss Hassard, Madame Caroline Kuster, Alfred Colomb, Marguerite de St. Amand, Mons. E. Y. Teas, Etienne Levét, Auguste Neumann, Sénateur Vaisse, François Michelon, Duke of Connaught, Marquise de Mortemart, Madame Prosper Langier, Duc de Wellington, Mdle. Eugénie Verdier, Madame Victor Verdier, Magna Charta, Auguste Rigotard, Royal Standard, Duchesse de Caylus, and Sultan of Zanzibar. Mr. Thos. Jowitt, who won the second prize of £9, staged Mdle. Marie Rady, La France, Général Jacqueminot, Mons. Noman, Duke of Edinburgh, Xavier Olibo, Capitaine Christy, Alfred Colomb, Charles Lefebvre, Madame Nachury, Duc de Wellington, Baron de Bonstetten, Madame Furtado, Marie Baumann, Marguerite de St. Amand, Horace Vernet, François Michelon, Madame Charles Crapelet, Comtesse de Serenye, Lord Herbert, Madame Marie Finger, Le Havre, Royal Standard, Prince Camille de Rohan, Beauty of Waltham, Alba Rosea, Reynolds Hole, Comtesse d'Oxford, Docteur Andry, Devoniensis, Paul Verdier, Abel Grand, Clotilde Roland, Belle Lyonnaise, Mons. E. Y. Teas, Mdle. Marie Cointet, Olivier Delhomme, Reine Blanche, Hippolyte Jamin, Triomphe de Rennes, Cheshunt Hybrid, Maréchal Niel, Jean Liabaud, and Marie Van Houtte. The Rev. Reynolds Hole, Causton Manor, Newark, was placed third with large and fine blooms; and Mr. W. Nichol, gardener to H. Powell, Esq., Drinkston Park, Bury St. Edmunds, fourth. There were seven competitors. According to the conditions the cup must now be won next year, and Mr. Baker and Mr. Jowitt can be the only competitors; a great Rose duel is therefore in store, and a keen contest will be anticipated.

In the class for thirty-six single trusses first honours fell to Mr. J. Brown, gardener to A. J. Waterlow, Esq., Great Doods, Reigate, who won with excellent examples of Miss Hassard, Souvenir de Paul Neyron, Emilie Hausburg, Jean Ducher, Xavier Olibo, Gloire de Dijon, Henri Ledechaux, Anna Olivier, Edouard Morren, Reynolds Hole, Souvenir d'un Ami, Alfred Colomb, Capitaine Christy, Lord Macaulay, Duchesse de Vallombrosa, Dr. Andry, Marie Van Houtte, Catherine Mermet, Sultan of Zanzibar, Alba Rosea, François Premier, Souvenir d'Elise, Beauty of Waltham, Impératrice Eugénie, Duke of Connaught, François Fontaine, Auguste Neumann, Jean Pernet, Star of Waltham, La France, Annie Wood, Madame Willermoz, Duc de Rohan, Louis Van Houtte, Niphetos, and Marie Rady. Mr. Baker was awarded the second prize, Mr. J. Lewin Curtis, Chatteris, Cambs, the third; and Mr. John Hollingworth, Turkey Court, Maidstone, the fourth.

Twenty-four collections were staged in the class for twenty-four varieties, single blooms, and the first prize—a piece of plate—was awarded to Mr. Henry Atkinson, Warley, Brentwood, who staged Beauty of Waltham, Victor Verdier, Marie Baumann, Marquise de Castellane, Docteur Andry, Mdle. Marguerite Dombrain, Duke of Edinburgh, Monsieur Noman, Antoine Ducher, Ville de Lyon, Lord Macaulay, Edouard Morren, Fisher Holmes, Baronne de Rothschild, Maurice Bernardin, Hippolyte Jamin, Duchesse de Vallombrosa, Duchesse de Morny, Comtesse d'Oxford, La France, Xavier Olibo, Mdle. Marie Cointet, Mdle. Marie Rady, and Henri Ledechaux. Mr. Jowitt was placed second; Mr. J.

Sargent, Reigate, third; Mr. J. H. Pemberton fourth; Mr. T. F. Burnaby Atkins, Halstead Place, Sevenoaks, fifth; and Mr. J. Edwards, Stisted Rectory, Braintree, Essex, sixth. A great class and a good one.

In the class for twelve Roses, distinct, three trusses of each, Mr. Baker was placed first with good examples of Marie Baumann, Fisher Holmes, Mdlle. Marie Rady, Xavier Olibo, Marquise de Castellane, Charles Lefebvre, Victor Verdier, Comtesse d'Oxford, Madame Caroline Kuster, Monsieur Noman, Edouard Morren, and Marguerite de St. Amand. Mr. John Hollingworth, Turkey Court, Maidstone, was awarded the second prize; and Mr. J. Ridout, gardener to T. B. Haywood, Esq., Woodhatch Lodge, Reigate, the third. Mr. John Quennell, Brentwood, being placed fourth. There were nine competitors in this class.

The class for twelve singles was a very strong one. Some splendid stands were staged, but none of them nearly equal to the box with which Mr. Smallbones won the cup last year. A. G. Soames, Esq., of Irnham Park, Bourne, Lincolnshire, was the recognised winner. His grand blooms were of Marie Van Houtte and Mons. Furtado, never before seen in such perfection. This difficult Rose to grow and show was here seen large in size and of Centifolia form, each petal wrapping round his neighbour in the very centre like a fine bloom of Madame Bravy. Captain Christy's stand was so good that the Judges could not do otherwise than give him an equal first. Mr. John Pearce, gardener to Professor Adams, Cambridge, carried off the second honours, and Mr. Joseph Lakin of Chipping Norton third. Rev. Alan Cheales, Brockham Vicarage, Surrey, was fourth with a very pretty stand; Mr. A. Evans of Marston fifth, and Mr. J. Wakeley of Rainham sixth.

The class for six Roses, distinct, was also hotly contested. Capt. Christy, Buckhurst Lodge, Westerham, again won the first prize. Mr. Joseph Lakin turned the tables on Mr. Soames, who were second and third, and Rev. Alan Cheales whipped in with a lovely lot, which but for one small bloom of Victor Verdier would have taken a much higher place.

The class for six suburban-grown Roses—that is, Roses grown within eight miles from Charing Cross—would have been a failure had not Mr. Scott, South Wimbledon, staged such an admirable half-dozen. Mr. Batchelor, gardener to A. Druce, Esq., Dulwich Common, was placed second; and Mr. John Bateman, 1, Prospect Terrace, Upper Holloway, third. The fourth prize was withheld.

For twelve Teas or Noisettes, distinct, single trusses, there were eighteen competitors. The first prize was awarded to Mr. J. Brown, gardener to A. J. Waterlow, Esq., Great Doods, Reigate, for an exquisite collection consisting of Catherine Mermet, Jean Ducher, Louise de Savoie, Devoniensis, Madame Berard, fine; Madame Willermoz, Madame Camille, Caroline Kuster, Amazon, Souvenir d'Elise, Jean Pernet, and Alba Rosea. Mr. W. Smith, gardener to Mrs. Round, Birch Hall, Colchester, was placed second; Mr. W. Nichol third; and Mr. John Pearce, gardener to Professor Adams, fourth. A charming class, and much admired. In the class for eighteen Teas or Noisettes, six varieties, three trusses of each, Mr. John Hollingworth, won first honours with Souvenir d'Elise Vardon, Marechal Niel, Madame Willermoz, Cheshunt Hybrid, Madame Margottin, and Souvenir d'un Ami. The Rev. J. B. M. Camm received the second prize, the stand containing good examples of Souvenir de Paul Neyron, Madame Margottin, Madame Bravy, and Devoniensis.

OPEN CLASSES.—In the class for twelve new Roses which must not have been in commerce previous to 1875, Messrs. Paul and Son were awarded the first prize with a very excellent stand, comprising Mdlle. Marie Pernet, a large and full Rose; Duchesse de Vallombrosa, Sultan of Zanzibar, Rev. J. B. M. Camm, Jean Souperet, a very dark and velvety satin Rose with a cupped centre and the outer petals reflexed; Emily Laxton, Duke of Connaught, Marchioness of Exeter, Star of Waltham, Madame Pernet, Mrs. Laxton, and Magna Charta. Mr. Charles Turner was placed second, exhibiting Richard Laxton, Oxonian, Margaret Brassac, Royal Standard, Duke of Connaught, Rev. J. B. M. Camm, Henry Bennet, Penelope Mayo, a Rose of first-class merit; John Stuart Mill, Duchesse de Vallombrosa, Madame Deveret, and Prince Arthur. Messrs. Curtis, Sandford, & Co., Devon Rosery, Torquay, were awarded the third prize. For twelve blooms of Etienne Levet, Messrs. Paul & Son, The Old Nurseries, Cheshunt, won the premier position with remarkably fresh blooms; Messrs. Keynes & Co., Salisbury, being placed second with larger examples but slightly faded. The third prize was withheld, as it was also in the three following classes. For twelve blooms of Francois Michelon Messrs. Keynes & Co., Salisbury, were placed first with rather small blooms; and Mr. George Cooling, nurseryman, Bath, second with overblown examples. For twelve blooms of Jean Liabaud the first prize was awarded to Messrs. Cranston & Co. for blooms intensely rich, velvety, and fine; Messrs. Paul & Sons, Cheshunt, having the second prize. For single blooms of Marechal Niel, Mr. Charles Turner, The Royal Nurseries, Slough, won the chief position with splendidly coloured blooms; Mr. George Cooling, nurseryman, Bath, having the second prize. For twelve blooms of Marguerite de St. Amand Messrs. Paul & Son, The Old Nurseries, Cheshunt, were placed first with remarkably fresh and fine

examples; and Messrs. Keynes & Co., Salisbury, second. For twelve blooms of any Hybrid Perpetual not named above, dark, thirteen excellent collections were staged. Messrs. Curtis, Sandford, & Co., Devon Rosery, Torquay, won first honours with faultless blooms of Marie Baumann. Mr. B. R. Cant, Colchester, was placed second with magnificent examples of Horace Vernet; Messrs. John Laing & Co., Stanstead Park, Forest Hill, having the third prize with Marie Baumann. For twelve single trusses of any Hybrid Perpetual not named above, light, the first prize was awarded to Messrs. Paul & Son, Cheshunt, for large and remarkably fine examples of Capitaine Christy. Mr. J. Ridout, gardener to J. B. Haywood, Esq., Wood Hatch Lodge, Reigate, was placed second with Baronne de Rothschild, splendid; and Messrs. Cranston & Co., third with Madame Lacharme, very fine. For twelve single trusses of any Tea or Noisette not named above Mr. B. R. Cant won first honours with magnificent examples of La Boule d'Or; Messrs. Keynes & Co. were second with Souvenir d'Elise, fine; and Mr. George Prince, 14, Market Street, Oxford, third with Jean Ducher. For three trusses of any new seedling Rose the first prize was awarded to Messrs. W. Paul & Son, Nurseries, Waltham Cross, N., for Duchess of Bedford, a fine Rose of the Beauty of Waltham type but richer in colour; Messrs. Paul & Son, Cheshunt, having the second place with a fine variety raised by Capt. Christy and named Earl of Beaconsfield. It has the form of Marie Baumann with the colour of Comtesse d'Oxford. For the best collection of "Old Roses" (any Roses in commerce prior to 1840), Mr. Julius Sladden, Chipping Norton, was the only exhibitor, and won the prize with a very interesting collection consisting of about fifty varieties. They were exhibited in large bunches and were rather too crowded to display them to the greatest advantage. They were much admired. A prize was offered for the best exhibition stand other than those in ordinary use, and covered with material other than moss, which was won by Mr. E. R. Whitwell, Barton Hall, near Darlington. The box was similar to an ordinary Rose box, but had a neat beading round its inner edge, half an inch below which was a black velvet-covered lid or platform, in which the tubes were inserted. An extra prize was awarded to the Rev. Alan Cheales for a box very similar, but the velvet-covered top was an inch or more lower than the edges of the box.

MISCELLANEOUS.—Messrs. Wm. Paul & Son were awarded an extra prize for an extensive, varied, and excellent collection of twenty boxes of cut Roses. Mr. W. Runsey, Joyning's Nursery, Waltham Cross; Mr. Mayo, Oxford; and Messrs. Cutbush and Sons, Highgate, exhibited admirable stands of Hybrid Perpetuals, and Mr. Corp. Oxford, an extensive and charming collection of Tea Roses shown in bunches in the bud state.

The Show was a great Show undoubtedly, and as good as it was great, but it was not arranged to the best advantage. Some portions of the tables were much overcrowded, there being no division whatever between many of the competing collections, while in other parts of the tables were large blanks which marred considerably the effect of the Exhibition. The arrangements, too, for the admission of the representatives of the press were the most faulty the reporters ever experienced, and their difficulty in obtaining access to the Palace was such as they never met with before at any horticultural exhibition.

STRAWBERRY GROWING.

HEREWITH I forward samples of Strawberry plants grown at Weaverthorpe on light gravelly soil with chalk rock for a subsoil. I wish to call special attention to the plant marked No. 1 (Preston Seedling) as illustrating what a grand crop of fruit it is possible to grow on one-year-old plants. Last year at this time the land was growing a crop of Potatoes; during July the Potatoes were taken up and the ground dug over, manured, and planted with Strawberry runners. Some little while since when I stated I had produced 1 lb. of fruit per plant on one-year-old plants the statement seemed to take some by surprise. The others are two-year-old plants of well-known varieties full of leaf and full of fruit—how much I will not dare say.

With an unlimited demand for ripe fruit there need be little doubt as to the profitability of Strawberry growing. Planted in August after a fallow crop such as Potatoes, in rows 36 by 18 inches apart, and estimating each plant to produce 8 ozs. of fruit each season, we may realise a gross money value equal to £100 per acre, a sum amply sufficient to cover all expenses of cultivation and still leave a handsome profit for the cultivator. Plums and Apples have to be planted years before they will yield a crop. Not so with the Strawberry. If good varieties be selected and planted early in August, followed up with liberal cultivation, a crop of fruit will reward the cultivator though all other fruit crops fail. To tend the plants with "loving care," not leaving all to the "hired man," to keep the hoe constantly at work so that the soil never has a chance

to become crusted over or a weed to get beyond its seed leaf, are golden rules for the amateur to follow.—W. LOVEL.

[The plants sent us by Mr. Lovel are marvellously well grown, and heavily laden with masses of fruit. As regards productiveness Preston Seedling, to which Mr. Lovel alludes, Eclipse, and Vicomtesse Héricart de Thury, or, as it is sometimes called, Garibaldi, are especially noteworthy.—EDS. J. OF H.]

LEEDS HORTICULTURAL SHOW.

JUNE 26TH, 27TH, AND 28TH.

SIMILARLY to the great Yorkshire gala referred to last week, and at which horticulture is the primary feature, the annual flower Show held in the large, wealthy, and important town of Leeds is made the leading feature of a great fête comprising other attractions not incompatible with the central object of the promoters of the Show.

The display was held as usual in the Horticultural Gardens, which are situated in the suburbs of the town and at an altitude considerably above its level, on which account a fresh breeze usually counteracts the depressing influences of a sultry day. The opening day of the Exhibition under notice was one of the most brilliant days of summer, and the company was correspondingly brilliant, comprising as it did the *élite* of the town and neighbourhood. In the absence of the Mayor his deputy, Alderman Gallsworthy, accompanied by the municipal authorities of the town and representatives of the civic dignitaries of Leeds, formally opened the Show in the presence of a large assemblage of visitors.

The Show was both extensive and of general high quality; indeed many of the plants exhibited and much of the fruit were very superior, and we never observed at any show a less number of inferior exhibits. That was really the distinctive character of the display, and a most creditable one it is both to the several exhibitors and to the Society. The collections were arranged in three large tents, and were protected, as at York, by substantial barriers, while ample room was allowed for promenading, which is of the greatest importance in rendering a show enjoyable. The larger of the marquees presented an imposing appearance. It was not less than 300 feet long by 50 feet wide, and was well filled throughout. In the centre an elevated octagonal stage afforded accommodation for the specimen stove and greenhouse plants, and when it is stated that among the exhibitors were Mrs. Cole of Withington and Mr. Tudgey it will be admitted that the post of honour was well occupied. From the centre to one end of the marquee were arranged the ornamental-foliaged plants and Ferns, which were excellent. No staging was employed for them, and none was required, for the plants were sufficiently large when placed on the ground to fill the centre of the tent, and they always look much better when displayed on grass than on boards, particularly when the boards are not covered with calico or paper. The corresponding end of the tent contained what was a very strong point of the Show—namely, the collections of plants arranged for effect. Liberal prizes were offered in this class, and most gratifying was it to observe how admirably they were competed for. The unbroken masses were arranged down both sides of the marquee, the promenade being in the centre. It is doubtful if that is the best mode of arrangement. At Richmond (Surrey) the collections are grouped along the sides of the tent somewhat in the form of half circles, and from group to group narrow tables are placed close to the tent's sides, which accommodate some of the plants in the smaller classes, such as Achimenes, Gloxinias, table plants, &c., which do not require a great extent of space. Some form of arrangement showing the several collections more distinctly is desirable at Leeds; it is also very desirable that in addition to the liberal prizes offered in the "open" classes that a separate class be provided for amateurs and gentlemen's gardeners only. It is quite clear that there are those who can exhibit excellent examples of conservatory decoration at Leeds, and such as to merit some recognition which they cannot secure in competition with professional firms. Mixed groups arranged for effect are eminently suitable for local exhibitions, because they afford an opportunity for the exhibition of small as well as large plants, and thus the number of exhibitors is increased and taste in the arrangement of plants is stimulated.

A large side tent contained the fruit, Orchids, table plants, and an excellent display of cut Roses; and a corresponding marquee was admirably filled with Pelargoniums.

SPECIMEN PLANTS.—In the open class of twelve plants in flower the first prize of £12 was given by the Mayor of Leeds—Mr. Alderman Carbutt—and was won by Mrs. Cole & Sons, Withington, Manchester, with two large Azaleas, three fine *Ixoras*—Colei, Prince of Orange, and Williamsii—three good *Ericas*, *Statice profusa*, and a *Franciscea*, *Hedera*, and *Dracophyllum*—an excellent collection. Mr. Tudgey, gardener to J. Greswood Williams, Esq., Henwick Grange, Worcester, was a close second with plants not quite so large, but very fresh, well trained, and floriferous. Mr. Cottam, gardener to Mrs. Ringrose, Cottingham Grange, Hull, had the third prize with smaller plants,

In the amateurs' class for six plants three capital collections were staged, the honours going in the following order—first to Mr. Frankland, gardener to John Barran, Esq., M.P., Chapel Allerton Hall, Leeds; the second and third prizes being equally divided between Mr. Tudgey and S. Hanson, Esq., Green Mount House, Halifax. Mr. Tudgey staged *Allamanda grandiflora* in superior condition; *Ixora Williamsii* was also remarkably fine. The premier collection was composed of a splendid example of *Allamanda nobilis*—an oval 5 feet high, a *Bougainvillea glabra* of the same size, and somewhat smaller but good specimens of *Dipladenia amabilis*, *Clerodendron Balfourianum*, *Anthurium Scherzerianum*, and *Erica tricolor rubra*. In the class for three plants Mr. Wright, gardener to G. Talbot, Esq., Burley, Leeds, won chief honours with grandly-grown and well-furnished specimens of *Clerodendron Balfourianum*, *Stephanotis floribunda* 4½ by 3 feet and nearly faultless, and a very good example of *Gloriosa superba*. Mr. Hemming, gardener to H. Oxley, Esq., Wetwood, had the second prize, his noteworthy plant being the good old *Kalosanthes coccinea* 3½ feet in diameter and densely covered with flowers of unusual richness. Third honours went to Mr. Raper, gardener to J. Rhodes, Esq., Potterneton House, Leeds, who staged amongst other plants some very good Orchids.

ORNAMENTAL-FOLIAGED PLANTS AND FERNS.—These were remarkably well exhibited, and so close were several of the collections in point of merit that the Judges, Messrs. Baines and Penny, had considerable difficulty in making the awards. For six fine-foliaged plants Mr. Winterbourne, gardener to Thomas Simpson, Esq., Wetwood, Leeds, won the foremost position with two fine Palms, two Cycads, a *Dasyliroium*, and *Pandanus Veitchii*, all admirably cultivated. Mr. Cottam was second with excellent Palms, *Cycas revoluta*, *Phormium tenax variegatum*, and a remarkably fresh and well-coloured example of *Anthurium crystallinum*. L. Hanson, Esq., had the third prize with smaller plants, but for excellency of culture they were not surpassed in the Exhibition. They comprised *Latania borbonica*, *Cycas revoluta*, *Dracæna draco*, *Yucca filamentosa variegata*, and *Crotons majesticum* and *Johannis*. Mr. Raper exhibited remarkably well in this class, which was an excellent one.

Mrs. Cole & Son won the chief position in the class for six stove or greenhouse Ferns with a beautiful collection, consisting of a grand *Dicksonia antarctica*, *Thamnopteris australasica*, *Cibotium Schiedeii*, fine; and three *Gleichenias*—*speluncæ*, *rupestris*, and *Mendeli* in superb condition. Besides the first prize a bronze medal was awarded to this collection for excellency of culture. Mr. Eastwood, gardener to F. W. Tetley, Esq., Fox Hill, Leeds, was placed second with a grand *Cibotium Schiedeii*, *Alsophila australasica*, *Goniophlebium subauriculatum*, very good; *Lomaria gibba*, *Cibotium princeps*, *Dicksonia squarrosa*. Mr. West, gardener to T. Smith, Esq., Headingley, Leeds, won third honours, extra prizes being awarded to Mr. Hanson and Mr. J. Rhodes. Mr. Wright was first in the class for three fives with luxuriantly grown plants; Messrs. Tetley and Rhodes having the remaining prizes. All the competitors in the above classes exhibited highly meritorious collections. In the open class for twelve hardy Ferns Mr. C. Rylance and Mr. Goodchild, gardener to Mr. C. Naylor, Potterneton, Leeds, secured the prizes with very good collections.

ORCHIDS.—These were not numerous, but some superior examples were staged, especially by Dr. Ainsworth, Broughton, Manchester (Mr. Mitchell, gardener), who won the chief prizes in the classes for six and four plants. In the former class the notable plant was the magnificent specimen of *Vanda suavis* referred to in our report of the Manchester Show, and in the smaller class the plants were *Aërides Larpentæ*, *A. Schroderii*, *Cypripedium barbatum nigrum*, and *Thunia Bensoniæ*. The second and third prizes in the class for six plants were awarded respectively to John Barran, Esq., M.P., and J. Kitson, Esq. W. Bateman, Esq., had the second prize in the smaller class. Dr. Ainsworth also secured the chief prize in the single specimen class, followed by Mrs. Halliday, Armley Lodge, Leeds, and G. Talbot, Esq.

PELARGONIUMS.—These, though somewhat affected by the extreme heat of the weather, were extremely well represented. In the open class for twelve show varieties the prizes were awarded to Mr. May, Hope Nurseries, Bedale; Messrs. T. Lazenby & Son, Clarence Nurseries, York; and Mr. C. Rylance, Aughton Nurseries, Ormskirk, in the order named, who all staged admirable specimens. In the amateurs' class for six plants Mr. Winterbourne, gardener to W. L. Joy, Esq., Wetwood Mount, Leeds, won chief honours with luxuriantly-grown and very fine examples, F. W. Tetley, Esq., being second with smaller but well-grown plants. Messrs. Rylance and Lazenby won the prizes for floriferous plants of the French decorative varieties. In the open class for Fancies the prizes were equally divided between F. W. Tetley, Esq. and Mr. May for well-grown plants but fading. Mr. Winterbourne, gardener to W. J. Joy, Esq., was awarded first honours in the class for six Zonals or Nosegays for magnificent plants of Lord Derby, François Desbois, Mrs. W. Paul, Lucius, Cherry Cheek, and Pioneer. They exceeded 4 feet in diameter, and were dwarf and extremely fresh and well flowered. T. Simpson, Esq., and W. Oxley, Esq., had the remaining prizes in this class. R. Simpson, Esq., had the chief prizes for double varieties,

also for variegated sorts. Fuchsias, Calceolarias, and Azaleas were not noteworthy, but Gloxinias were excellent. For twelve plants the prizes went to Mr. Sunley, gardener to J. Kitson, Esq.; Mr. Sunley, gardener to W. Chambers, Esq., Clough House, Rotherham; and Mr. Backhouse, gardener to Dr. Gott, Woodslee House, Leeds, all the plants having remarkably fine foliage and numerous very fine flowers. Mr. Samuel May, Seedsman, Leeds, staged a box of cut blooms of Gloxinias inserted in wet sand representing a superior strain, the colours being extremely good and the flowers well formed.

Bedding plants were remarkably well exhibited. The twelve varieties with which R. Simpson, Esq., won the first prize were *Mesembryanthemum cordifolium* variegatum, *Alternanthera versicolor*, *Verbena International*, *Calceolaria Golden Gem*, *Nierembergia gracilis*, very fine; *Coprosma Baueriana* variegata, *Pachyphyton bracteosum*, *Lobelia Ebor*, very rich; *Coleus Beauty of Widmore*, excellent; and *Ophioglossum spicatum* aureo-marginatum, very beautiful. They were grown in pans 2 feet across, and presented quite a gay appearance. Messrs. Lazenby & Sons had the second prize, also with a capital collection. There was good competition in the class for six table plants, Mr. J. House, Eastgate, Peterborough, receiving first honours with *Dracæna Guilfoylei*, *Arecæ Verschaffeltii*, *Croton Disraeli*, two plants of *Cocos Weddelliana*, and *Aralia Veitchii*. Mrs. Cole & Sons were second, and Mr. Tudgey third. All the plants were good and of a suitable size for the purpose required—i.e., not too large.

PLANTS ARRANGED FOR EFFECT.—As previously observed these collections formed a prominent feature of the Show. The prizes offered were liberal and all the collections were meritorious, but more so, it must be observed, on account of the good quality of the plants than for their artistic arrangement, the groups being generally rather too crowded and too flat. The stipulated space was not to exceed 300 square feet, and the class was an open one. The first prize of £18 was won by Mr. Tudgey. It was evident that the Judges in awarding the prize considered, and rightly so, the pleasing appearance of the collection rather than the merits, as specimens, of the individual plants composing it. The plants, however, were excellently cultivated and choice, and were arranged in a free, light, and attractive manner. The second-prize collection of Mr. House was composed chiefly of remarkably well-grown, large, and formally trained specimens, which are most difficult to arrange picturesquely, hence they lost the premier position, but were awarded in addition to the prize a bronze medal for superior cultivation. Mrs. Cole & Son had the third position, and an extra prize was awarded to Mrs. Ringrose. Some other groups, notably those of John Barran, Esq., M.P., and T. Simpson, Esq., were highly meritorious in this excellent class.

ROSES.—Several plants were exhibited in pots, those from Mr. Pybus, Monckton Moor, Ripon, and Mr. May, who won the chief prizes, being very good indeed. Some excellent stands of cut blooms were also exhibited. Messrs. Cranston & Co., Hereford, won the chief prizes in the nurserymen's classes of forty-eight and thirty-six single blooms and twelve triplets with splendid collections, Messrs. Paul & Son, Cheshunt, being second in each class with admirable stands. Mr. May had the third prizes in the two first-named classes, and Mr. House in the twelve triplets. In the amateurs' classes A. G. Soames, Esq., Irnham Park, Bourne, won the first prize for eighteen blooms with a very good collection indeed. The prize was given by Mr. May. Mr. Soames was also considerably in advance of other competitors in the class for twelve blooms. The same exhibitor also won Messrs. Cranston & Co.'s for twelve blooms of Hybrid Perpetuals with a remarkably good collection, containing, however, a yellow Rose—a colour which has not yet been achieved in this section. Prizes were also offered by Messrs. Paul & Son, but we did not obtain the names of the winners of them. In the open class for twelve Tea-scented Roses three very fine collections were staged, and the prizes were awarded to Messrs. G. Paul & Son, A. G. Soames, Esq., and Messrs. Cranston & Co. in the order named. The two professionals always exhibit well, and we must congratulate Mr. Soames for the excellent position he obtained in such good competition. The blooms staged by this gentleman were very far in advance of those of the Yorkshire amateurs, who have evidently something to learn both in growing Roses and setting them up.

Splendid collections of stove and greenhouse cut flowers were exhibited by Mrs. Cole & Son and Mr. Letts, gardener to the Earl of Zetland, Upleatham, who won the chief prizes in the classes for them. The bouquets and stands of flowers were not remarkable for superiority of arrangement, and do not call for particular notice.

FRUIT.—The display was not extensive, but the produce generally was of superior quality. In the collections of six varieties Mr. Bannerman, gardener to Lord Bagot, Rugeley, won first honours with remarkably good dishes, consisting of a fine Pine; good Black Hamburg and very superior Muscat of Alexandria Grapes, bunches full, berries fine and admirably finished; excellent Royal George Peaches, well-coloured Elruge Nectarines, and a Trentham Hybrid Melon. Besides the first prize of £5 a silver Knightian medal was granted for the collection, the Judges considering that the Muscat Grapes alone well merited the special honour. Mr.

Wallis, gardener to Sir H. S. Thompson, Bart., Kirby Hall, York, was awarded the second prize for splendid and well-finished Black Hamburg Grapes and good examples of Chasselas Musqué, remarkably fine Strawberries, and good Peaches, Nectarines, and a capital Melon—a most creditable collection, and nearly equal to Mr. Bannerman's. Third honours went to Mr. Clark, gardener to the Marquis of Ripon, Studeley Royal, Golden Champion Grapes being very well exhibited in this collection. Grapes were generally excellent, some superior, especially the Black Hamburgs exhibited by Mr. Ferguson, gardener to B. Shaw, Esq., Selby, which not only secured the first prize in their class, but were also awarded a special silver medal, which they justly merited. The bunches were handsomely shaped and berries fine, regular, black, and well finished; they were indeed model bunches for dessert purposes. Mr. Sutton, gardener to H. Bentley, Esq., Woodlesford, had the second prize for excellent produce, and Mr. Johnson, gardener to Mrs. Noble, Boston Spa, was placed third for larger and capital examples, but not perfectly ripe, or they would have had a higher position in the prize list. In the class for the heaviest bunches Mr. Ferguson won chief honours with a remarkably good bunch of Black Hamburg weighing 3 lbs. 14 ozs., the berries being large, black, and well finished. Mr. North was placed second with the same variety, weighing 2 lbs. 7 ozs., and Mr. Clarke third, weight 2 lbs. 3 ozs., both bunches having good and well-finished berries. White Grapes were not noteworthy. Mr. Letts won the first position in the class for Melons with a fine fruit of Colston Bassett; Mr. Hinds, Otterspool, being second with Malvern Hall, large; and Mr. Wallis, Kirby Hall, third with Queen Emma. Peaches were good, the prizes going to Messrs. Clark, Sutton, and Purdy in the order named; and the prizes for Nectarines were won by Messrs. Wallis, Bannerman, and Clarke, the same exhibitors securing the prizes for Figs. A few very good Pines were staged, Mr. Letts securing the chief prize; and Mr. Hinds won first honours in the class for Strawberries with Sir C. Napier, Mr. Wallis being second with British Queen, and Mr. Clark third—all staging excellent dishes. A new, large, highly coloured, and good-flavoured Strawberry exhibited by Mr. Hinds was highly commended by the Judges.

The Exhibition was admirably managed by Mr. Clark, the Secretary, and an active Committee, whose great courtesy we desire to acknowledge. The elegant luncheon under the able presidency of Mr. Alderman Addyman was a pleasing adjunct to a successful Show.

BROCKHAM ROSE SHOW.

It falls to my lot as Judge to be present at many Rose shows, from the grand metropolitan fête in the Crystal Palace and Alexandra Park to the small country town in Scotland whither I hope to wend my way next month; but my experience of to-day is something quite novel—in a most charming place situated in the midst of the verdant Surrey hills. The grounds of Holmwood Park are opened by the kindness of Mr. Gough Nicholls to the members of the Brockham Rose Club. In a tent pitched under the wide-spreading Beeches are arranged the boxes which its members have entered for competition, and in an inner tent the various objects from which they are entitled to select their prizes, for no money is given at this Show; and altogether a more delightful reception of the queen of flowers cannot be imagined. As might be expected, as it is confined to amateurs living in the immediate neighbourhood, the Exhibition is not extensive, but evidently great care is taken by the exhibitors that the exhibits should be worthy of the occasion. Our friend the Rev. Alan Cheales, whom the readers of the Journal know so well as "A. C." and to whom so many feel indebted for the admirable rules for judging which mainly owe their existence to him, was *facile princeps*, his box of twenty-four containing some splendid blooms, and in his Teas and Noisettes some lovely examples of a very lovely class. The stands of twelve Madame Lacharme exhibited by Mr. Stone and of twelve Souvenir de la Malmaison shown by Mr. Mortimer were both so good that they received equal firsts. The blooms of Comtesse de Nadaillac, Climbing Devonians, and Madame Margottin in the winning stands were very good. The prizes were allotted thus:—Twenty-four single trusses—first, Rev. A. Cheales, second, Mrs. Mortimer. Twelve ditto—first, E. G. Stone, Esq.; second, George Drayson, Esq.; third, E. Horne, Esq.; fourth, Mrs. Seymour. Six ditto—Lady Mary Legge. Eight varieties, three trusses of each—first, E. Horne, Esq.; second, Rev. A. Cheales; extra, Mrs. Mortimer. Four varieties, three trusses of each—first, Lady Lawrence; second, Capt. Lang. Twelve trusses of any one kind—equal first, Mrs. Mortimer and E. G. Stone, Esq.; second, Lady Lawrence. Twelve Teas and Noisettes—first, Rev. A. Cheales; second, Mrs. Mortimer. Six Teas or Noisettes—first, E. G. Stone, Esq.; second, E. Horne, Esq. Best Tea or Noisette—first, E. G. Stone, Esq.; second, E. Horne, Esq. Best any other variety—first, Rev. A. Cheales; second, Mrs. Mortimer. One device of Roses and foliage—first, Mrs. Bruce Nichols. Device of any flower combined with foliage—equal first, Mrs. L. Gordon Clarke and Mrs. Benecke. Hand bouquet of Roses—Miss Cheales. Best buttonhole bouquet—first, Mrs. Bruce Nichols; second, Miss

Edith Cheales. Mr. G. Paul brought a box of new Roses from the Old Nurseries, Cheshunt, containing some fine blooms of his seedlings Sultan of Zanzibar, John Bright, Duke of Teck, Mrs. Laxton, Duke of Connaught, Marchioness of Exeter, &c.; and Mr. Henry Appleby contributed some cut blooms of Roses and also some plants from his nursery to decorate the tent.

I have many reminiscences of Rose shows, but certainly amongst the most pleasant of them will be the delightful day passed at Holmwood Park with all its lovely surroundings. The air of quiet and refinement that pervaded it was so thoroughly characteristic of the best kind of English country life, and the graceful hospitality of the owner added so much of pleasure to it, that I shall ever retain a most lively recollection of the day, and I can only hope that the Brockham Rose Club may have many years of increasing prosperity.—D., Deal.

ROYAL HORTICULTURAL SOCIETY.

JULY 2ND.

A VERY interesting meeting was held in the Council-room. It was not a "show," for there was no attempt at display, and nearly all the exhibits were either new or otherwise noteworthy. Plants, flowers, fruit, and vegetables were represented, and the meeting was of an essentially practical nature.

FRUIT COMMITTEE.—Henry Webb, Esq., V.P., in the chair. Mr. Wm. Chapman, gardener to the Marquis of Anglesey, West Park, Salisbury, sent a seedling Melon named "John Chapman," which was inferior in flavour. Mr. J. Dell, Stoke Rocheford, Grantham, sent a seedling Melon of great excellence. He stated in his communication that he had grown it for six years, and had found it very hardy and prolific. It has a smooth deep yellow skin, slightly netted, with a very small stalk and pale green flesh. It was awarded a first-class certificate, and the Committee named it Dell's Hybrid. Mr. H. A. Mann, gardener to Mrs. Hornsby, St. Vincent's, Grantham, sent a seedling Melon called Mann's Hybrid, but it was not of sufficient merit. He also sent a dish of Nectarines, to which a letter of thanks was awarded. Mr. E. Gilbert of Burghley Gardens, Stamford, sent a seedling Melon called Netted Victory. It is a fine, round, yellow, very thin-skinned green-fleshed variety, peculiarly and coarsely netted. It was of great excellence in flavour, and a first-class certificate was awarded. Mr. Gilbert also sent a red-fleshed variety called Lord Mayor, but it was not equal to the former. Mr. John Monro of Potter's Bar sent two seedling Melons; one, a red-fleshed variety called Lord Salisbury, was not of any merit; the other, Prince Bismarck, a white-fleshed variety, was also inferior.

Mr. Richard Gilbert sent specimens of Laxton's seedling Pea, "The Baron," one of those large-podded varieties like Superlative. He also sent Marvel, a fine-looking Pea containing as many as ten peas in a pod. It was certificated at Chiswick four years ago. Mr. H. J. Hardy, Stour Valley, Bures, Essex, sent specimens of Sequel Pea. This is said to be a free-bearer, and bears a considerable resemblance to a pure stock of Dickson's Favourite. Mr. Cowburn, Sunbury Park Gardens, sent specimens of Paris Green Cos Lettuce under the name of "Sunbury Park," and Mr. Turner sent specimens of a new early Potato called Early Bird.

FLORAL COMMITTEE.—Dr. Denny in the chair. Prominent amongst the plants exhibited was a collection of Lilioms, Colochortuses, and Freesias from the New Plant and Bulb Company, Lion Walk, Colchester. Amongst the Lilies were L. dalmaticum, stately and rich; L. japonicum colchesterii (Van Houtte), rich cream colour; L. Brownii, L. Harrisonii, L. parvum, L. Thunbergianum marmoratum flore-pleno, semi-double; and its dark variety Horsmanii, and the rich L. philadelphicum. Besides Freesia refracta, with its yellow lower segments, its variety F. refracta alba was exhibited and awarded a first-class certificate. It is a lovely flower for bouquets, a rival almost to the Stephanotis, and has a delicately primrose-like perfume. Calochortus venustus, C. luteus, and C. macrocarpus were very beautiful; and exceedingly rich—intense violet—was Tritelia laxa grandiflora.

Mr. J. R. Pearson, The Nurseries, Chilwell, Nottingham, exhibited four seedlings from Pelargonium echinatum—namely, Pixie, Hybridum, Ariel, and Beauty. The prevailing colour of the flowers is rose, with dark maroon spots on the upper petals, and white centres. The elegance and freedom of flowering of these plants render them very valuable for summer decoration; and it is quite refreshing to see such a collection after the plethora of Zonals, which are now almost bewildering by their numbers. Mr. Pearson's plants were highly commended by the Committee.

Some very fine Ivy-leaved Pelargoniums were exhibited by Mons. V. Lemoine, 67, Rue de l'Etang, Nancy, to two of which—Elfrida, deep rosy lilac, and Lucie Lemoine, bluish suffused with pink—were awarded first-class certificates. The flowers are very large and the trusses are good, and these varieties cannot fail being valuable for decorative purposes. A first-class certificate was also awarded to the double variety A. F. Barron, which has been previously exhibited and referred to.

A cultural commendation was awarded to Mr. Heims, gardener to F. A. Philbrick, Esq., Avenue Road, Regent's Park, for a splendidly grown example of Cattleia gigas with thirteen grand

flowers, one of the finest plants of this rich Orchid ever seen. Messrs. Chantrier freres, a Montefontaine, Oise, France, sent Croton Baron James de Rothschild, a very robust variety with yellow and crimson veins. It was passed by the Committee, perhaps on account of its somewhat coarse appearance.

Several new Roses were submitted to the Committee. Mr. Turner exhibited Dr. Sewell, a rich velvety Rose of the colour of Xavier Olibo; petals smooth and of great substance, slightly reflexed, and blooms of excellent form—a splendid Rose, which secured a first-class certificate. A similar award was granted to Penelope Mayo, which was shown in a style we have not before seen, and was superb. Another remarkably fine Rose was exhibited by Mr. Turner—namely, Harrison Weir, a rich, full, solid Rose that will be heard of again. Its colour is extremely bright crimson scarlet, and the petals are of great substance. Messrs. Paul & Son, Cheshunt, exhibited Charles Darwin, a rather small, well-shaped, richly coloured crimson Rose, which appeared identical with one named Congress in Mr. Turner's stand. Messrs. Paul also exhibited Duke of Teck, too small for exhibition, but a valuable garden Rose, deep carmine; also Countess of Darnley, a full Rose of excellent form, very deep rose colour, and highly promising. Messrs. W. Paul & Son, Waltham Cross, exhibited their fine new Rose Duchess of Bedford, which has been previously described, and a first-class certificate was awarded for it; they also exhibited an attractive box of May Quennell, good blooms of Dudley Baxter, and a few others. Mr. C. Noble, Bagshot, exhibited blooms of the floriferous crimson bedder, and also of an unnamed seedling Rose raised from Maurice Bernardin. The new Rose is remarkable as having the refreshing perfume of the old Provins Cabbage Rose, which is not contained, so far as we are aware, by any other crimson Rose.

A splendid collection of Verbenas was exhibited by Mr. Cannell, Swanley, Kent—Beauty of Langleybury, lavender blue, edges of petals pure white, well defined; Pretty Mary, maroon, rich; Spitfire, scarlet; La Lovie, pale blue, white eye; Neptune, plum, white eye; Isa Brunton, purplish plum, white eye; Annie, cerise and white striped; Lord Cranbrook, immense truss and pips rose purple, are a few of the more noteworthy varieties in this fine collection, which was highly commended. Mr. Smith, Tollington Road, Nurseries, exhibited dwarf striped double, semi-double, and single Petunias, which were highly commended. Mr. Cauldwell, The Ivies, Wantage, exhibited a good strain of Auricula-flowered Sweet Williams, also good Antirrhinums. Mr. Dean also exhibited good and brightly-coloured Sweet Williams. G. F. Wilson, Esq., F.R.S., was awarded a vote of thanks for blooms of the beautiful Lilium Kramerii, showing its different shades of colour, also varieties of L. pardalinum. C. Pache, Esq., Brighton Road, Birmingham, sent plants of a Pelargonium well named Golden Jewel, for it has foliage resembling that of Golden Chain, with the symmetrical double flowers of the well-known variety Jewel. Mr. R. Parker, Exotic Nursery, Tooting, exhibited Umbilicus Sempervivum, and Lilium martagon plenum, very double and fine. Messrs. J. Laing & Co., Forest Hill, sent Gloxinia Papillon, a charmingly spotted variety, very attractive; and Messrs. James Carter and Co., exhibited scarlet Eschscholtzia Mandarin, and a lacinated variety of Phlox Drummondii.

From the Society's Gardens at Chiswick came well-flowered examples of Torenia Fournieri. The plants have been grown under cool treatment and were laden with richly coloured flowers. This is the most valuable annual of recent introduction, and will find its way into most greenhouses and flower markets.

IMPRESSIONS OF THE NATIONAL ROSE SHOW.

THAT it was a great success, that this was greatly owing to the admirable arrangements of the Hon. Secretaries; that it is a wonderful season for Tea Roses; that such a box as Mr. Cant's twelve Boule d'Or was never seen of the kind before, and how does he manage to get that hard-hearted Rose to open herself to him? that Horace Vernet and Marie Baumann were represented in perfection; that Capt. Christy's new seedling brought out by Messrs. Paul & Son is of great promise; that Jean Liabaud, though wonderful in colour, is inferior in form to good old Camille de Rohan, and that the latter ought to be shown more than it is; that this is a Le Havre year, which is a Rose that everyone ought to have; that the Crystal Palace is perfection for a Rose show with perfection weather; finally that it will be all in our Journal, and that everyone is wanting to see the account.—A. C.

KINGSTON AND SURBITON HORTICULTURAL SOCIETY.—JUNE 26TH.

THE fourteenth annual Show of this excellent Society was held at Norbiton Park on one of the hottest days on record. Stove and greenhouse plants are as a rule well exhibited at this Show. Mr. Hinnell, gardener to F. A. Davies, Esq., Surbiton, was awarded

the first prize for nine plants; Mr. Croxford, gardener to Mrs. Dunnage, Surbiton, the second; and Mr. Moorman, gardener to Miss Christy, Coombe, the third. In the class for six plants T. V. Sutton, Esq., Gibbon Road, Kingston, won first honours for a very even and well-bloomed collection; Mr. Crafter was placed second; and Mr. Watson, gardener to — Bryant, Esq., first for three plants.

Six exotic Ferns came from Mr. Hinnell; Mr. Attrill, gardener to J. C. Freake, Esq., Bank Grove, Kingston; and Mr. Crafter, gardener to the Rev. W. Finch, Woodlands, Kingston Hill, who were placed in the order of their names; and for three plants Mr. J. Watson, gardener to Capt. Cundy, Mr. Moorman, and Mr. R. Watson divided the honours between them.

The class for nine Fuchsias was a very good one, Messrs. R. Watson, Moorman, Beckett, and Crafter being the principal winners.

In the Pelargoniums there was a considerable falling-off in numbers of exhibitors of these plants. The collections staged by Mr. Croxford were good, and well deserved the awards given to them—three first prizes and one second. Mr. Beckett, gardener to J. C. McConnell, Esq., Esher, also exhibited well in the classes for nine and six Show and Fancy varieties.

Six very tasteful groups of plants for effect were set up for the President's prize. Mr. Attrill was awarded the first prize, Mr. R. Watson the second, and Mr. Buckland the third; and for the prizes offered by Sir Trevor Lawrence, Bart., for a single specimen plant in flower Mr. Moorman won the first prize with a very large *Bougainvillea glabra*, Mr. Buckland the second with a well-bloomed *Stephanotis*, and Mr. Hinnell the third prize with a neat plant of *Dracophyllum gracile*.

For cut Roses the heat was most trying, especially to those who had a distance to bring their blooms. Mr. Moorman was a good first for twenty-four Roses, distinct; Mr. Mace, gardener to Capt. Eastwick, Teddington, occupying the second place; and Mr. Gray, Ditton Hill, the third. For twelve blooms Mr. Crafter was placed first and Mr. L. Stephenson second.

Fruit was very well shown, Messrs. Attrill, R. Watson, Croxford, and Child taking the principal prizes.

Vegetables were also very good and numerous exhibited; Mr. Moorman, Mr. Croxford, and Mr. Buckland being placed first, second, and third respectively for twelve sorts; and Mr. Crafter, Mr. Pavey, and Mr. Beckett for six sorts, were placed in the order of their names.

Dinner-table decorations were as usual well done, Mrs. Clay and Mrs. McConnell taking the two leading first prizes.

The productions exhibited by amateur growers were better than are often seen at local shows, Mr. Nagle and Mr. Sutton taking the lion's share of the prizes. Cottagers were also in great force, and right well do they take the advantage of classes open to them, there not being a class set apart to them but what was full to overflowing.

NOTES AND GLEANINGS.

ONE of the most attractive objects in the meeting hall of the Royal Horticultural Society on Tuesday last was a PORTRAIT OF THE REV. M. J. BERKELEY, painted by Mr. J. T. Peele of Fitzroy Street, Fitzroy Square. The portrait is an admirable one, and is a faithful representation of one whose name will be a lasting one in the annals of natural science. The ultimate destination of the picture is the rooms of the Linnæan Society at Burlington House, but it will remain at South Kensington for a few weeks in order that the friends and admirers of the gifted philosopher may have an opportunity of seeing it, and of testifying the regard in which they hold him, by sending their contributions to the portrait fund, either to the Treasurer, Dr. Hogg, 99, St. George's Road, Eccleston Square, S.W.; or to Dr. M. T. Masters, 41, Wellington Street, W.C.

THE MAIDSTONE SHOW held on the 26th ult. was, we are informed, an excellent one. Very good collections of plants were staged by J. W. Braddick, Esq., Lady Howard de Walden, Major Best, Captain Brenchley, G. A. Dodd, Esq., Rev. Stuart Robson, and others. The Misses Jones and Mr. Pearce were the chief exhibitors of cut flowers. Roses were not quite so numerous as usual. F. Warde, Esq., of Farleigh, gained the first prize for twenty-four varieties, while L. A. Killick, Esq., was awarded first prize for twelve varieties, and J. Holingworth, Esq., first in the China, Noisette, Tea, or Bourbon classes. The vegetables were well represented. Fruit was not sent in large quantities, but a bunch of Grapes exhibited by W. Laurence, Esq., and which gained the first prize, was excellent. The Peaches and Nectarines sent by Capt. Brenchley were also very fine.

THE third summer Exhibition of the BRIXTON HILL STREETHAM, AND CLAPHAM HORTICULTURAL SOCIETY was held on Wednesday and Thursday, June 26th and 27th. The

Exhibition, we are informed, was a good one, but owing to the lack of interest taken in the Society's efforts to hold a summer Show in addition to their annual autumn Show, by the inhabitants of the neighbourhood, the Society cannot, we regret to say, be congratulated on scoring a financial success. There was good competition in the plant and fruit classes, and vegetables of excellent quality were exhibited. A Society which embraces within its limits so many good gardeners who are anxious to stimulate each other in the work of superior cultivation, merits the support of the affluent of the district. Mr. R. Hall is the Secretary of the Society.

AT Orton Hall, near Peterborough, the beautiful seat of the Dowager Marchioness of Huntley, we saw the other day the finest plant of LAMARQUE ROSE that ever came under our notice. It is growing near and is trained to the south wall of the kitchen garden, and is evidently of great age, for its stem resembles that of a timber tree. The branches cover over a great extent of wall, and the tree—for tree it is—bears annually many hundreds of charming blooms. A specimen such as this is highly worthy of being covered with glass, for apart from the value attached to so old and fine a tree, the blooms it produces if valued commercially would soon more than compensate for the cost of the structure necessary for its preservation.

BEFORE our next issue the great horticultural Show of the year—namely, the PROVINCIAL SHOW of the Royal Horticultural Society, will have opened at Preston. The superior examples of culture of plants, flowers, fruits, and vegetables that will be displayed in competition, and the various articles that will be on view, such as implements, garden structures and requisites in their most improved forms, afford an opportunity for gardeners and all interested in horticultural pursuits for obtaining information and gathering instruction such as seldom occurs. We are glad to learn that many employers are making arrangements for enabling their gardeners to attend the Show, for a visit of gardeners to Preston next week cannot fail to be of mutual advantage both to them and to their employers.

IF we may judge by the great number of FLOWER SHOWS now occurring an unusual amount of interest must be taken in gardening pursuits. Perhaps among no class of men is such a spirit of emulation existent as among gardeners and amateurs engaged in gardening; and to encourage such who are endeavouring to improve themselves and to advance the work with which they are identified, we have given this week a larger share of space than usual in recording the honours won by skilled cultivators in various districts. Very glad are we to note the general excellence of the exhibits at many local shows. Exhibiting when not overdone—*i.e.*, made a trade of, is an agreeable mode of relaxation, and is a valuable means of affording practical instruction, leading directly to improved cultivation and the better management of gardens under the influence of the several horticultural societies which are established throughout the country.

THE following suggestions, says the "Journal of Forestry," will enable one to MEASURE THE HEIGHT OF A TREE or other standing object near enough for practical purposes. Place a small mirror in a level position on the ground at a little distance from the tree, then step backward until the top of the tree is reflected in the centre of the mirror. The height of the tree equals your height multiplied by the distance of the tree from the mirror, divided by your distance from the mirror.

EUCALYPSINTHE.—This is the name of a new French beverage prepared from the Gum Tree (*Eucalyptus*). It is said to be obtained by distillation from the leaves, and to be at once grateful to the palate, exhilarating, and not only quite harmless but possessing many useful medical properties. This new beverage appears to be largely made and consumed in Marseilles.

PEACH-GROWING has increased to such an extent within a few years as to become a leading interest in fruit culture. The Peach can be successfully cultivated almost anywhere south of 42°, and below an altitude of 9000 feet. Just before the ripening season there is much solicitude among growers. Thousands of baskets of Peaches have been known to rot on trees in Delaware in a single warm wet day from the want of dry air and sun. It is claimed that few crops give so large and quick returns for the capital and labour invested as the Peach. The Peach business has reached massive proportions. One leading Boston commission house last season sold \$140,000 worth of the fruit, and smaller concerns averaged

from \$20,000 to \$5000. Nearly all the Peaches received in Boston come by rail by quick Peach-train transit, avoiding New York. Last season the daily newspapers published interesting stories respecting these Peach trains.—(*American Cultivator*.)

THE ROYAL HORTICULTURAL SOCIETY'S PROVINCIAL SHOW AT PRESTON.

CONSIDERABLE progress, we are informed, has been made with the work connected with the holding of the great Show in the extensive grounds adjoining the Preston Pleasure and Nursery Gardens at Ribbleson. The site to be occupied by the grand pavilion is now nearly completed. The mounds upon which the plants are to be arranged are now turfed and present a very effective appearance; the pond has been constructed and filled with water; and the artificial waterfall,

which has been ingeniously and artistically devised, is in a very forward state. All this work is from the designs of Mr. J. F. Johnson, landscape gardener, of Belfast, and late curator of the Botanic Gardens in that town. The uprights for supporting the canvas of the pavilion, and which will be covered with creeping and other plants, are now erected, and in a few days everything will be in order for the reception of the exhibits. Over the large pond at the entrance of the grounds Mr. H. Inman, of Stretford, near Manchester, is now throwing a pretty bridge, and when completed it will present a very picturesque object in the view. The sides are formed of gnarled pieces of polished wood of fantastic shapes, and altogether it is a very ingenious construction.

Mr. Barron with his foreman and some men have arrived, also 10 tons of poles and canvas. The large tent and its adjuncts are ready for the canvas, the walks all gravelled, and by the time will be well set with watering and rolling. Mr. Troughton, the

Fig. 1.—PLAN OF THE SHOW GROUND AT PRESTON.

Manager of the Preston Nursery Company, has had the town water laid where necessary, so that this item will not fall short however hot the weather. The whole field is now being mown over. About forty greenhouses are being erected, and nearly all are being glazed and painted; some are expensive, being filled with stages and piping by Messenger & Co., Richardson and Co., Halliday & Co., Perry, Webster, Cranston & Luck, and Thorley. Boilers, tents, wire work, rustic work, and other garden requisites are represented.

The suite of offices are nearly complete, including post and telegraph offices, wires being laid from the town to the ground. There are rooms for Exhibitors, for the local Committee, the Press, the London Council, the local Council, the Secretaries and Clerks, and all other necessary conveniences.

Mr. Troughton has made a good and firm road to the tents 24 feet wide, so that vans can move easily. The entries we understand are very numerous, and everything is in a forward state, and a great and good Show is anticipated.

The main entrance to the Exhibition will be through the gates of the Preston Nursery Company, the Manager of which has charge of the ground.

The accompanying outline plan of the Show ground will afford a general idea of the arrangements and preparations for the approaching great horticultural gathering of the year.

1, Approach through the nursery; 2, First-class refreshments;

3, Second-class refreshment; 4, Circular tent; 5, Fruit; 6, Table plants; 7, Cut flowers.

WIMBLEDON HORTICULTURAL SOCIETY.

JULY 2ND.

THIS Society held its sixth annual Exhibition in the beautiful grounds of Wimbledon House, kindly lent by Sir H. W. Peek, Bart., M.P., who is also the President of the Society. Stove and greenhouse plants were fairly well exhibited. Mr. W. Smith, gardener to G. C. Joad, Esq., Oakfield, was awarded the first, and Mr. Moorman, gardener to Miss Christy, the second prize. In the class for four plants Mr. Bentley, gardener to Sir Thomas Gabriel, Mr. Lyne, gardener to A. Schlusser, Esq., and Mr. Stratton, gardener to Miss Forbes, were placed in the order of their names.

Fuchsias were very well shown, and the competition was very close between Mr. Stratton, Mr. Lyne, and Mr. Moorman, who were placed first, second, and third respectively. Caladiums were well exhibited by Mr. Stratton and Mr. Lyne, and the best six Ferns came from Mr. Bentley, who exhibited an admirable collection, Mr. Smith being placed second with plants almost equal to them. There were five competitors in the class for four Ferns, and the collections were very evenly matched, Mr. Lyne being awarded the first prize, Mr. Bridger the second, and Mr. Moorman the third. Gloxinias were better exhibited than we usually see them, Mr. Lyne staging some excellently grown plants. Zonal Pelargoniums were grand, Mr. Lyne occupying the first place for

six plants, and Mr. Stratton the second. Doubles were much finer and better bloomed than it is customary to find them, the same exhibitors occupying the same position as for six Zonals. Table plants were well shown, and the best twelve came from Mr. Smith, the second best from Mr. Lyne, and the third from Mr. Stratton.

ROSES were, considering the heavy rains of Sunday and Monday night, very well exhibited, twenty collections being staged. For the special prizes offered by Sir Trevor Lawrence, Bart., Mr. Moorman easily won the first prize, Mr. J. Clark the second, and Mr. J.

Reddin, gardener to E. Reeves, Esq., third. For twelve blooms (special given by C. J. Dickens, Esq.) Mr. Scott, Clinton Villa, Wimbledon, took the first prize with an exquisite collection. The best collection of twenty-four in the gardeners' class was staged by Mr. Moorman, and the first prize for twelve was taken by Mr. J. Curtis, gardener to W. Barlow, Esq., Atherton Grange. Mr. J. E. Coleby had the first prize in the amateurs' division.

Both fruit and vegetables were excellently exhibited, but the judging was not completed when our reporter left the grounds.

We noticed spirited competition among the cottagers, whom

Fig. 2.—RHODODENDRON FRAGRANS.

this Society greatly encourages in the shape of numerous special and other money prizes provided.

RHODODENDRON FRAGRANS.

We figure this *Rhododendron* because it is not so well known, or at any rate so extensively cultivated, as its merits deserve. In the collection of Mr. Anthony Waterer, that has so long produced such a gorgeous effect in the gardens of the Royal Botanic Society at Regent's Park, *R. fragrans*, one of the smallest of all the varieties exhibited, was certainly one of the most generally admired. Its flowers are chaste in form, pleasing in colour (deep rosy pink with nearly white centre), and they are deliciously fragrant. Attractive as they are in appearance their delightful perfume is their chief charm. In this

respect they are surpassed by no other *Rhododendron*, and are equalled by few; they are, indeed, as sweet as the Honeysuckle. The habit of the shrub is dwarf and compact, and it flowers with the greatest freedom. For front rows in shrubberies, where *Rhododendrons* and American plants thrive, *R. fragrans* should have a place, and it is equally valuable for conservatory decoration. It is one of the most distinct and useful varieties—for we believe it is a hybrid—of the handsome genus to which it belongs, and cannot fail to give satisfaction wherever it is well grown.

FUCHSIA RICCARTONI.—In the gardens at Orton Hall, Peterborough, we recently met with what is not commonly found in the eastern or midland counties of England—namely, a large

specimen of this valuable Fuchsia, which has evidently passed through many winters uninjured. We have seen this beautiful old Fuchsia in "tree" form in a few gardens on the south coast, also in some gardens in sheltered districts in Scotland, but have never before met with one in the somewhat flat, cold, and low-lying district in which this specimen is growing. The secret of its preservation is probably owing to its local position, for it is growing on a pile of rockwork. There it not only does not make luxuriant and consequently tender growth, but its clusters of coral-like flowers are seen to great advantage. The fact that this plant has existed so long and thrives so well on its artificial altitude in a cold and flat district, suggests a means of growing this beautiful old Fuchsia in other gardens to which it is now a stranger. The plant is very valuable for affording cut sprays for vase decoration.

ROMFORD HORTICULTURAL SOCIETY'S SHOW.

THE annual Show of the above Society was held on the 27th ult. in the grounds of C. P. Matthews, Esq., The Bower, Havering. This gentleman's picture gallery was also thrown open to the visitors, and proved to be a source of great attraction. The Show, held in a most picturesque spot, was scarcely so good as usual, at the same time it was a very creditable Exhibition.

In the class for eight stove or greenhouse plants in flower Mr. Lane, gardener to General Fytche, Pyrgo Park, was first, and Mr. Bones, gardener to D. McIntosh, Esq., Havering Park, was second. Mr. Lane staged a very even group, not large, but well-flowered specimens. In the corresponding class for four varieties Mr. Douglas, Loxford Hall, was first, and also for six Orchids, in the latter staging good examples of *Dendrobium nobile*, *formosum*, and *giganteum*; *Lælia purpurata*, *Odontoglossum Alexandræ*, *Stonei*; and *Masdevallia Harryana*. For six Cape Heaths Mr. Bones was first, and Mr. Lane second. Mr. Douglas was first for six foliage plants, and Mr. Lane second. The last-mentioned exhibitors occupied the same positions in the class for six Lycopods. For six exotic Ferns Mr. Douglas was first, and Mr. Woodhams, gardener to C. P. Matthews, Esq., second. Mr. Bones was first for six large-flowering and also for six fancy Pelargoniums. There were also classes for Fuchsias, Gloxinias, Coleuses, Caladiums, double-flowering Zonal and Tricolor Pelargoniums, but the specimens staged were in most instances very poor. Mr. Meadmore, nurseryman, Romford, won the first prize for the most tastefully arranged basket of plants.

There were classes for cut Roses, but the competition was very limited. For forty-eight blooms Messrs. Saltmarsh & Son, Chelmsford, were first, and Mr. Meadmore second; the former had good blooms of *Capitaine Christy*, *Comtesse de Serenye*, *François Michelin*, *Elie Morel*, *Madame Ferdinand Jamin*, *La France*, *Mdlle. Marie Cointet*, *Rubens*, *Souvenir d'un Ami*, &c. Mr. Pemberton was first for twenty-four, and Mr. Nairn second. Mr. Pemberton was also first for twelve, and was also commended for a box of eighteen cut blooms of *Marquise de Castellane*. Mr. Pemberton's exhibits were remarkable for their freshness and good colour. Messrs. W. Paul & Son, Waltham Cross, staged five boxes of cut Roses, not for competition, which were highly commended by the Judges and much admired by the visitors. All alike were good, the following especially so:—*Amélie Hoste*, *Annie Laxton*, *Capitaine Christy*, *Comtesse d'Oxford*, *Duchesse de Caylus*, *Edouard Morren*, *Madame Lacharme*, *Mdlle. Eugénie Verdier*, *Marie Baumann*, *Marquise de Castellane*, *Princess Beatrice*, &c.

The fruit, notably the Strawberries and Grapes, made a good display and attracted much attention. For a collection of six varieties of fruit Mr. Bones was first and Mr. Lane second. Mr. Bones had good Black Hamburg and Muscat of Alexandria Grapes, Blood Pine, City Feast Melon, Peaches, and Nectarines. There was good competition in the class for black Grapes, all staging Black Hamburgs good in bunch and berry, but in several instances the colour was wanting, the only exception being those staged by Mr. Douglas and placed second; Mr. Tarance, Chadwell Heath, being first. Mr. Douglas was first for white Grapes with good Muscat of Alexandria, and Mr. Lane was second. For three varieties Mr. Douglas was first, staging good examples of Canon Hall Muscat, Black Hamburg, and Buckland Sweetwater. Mr. Worthing, gardener to A. Moss, Esq., Chadwell Heath, was second. Mr. Bones was first for Peaches, staging a good dish of *Violette Hâtive*; second, Mr. Worthing. Nectarines were poor, and no first prize was awarded. Mr. Lane was first, and Mr. Iggulden, gardener to R. B. Wingfield Baker, Esq., Orsett Hall, secured the prizes for Melons. Strawberries were staged in large quantities, some of them being very fine. Some of the exhibitors were evidently too fond of monstrosities; not so, however, the Judges, preference being given to perfect-shaped fruit. For three varieties Mr. J. Smith was first with good dishes of Sir J. Paxton, Dr. Hogg, and James Veitch; Mr. Groom was second.

The vegetables collectively made a good display, but some of the exhibits were very poor indeed. In the gardeners' class for eight varieties Mr. Iggulden gained the first prize with a very

credible and much-admired basket, made up with the following varieties:—Globe Artichokes, Vick's Criterion Tomatoes, Hamersmith Kidney Potatoes, Nantes Horn Carrots, Early London Cauliflower, Seville Longpod Beans, Culverwell's Telegraph Pea (the finest Pea in the Show), and the American Strap-leaf Turnip. Mr. Lane second. There were five competitors in this class. Mr. Douglas was first for a brace of Cucumbers with Tender-and-True, and Mr. Worthing second. Mr. Iggulden was first for kidney Potatoes, var. *Mona's Pride*; Round Potato Alpha; Turnips, Sutton's Snowball; Lettuce, Scott's Superb; and Peas, Huntingdonian. Mr. Lane was first in the remaining classes. Both the amateurs and cottagers staged some very creditable vegetables, and the former fairly eclipsed the gardeners with vases, button-hole bouquets, &c.

BRIGHTON SUMMER SHOW.

On last Wednesday and Thursday in sultry weather the Brighton Summer Show was held at the Pavilion. The Exhibition was a good one, plants, cut flowers, and fruit with few exceptions being excellent, the prizes in all the classes being fairly well contested; and what was perhaps even more important, the space provided for the various exhibits was well filled—no small matter in these days of defaulters, who at the last moment so frequently upset the well-planned arrangements of the Secretary and often spoil the show.

The plants were the leading feature; most of them were good, and some were of much excellence. Mr. W. Balchin, Hassocks Gate, Cliftonville, carried off the first prize for eight fine-foliaged plants with a magnificent *Cycas revoluta* with a dense head of dark green spreading frondage, quite 12 feet in diameter and without a blemish; a huge example of *Croton pictum*, wonderfully rigorous but not in good colour, much of the young foliage being of a pale yellow; *Areca sapida*, with large, fresh, and quite young frondage; *Pandanus Veitchii*, in which size had also been acquired at the expense of colour; an excellent *Latania borbonica*, a huge *Croton variegatum*, a fine example of that very ornamental *Cycad Encephalartos villosus*, and a really magnificent *Croton majesticum* quite 2 yards in diameter and as much in height and splendidly coloured. The second prize was taken with a creditable display, including fine examples of *Latania borbonica* and *Dracæna Cooperi*, by Miss Brodie (gardener, Mr. C. Driver). Mr. W. Miles was third, and had a very fine highly coloured plant of *Alocasia macrorrhiza variegata*.

In the class for foliaged plants by local growers Miss Brodie came first with four good but unequal-sized plants, of which an *Anthurium crystallinum* with ten fully developed leaves each about 18 inches by 12 was very beautiful. The second-prize group, which went to C. Armstrong, Esq. (Mr. E. Meachin, gardener), contained a grand example of *Pandanus Veitchii* in splendid colour; and in the third-prize group a *Caladium Prince Albert* Edward was striking, not only by its large size but the richness of its leaf tints—green intermingled with silvery white, charmingly suffused with delicate pink and with veinings of deep rich pink.

In the open class for specimen plants in bloom Mr. Balchin was also first with an *Ixora javanica floribunda* in fine bloom. The plant was pyramidal in shape, 5 feet high, and some 6 feet in diameter at its base. The second prize was awarded to the Duke of Richmond, Goodwood (gardener, Mr. F. Rutland), for a large *Anthurium Scherzerianum* with about three dozen spathes not quite all open. The third prize went to F. Shenstone, Esq. (gardener, Mr. A. Venall) for an *Allamanda*.

Mr. W. Balchin again stood first in the open class for eight exotic Ferns, and deservedly so, for his plants were all fine, forming a bold and graceful group. *Davallia pyxidata* was 6 feet in diameter. Then there was a capital *Dicksonia*, a *Gymnogramma Martensii*, the twining-stemmed *Cyathea Dregei* so attractive by the purple tinge of its fronds, a *Cibotium regale*, and an *Adiantum Sanctæ-Catherinæ*. In the class for local exotic Ferns Miss Brodie, Eastbourne, came first with a very fine Golden Fern (*Gymnogramma Laucheana*), a still finer Silver Fern (*G. peruviana argyrophylla*), a *Lomaria gibba*, and a *Dicksonia*. A display of hardy Ferns by Messrs. James Ivery & Son, Dorking, consisting of some seventy plants, was a prominent and attractive feature, to which an extra prize was deservedly awarded.

The Orchids were none of them large. Mr. Rutland came first in the open class with eight good plants, the best of which were *Brassia versicolor* with seven spikes, an excellent *Cypripedium barbatum* with about two dozen of its charmingly pencilled flowers, and a good-sized plant of *Lycaste aromatica*. Mr. Meachin's six plants stood first in the local class. His *Lælia purpurata* with four large spikes was very good.

There is always a goodly display of Begonias at Brighton. F. Shenstone, Esq., Barcomb (gardener, Mr. A. Venall), came first with four tall plants in fine flower but somewhat wanting in form. The second-prize plants were of better form, but unfortunately betraying a little too much floral millinery. Of Fuchsias there were several groups, none of them really good, the whole being deficient in finish and uniformity.

The whole of these plants were in the pleasant cool rooms of

the Pavilion and the remainder were in a tent on the lawn. Our inspection of them was a brief one, for the tent was excessively hot, there being no ridge ventilation, and the flowers suffered very much—so much, that when our notes were taken on the second day of the Exhibition hardly a Rose was recognisable, so much were they faded. This state of things should and could be altered by using a tent with a ridge ventilation similar to that of the Bath and West of England Society. Of the plants in the tent the most noticeable were a magnificent *Pimelea decussata* by Mr. Meachin, who took first for local stove and greenhouse plants, having also a very good *Plumbago capensis* and a magnificent example of the popular *Bougainvillea glabra*. Mr. Balchin had good plants of *Erica Cavendishii* and *Dracophyllum gracile*.

In Pelargoniums Mr. W. Miles, West Brighton Nursery, stood pre-eminent, his six fancies which gained the first prize in the open class being so good that we give the names:—Victor Hugo, Princess Helena, The Rover, Countess of Dudley, Evening Star, and Mrs. Hart, the first, third, and fifth being dark and the other three light kinds. Mr. Miles also took first prizes for large-flowered Pelargoniums and zonal Geraniums, Mr. Meachin taking first for Pelargoniums in the local class.

Cut Flowers.—Of these there were Roses, Messrs. Mitchell, Piltown, Uckfield, winning the Ashbury cup, value ten guineas, with seventy-two varieties; Mr. Piper, nurseryman, Uckfield, being second, and Mr. W. Balchin third. In Teas Messrs. Mitchell were first, and amid all the fading flowers their Madame Margottin, Adrienne Christophle, and Souvenir d'Elise Vardon retained their freshness and beauty. In the class for twenty-four Roses Rev. R. C. Hales was first, and Mrs. Woolard, Cocksbridge, second.

The Veitch Memorial medal and prize of £5 for bridal and ball-room bouquets were won by A. J. Atkinson, Esq. (gardener, Mr. J. Hudson), with creditable bouquets. There were four competitors for this much-coveted prize, and most of the bouquets impressed us as being heavy and crowded. In the class for dinner-table decorations of wild flowers Miss Chilmaid of Keymer came first with three very pretty stands both light and tasteful. The first prize for stands with exotic flowers was awarded to A. Allison, Esq. (gardener, Mr. R. Downing), for a central stand with three tiers somewhat overdone with spray, and two side stands consisting of round glass dishes, to each of which height was imparted by the stem and foliage of a young Palm cut off for the purpose; Mr. F. Gallop, Western Road, Brighton, taking the second prize, and Mr. Miles the third. Some pretty collections of cut flowers were shown, Mr. Rutland taking first and Mr. J. Holmes, Daneford Cottage, West Grinstead, second; Mr. Morse and Mr. Balchin also taking first and second prizes for cut flowers of a similar kind in another class. Mr. Cannell of Swanley Nursery had fine displays of cut Verbenas and zonal Geraniums, both gaining certificates of merit.

Fruit.—A small but choice exhibition of fruit was by no means the least striking feature of the Show. Grapes were very good. T. B. Heywood, Esq. (gardener, Mr. J. Ridout), truly winning a first prize with three bunches of well-coloured Black Hamburgh, Mr. Rutland being second; Col. Haddington, Hurst (gardener, Mr. H. Wickham), taking first for some excellent Muscat of Alexandria, Mr. Rutland being second. In local prizes some well-finished Buckland Sweetwater beat some much larger but unripe Muscats, and the black Grapes of W. L. Ewart, Esq. (gardener, Mr. J. Vickery), were worthy of the first prize awarded them. Peaches, Nectarines, Pines, Strawberries, and Melons were all well represented, the two first fruits being especially good.

RICHMOND HORTICULTURAL SOCIETY'S SHOW.

JUNE 27TH.

EVERY year this Society's Shows improve both in the number and quality of the exhibits, and the Society also enjoys the most distinguished patronage. H.R.H. the Prince of Wales intended honouring the Show with his presence, but at the last moment was prevented doing so; but those highly popular Royal personages the Princess Mary of Cambridge and H.S.H. the Duke of Teck and family were present during the afternoon, and spent upwards of an hour in inspecting the various exhibits. Previously to the departure of the Royal personages the Duchess of Teck handed to Mr. Chancellor, the indefatigable Hon. Sec. of the Society, a gold medal in commemoration of his active services in connection with this Show. The medal bore the following inscription:—"Richmond Horticultural Society. Presented to Mr. Albert Chancellor in recognition of his services in promoting the formation of the Society, 1875."

The Exhibition was a very large one, and consisted of 140 classes. The productions exhibited for the numerous special prizes had a large tent especially devoted to them; it had also the most pleasing effect of any tent in the Exhibition. A second tent was set apart for cut Roses and other cut flowers; a third, 170 feet by 54, contained the groups and the larger collections of flowering and foliage plants; in a fourth were the collections of fruit and vegetables; and a fifth contained the cottagers' productions. The weather was oppressively hot, but under the shade of the fine

trees which abound in the old deer park there was a most refreshing breeze.

Class 1 was for a group of plants arranged for effect in space not to exceed 100 square feet. There were seven collections, and all of them were tastefully arranged. First honours fell to Mr. Kinghorn, Sheen Nursery, Richmond, whose group was beautifully arranged, and the plants themselves were rich in quality. A splendid *Cocos Weddelliana* gracefully occupied the centre of the group, with other Palms, *Dracenas*, *Phormiums*, *Aralias*, *Begonias*, *Crotons*, and decorative *Pelargoniums* dispersed throughout the group. The front of this group was exquisite, having as a prominent central plant *Todea superba*, and closer to the edge still a pan of *Nertera depressa*, and an outer border of *Adiantum gracillimum* relieved with small plants of *Grevillea robusta*. Messrs. Hooper & Co., Covent Garden, received the second prize. Their group was comprised of Palms, well-coloured *Crotons*, *Begonias*, *Adiantums* *farleyense*, *gracile*, and *cuneatum*, with an outer border of *Gloxinias* and *Lycopodium denticulatum*. Mr. W. Bowell, gardener to Sir H. W. Parker, Richmond, was placed third; and Mr. W. Brown, St. Mary's Nurseries, Richmond, fourth with good collections.

Fine-foliaged plants were numerous and exceedingly well exhibited, especially the collections from Mr. Bates, gardener to W. H. Punchard, Esq., Poulett Lodge, Twickenham, in the open class for nine, and Mr. Kinghorn in the class for six. The first-prize collection in the class for nine plants consisted of *Vereschaffeltia splendida*, *Alocasia metallica*, *Euterpe edulis*, *Pandanus Veitchii*, *Seaforthia elegans*, *Cycas revoluta*, *Croton Weismannii*, and a very fine plant of *Alocasia macrorrhiza variegata*. Mr. Cornhill, gardener to J. S. Virtue, Esq., Oatlands Park, was awarded the second prize in this class. For six foliage plants Mr. Kinghorn was placed first with *Stevensonia grandifolia*, *Eurya latifolia variegata*, a perfect pyramid; *Dicksonia antarctica*, *Yucca aloifolia variegata*, a very fine-coloured *Croton Weismannii* and *Pandanus Veitchii*. Mr. Bates received the second prize, and Messrs. Hooper and Co. the third; Messrs. Attrill and Crafter also exhibited well in this class.

Ferns were also remarkably good, and the first prize for eight exotics was awarded to Mr. D. East, gardener to J. Wigan, Esq., Clare Lawn, East Sheen, who exhibited *Adiantum amabile*, *Davallia Mooreana*, *Gleichenia flabellata*, *Adiantum formosum*, *Cibotium Schiedei*, *Dicksonia antarctica*, *Cyathea dealbata*, and *Alophilola excelsa*. Mr. Cornhill was placed second, and Mr. Wells, gardener to the Hon. J. C. Vivian, Selwyn Court, third. For six exotic Ferns Mr. C. Attrill, gardener to J. C. Freae, Esq., Bank Grove, Ham, was placed first; Mr. W. Smith, gardener to A. Cooper, Esq., Twickenham, second; and Mr. B. Morrell, gardener to J. S. Rutter, Esq., The Cedars, Richmond, third. Hardy Ferns were in splendid condition. Collections from Mr. James, gardener to F. Watson, Esq., Isleworth, and Mr. Crafter, gardener to the Rev. W. Finch, Woodlands, Kingston Hill, were very fine indeed. Other exhibitors of Ferns were Mr. Kinghorn and Mr. Morrell.

Stove and greenhouse plants were exhibited in the open class for nine plants by Messrs. Jackson & Sons, Kingston; Mr. Hinnell, gardener to F. Davis, Esq., Anglesea House, Surbiton; and T. V. Sutton, Esq., Gibbon Road, Kingston, who were placed in the order of their names, all exhibiting neat and well-flowered collections. In the class for six plants open only to the Richmond district, Mr. Attrill, Mr. Crafter, and Mr. Sallows, gardener to J. J. Flack, Esq., Twickenham, were first second and third respectively. Show and Fancy Pelargoniums, considering the lateness of the season, were capitally shown by Mr. James, Mr. Levesley, Spring Grove, Isleworth, and Mr. Wells, who were placed in the order of their names in the open class for Show varieties; and in the class for Fancies Mr. James received the first prize, and Mr. Wells the second. Zonals came from Mr. Crafter, Mr. Morrell, and Mr. Wells. Mr. B. E. Tipping was first for Silver-variegated Pelargoniums, Mr. Sallows second, and Mr. J. W. Wells third. For Golden-tricolor and Bronze collections the same exhibitors with the addition of Mr. Attrill shared the honours between them. *Caladiums* formed an important feature of the Show, Mr. G. Marlow taking the first place with large and well-grown examples of Mrs. Dombain, *Chantini*, Prince Albert Edward, Mrs. Henry Bull, *Splendidum*, and Max Koch; Mr. Morrell and Mr. Bowell receiving the second and third prizes. Foliage *Begonias*, *Gloxinias*, and *Lilium auratum* were well shown by Messrs. Crafter, Kinghorn, and James.

Orchids came from Messrs. Jackson & Son and Mr. Bates, who were first and second respectively in the open class for six plants, and Mr. Bates received the first prize for the special prizes offered by Messrs. Rollisson & Sons.

Mignonette was extensively exhibited, there being several special prizes for this favourite flower, Mr. Chancellor, Mr. Bates, and Mr. James receiving the greater share of the prizes.

Fuchsias, excepting the two first-prize collections, were poor, Mr. Wells receiving the first prize for nine plants, and Mr. Morrell for six. For a single specimen plant Mr. Bates won the first prize with a well-bloomed *Stephanotis floribunda*, Mr. James being placed second with *Aërides Lobbi*, and Mr. Morrell third with *Burchellia capensis*.

ROSES were very extensively exhibited by nurserymen, gardeners, and amateur growers. The quality taken collectively was fairly good, and would have been much better but from the extraordinary heat which prevailed, and which is severely felt under canvas. This caused some varieties to expand too freely and almost perish before the day had passed. For thirty-six and twenty-four varieties, distinct, three trusses of each, Messrs. Paul and Son, Cheshunt, were in their customary places, winning first honours in each class; Mr. Rumsey, Joyning's Nursery, Waltham Cross, was placed second in the latter class. For twenty-four, distinct, amateurs (open), Mr. W. Mace, gardener to Capt. Eastwick, Teddington, won the first place; and Mr. J. W. Moorman, gardener to Miss Christy, Coombe Bank, the second; and Mr. James the third in this class. For twelve blooms, distinct, Mr. James was awarded the first prize with a very uneven stand; Mr. W. Scott, the Treasurer of the National Rose Society, being placed second for a collection fully equal if not superior to the first-prize collection; and Mr. Stephenson, gardener to T. Bull, Esq., Teddington, third. In the class open to the Society's district only, Mr. James, Mr. Laing, Mr. East, and Mr. Roberts appeared to share the principal honours between them, Mr. James gaining several first prizes. An extensive display of Roses in pots was exhibited by Messrs. Veitch & Sons and Messrs. Paul & Son, which attracted considerable admiration. Messrs. Veitch & Son also contributed several boxes of cut blooms, and being only cut late on the morning of the Show remained throughout the day remarkably fresh. The same remarks apply to Messrs. Lee & Son, who sent a collection from their Ealing Nursery which both for colour and freshness we have not seen surpassed this season. A box of twenty-four *La France* were as perfect as they possibly could be and were much admired.

FRUIT.—Seventeen classes were set apart for fruit, which was generally excellent. For a collection of four dishes Mr. Edwards, gardener to J. Budgett, Esq., Ealing Park, was awarded the first prize for fine Barrington Peaches, Queen Pine Apple, black and white Grapes, and a Melon; Mr. G. Cornhill being placed second; and Mr. Fry, gardener to L. F. Baker, Esq., Haydon Hall, Eastcott, third. For black Grapes Mr. Bates was placed first with well-coloured fine fruit; Mr. Peed, Roupell Nurseries, Norwood Road, second; and Mr. C. Davis, gardener to the Rev. G. Porter, Rotherhampton, third. In the corresponding class for white Grapes Mr. Fry, Mr. Peed, and Mr. Masters, Otlands Park, were placed in the order of their names. In three other classes for Grapes Mr. Bates was to the front with well-finished examples, Mr. James taking second honours in two classes. Mr. James won the first prize for a Scarlet-fleshed Melon, and Mr. Morrell for a Green-fleshed Melon. Mr. Bates exhibited a very fine Queen Pine Apple and received the first prize. Mr. Lake, gardener to E. Ascherson, Esq., Twickenham, took the first prizes both for Peaches and Nectarines, Mr. Ramsay and Mr. Wells being placed second and third. Strawberries were very fine and were exhibited in great numbers.

VEGETABLES.—Good as the fruit was the vegetables were better, and a large display was made in the dozen or more classes set apart for their encouragement. In the collection of ten sorts Mrs. Mackinnon received the first prize, Mr. Wagstaff the second, and Mr. J. Coombes the third. The best Peas came from Mr. Marlow, Cauliflowers from Mr. Cratter, Vegetable Marrows, Cucumbers, and Onions from Mr. Morrell. The cottagers' productions were also as equally numerous and in excellent condition. There are also a number of smaller special prizes which we must omit.

The best dinner-table decoration, consisting of three vases, came from Mrs. Butcher, South Norwood, Mr. Kinghorn being placed second, and Mr. Brown third. The first prize for a single vase fell to Mrs. James Wigan, and that for the best hand bouquet to Mrs. Butcher. Mrs. Woodford, Sheen House, exhibited the three best arranged buttonholes, and Mrs. Gabriel Moran the best three vases or ornamental stands of flowers in the Society's district.

A silver medal was awarded to Mr. B. S. Williams, Holloway, for a group of new and rare plants; a silver-gilt medal to Messrs. Veitch & Son for a similar collection, and a silver medal to Messrs. Paul & Son for their collection of pot Roses. Bronze medals were awarded to Messrs. Jackson & Son, to Messrs. Osborne & Co., to Messrs. Rollisson & Sons, Mr. James Wareham, Mr. C. Turner, Messrs. Lee & Son, and Mr. Chambers.

WORK FOR THE WEEK.

FLOWER GARDEN.

THE present season has been most favourable for such plants as are generally used for carpet bedding. *Alternantheras*, *Pyrethrums*, &c., are growing freely and colouring splendidly. The lines, divisions, and groundwork where such plants are used should be kept well defined. The success of carpet bedding is due more to thorough keeping than elaboration of arrangement. Peg *Alternantheras*, pick off flowers and press close to the ground *Antennaria tomentosa*, *Cerastium*, *Pyrethrum*, *Sedums corsicum*, *glaucum*, and *lividum*. *Gnaphalium*, *Coleus*, *Iresine*, *Verbenas*, *Petunias*, *Nasturtiums*, and other plants amenable

should be pegged with a view to covering the ground as speedily as possible, as the season for the summer display is only short at best. Beds that have been mulched will require but little attention in weeding and watering, as much of that labour will be saved; but those not mulched should have the surface stirred so as to keep down weeds and keep the surface loose. Subtropical plants can hardly be overwatered provided the weather is hot. Mulch with thoroughly decayed manure, staking and tying as the plants advance in growth. *Dahlias* and *Hollyhocks* should be well attended to in staking and tying. Thin-out the shoots of *Dahlias* forming large close heads, and secure each shoot separately to the central stake by looping, avoiding bunching them. Herbaceous plants are very vigorous owing to the moist weather. Such as require it should have frequent attention in staking and tying, having regard to the height of the plants, regulating the stakes accordingly. Herbaceous *Lobelias*, *Delphiniums*, *Phloxes*, &c., should also be staked. *Pinks* and *Carnations* should be neatly staked and loosely tied before they are too far advanced. Push on their propagation by layers and pipings. The latter strike readily in sharp sandy loam in gentle bottom heat as that of a half-spent hotbed, covering with a handlight, keeping well shaded from the sun, and affording a gentle sprinkling overhead occasionally so as to keep the atmosphere moist.

Cuttings of *Roses* root freely at this time of year, selecting the ripe wood, as it will be when the flowers are shed, and inserting under handlights upon a north border. *Teas* as well as *Perpetuals* are amenable to this mode of propagation. They also strike freely in gentle bottom heat, shading from sun and keeping moist and close until growing freely, when air must be gradually admitted and the shading withdrawn by degrees. *Roses* of the *Perpetual* class as they go out of bloom should be shortened back to two or three joints, cleansing the foliage if at all infested with aphids by an application of soft soap, 2 ozs. to every gallon of water and a pint of tobacco juice, well wetting the bushes in every part, allowing it to remain a day and then wash thoroughly with the garden engine. Stir the surface lightly and give a good mulch, watering overhead and at the roots copiously in hot weather, encouraging a second growth and bloom. *Briar* and other stocks will shortly be in a sufficiently forward state for budding. Dull or moist weather is most suitable for the operation, as the bark then separates freely. Select buds on wood that has just borne flowers; they are always more mature than those obtained from gross barren shoots. Success in budding depends on selecting sound mature buds and in extracting the wood, being careful in removing the latter not to bend back the bark too sharp or bruise it in any way, as in that case it will turn black, and, of course, fail.

Clematis beds are beautiful in proportion to the attention bestowed upon them. The plants at this season have a straggling growth, and should have the shoots spread out and secured so as to keep the beds evenly furnished. When left to roam at will they are very beautiful in the wild or undressed ground, but in their natural beauty are inadmissible in dressed grounds. Climbers and other plants employed for covering walls, &c., should be frequently attended to in thinning, stopping, and nailing, tying and otherwise regulating the shoots, washing as may be required with the garden engine to cleanse the foliage of insect pests, applying if need be an insecticide. *Roses* of the *Maréchal Niel*, *Gloire de Dijon*, &c., type should have the old flowered wood cut out, and the young wood laid-in to replace it for next season's flowering. Cuttings of double yellow and double red *Wallflowers* and double *Rocket* may yet be put in. They succeed best under handlights, or will succeed upon a shady border if kept moist. Bulbs in the herbaceous border should be marked with a hard wood peg as they become ripened; any clumps which have become too large should be taken up, the border should have a liberal addition of fresh compost, be well and deeply stirred, and the best of the bulbs again planted. Those not required may be planted elsewhere, or they may be stored in sand until planting time in late summer or autumn. The bareness may be taken away by planting any reserve plants, as half-hardy annuals or spare bedding plants. Hoe and rake the borders so as to give them a neat appearance. Wage incessant war with weeds by plying the hoe and raking frequently. Constant attention should be paid to mowing, edging and rolling the walks in wet weather so as to maintain perfect neatness, upon which so much depends in rendering the general effect pleasing and satisfactory.

FRUIT HOUSES.

Melons.—There are now so many varieties of Melons that to point out any special kind as possessing particular merit were superfluous. Almost everything constituting high flavour, no matter what the variety may be, is due to the treatment to which the plants are subjected. The greatest aid to flavour is a rather dry and warm atmosphere with thorough ventilation, but this will not impart high flavour to fruit that during its period of swelling has been neglected for the want of timely removal of the superfluous growth. Liberal supplies of water up to a certain stage are as essential to a thick melting flesh as is the heat and well-ventilated atmosphere to secure high flavour. After the fruit is set and is the size of an egg the laterals should be kept pinched to

one leaf; and if this results in too much foliage, so that the leaves upon the primary shoots are crowded or shaded by them, thinning of the laterals must be resorted to, removing a little at a time. The plants should be gone over at least once, and in the case of very vigorous plants twice a week, for the removal of superfluous growths, the principal leaves being fully exposed to light and air. Until the fruit commences netting it should have every encouragement in swelling by maintaining a good moisture at the roots and sprinklings at closing time overhead. Close the house or frame at 80°, and if the temperature rise to 85° or 90° all the better, but after the fruit commences netting less atmospheric moisture should be given, a light sprinkling at closing time, maintaining thorough moisture at the roots until the fruit shows indications of ripening, when the sprinkling overhead should be discontinued and air freely admitted. If the old shoots are cut away the young ones will soon show fruit and set freely. If the plants do not show indications of a free growth, are infested with red spider, or decayed at the collar, it is better to root them out and make a fresh start. Remove the old soil entirely, and, where bottom heat is obtained from fermenting material only, a little fresh hot dung worked in will sufficiently revive the bottom heat for this time of year. Observe thorough cleanliness in houses, as the after-success depends upon the plants having a good start. Plant on hillocks rammed well down, and maintain a moist growing atmosphere. Pot off any plants requiring it and keep them sturdy. Impregnate the blossoms daily until the requisite number of fruit is set, then remove all the flowers, and earth-up the plants. Look well after canker at the collar of the plants, as it spreads rapidly; it is overcome by rubbing the infected parts with quicklime. Shade only to prevent flagging. Take care to cut the fruits with a considerable portion of stem when removing them before quite ripe in order to prolong the season of supply.

Cucumbers.—This is a good time to sow for raising plants for early autumn fruiting, good plants for planting out being had in about a month. Liberal attention and treatment must be given to plants in full bearing, thinning-out the exhausted growths and foliage, laying-in young bearing wood and earthing-up the plants at short intervals. Apply liquid manure copiously, and maintain an abundance of atmospheric moisture, particularly in hot weather. Be careful not to overcrop young plants; do not allow the fruit to hang too long upon the vines. Syringe well at closing time, about 4 P.M. No fire heat will now be necessary, but when making new beds a gentle bottom heat is essential to a good start. Dust the plants with sulphur about once a week, and if aphids appear fumigate gently. If worms are troublesome water with weak lime water.

PLANT HOUSES.

Stove.—*Jasminum Sambac flore-pleno* has pure white flowers about the size of a Daisy, which are very fragrant and most useful for cutting. It is easily grown from cuttings taken off with a heel inserted in half loam and sand and placed in bottom heat. When rooted pot into 3-inch pots and continue them in bottom heat until well established, pinching out the points of the shoots to induce them to break near the base of the plant; train horizontally so as to induce well-furnished plants, shift into larger pots, and ultimately train to a trellis for flowering. Turfy loam with a fourth of well-decayed manure or leaf soil and a free admixture of sand will grow it well. Keep the plants well syringed, as they are subject to red spider. *Æchmea discolor* and *Æ. miniata* are useful for summer and autumn decoration, and should be grown in quantity—single crowns in 7-inch pots. Turfy loam or peat will grow them, with a free admixture of sand and a few nodules of charcoal, and crocks broken rather small to keep the soil open and sweet, good drainage being provided, as free watering is required, the plants being epiphytal in their native habitats. They should be grown near the light upon a shelf or where they can have plenty of light, and then they throw up their flowers strongly, remaining in good condition for six weeks. *Tillandsia Lindenii* is very beautiful, having narrow, channelled, gracefully curved leaves, which are longer than most of the genus. Its blue flowers produced in succession from its lengthened scapes have a grand effect. It is of easy culture, succeeding under ordinary stove treatment. The earliest-flowered *Ixoras* will push strongly if now placed in brisk heat and humid atmosphere, and will flower again in autumn, being then very useful for cutting; afford weak liquid manure once a week if the pots are full of roots. *I. aurantiaca* and *I. coccinea* are two of the best for this purpose. The second batch of *Euphorbia* and *Poinsettia* cuttings will by this time be rooted and should be moved into larger pots, as from their free-rooting nature they become stunted in growth if the roots are confined in small pots whilst the plants are young. Cuttings of most hardwooded plants will now be in a half-ripened state and will root freely, especially if they have the advantage of bottom heat and are kept close. They should be inserted singly in small pots, as they may be transferred to larger without receiving any check, growing them on through the winter, they then being considerably advanced. Plants that may be so increased now are *Combretum purpureum*, *Clerodendrons Balfourianum*, *splendens*, and others of the climbing section, as well as the shrubby, such as

fallax, *fragrans*, and *Kämpferi*, likewise *Bougainvilleas*, *Dipladenias*, *Æschynanthuses*, *Gardenias*, *Hexacentris mysorensis*, *Ixoras*, *Medinillas*, *Stephanotis*, *Rondeletias*, *Tabernaemontanas*, *Thunbergias*, and *Meyenias*. Choice varieties of *Gloxinias* should be increased by leaf-cuttings; they strike much more surely now than earlier in the season, when the leaves are liable to damp off. They should be shaded from bright sun and kept rather close.

Young plants of *Stephanotis floribunda* being forwarded for next year's flowering should have the shoots trained near the glass in all the light possible with free ventilation, so as to induce firm growth. Young plants of *Clerodendron Balfourianum* should be continued in heat after flowering so as to encourage growth, training the shoots near the glass; if they require more pot room shift at once into larger pots. Turfy yellow loam with a fourth of well-decayed manure and a free admixture of sand is a suitable compost. See that *Palms* and *Dracenas* do not suffer from attacks of red spider and by want of water at the roots. Syringing the under side of the leaves will free them of red spider. *Gesneras Cooperi*, *Donckelaari*, and others of that type may be increased from cuttings, the flower stems being cut down to a couple of inches above the bulb. Young growths will proceed from the crown, and these when 2 inches in length should be inserted singly in small pots in equal parts of sand and loam, having water only to keep from flagging. After rooting encourage all the growth possible.

Insects at this time of year increase rapidly. Constant attention must be paid to fumigation against thrips and aphids, syringing against mealy bug and red spider, and sponging for the clearance of scale, otherwise the plants will soon become seriously disfigured and many permanently injured. Dull weather should be chosen for this, for it is then much more comfortably done than when the days are bright and sunny. To keep men at such work in hot stoves in bright hot weather is indicative of bad management and thoughtlessness. Advantage should be taken of wet days to push forward the cleaning of plants, it being false economy to keep men working in the rain when there is pressing work on hand under glass.

TO CORRESPONDENTS.

* * All correspondence should be directed either to "The Editors," or to "The Publisher." Letters addressed to Mr. Johnson or Dr. Hogg often remain unopened unavoidably. We request that no one will write privately to any of our correspondents, as doing so subjects them to unjustifiable trouble and expense. Correspondents should not mix up on the same sheet questions relating to Gardening and those on Poultry and Bee subjects, and should never send more than two or three questions at once. All articles intended for insertion should be written on one side of the paper only. We cannot reply to questions through the post.

BOOKS (*W. T. Ward*).—On the methods of collecting and preserving insects, Green's "Insect Hunter's Companion," 1s. 6d. (Van Voorst), may be recommended. Mr. Merrin's "Lepidopterist's Calendar," 3s. 6d. (Newman), contains much valuable information about the times of appearance of butterflies and moths. As first books on these interesting insects, "British Butterflies," 1s., and "Common British Moths," 1s. (Routledge), are good. If a general glance at the whole class be desired, the Rev. W. Haughton's "Sketches of British Insects," 3s. 6d. (Groombridge), is a useful introduction, or Figuier's "Insect World," 5s. 6d. (Cassell).

GUANO WATER (*W. S.*).—A quarter of an ounce of guano to each gallon of water for potted plants, and half an ounce to each gallon for plants in beds.

ALYSSUM WIERZBICKII SEEDS (*H. S.*).—We cannot aid you. Write to Messrs. Rollison, you will have a polite reply.

STRAWBERRY (*H. D.*).—The Strawberry is a fruit.

NEIGHBOUR'S TREES (*E. W. M.*).—Unless we saw the place, and had full knowledge of the tenancy, its priority, &c., we could not venture to give an opinion.

PEACH LEAVES DISEASED (*Y. C. S.*).—They are attacked by spot. Deficient root-action is the cause. Apply copiously tepid very weak manure water.

FUNGUS ON ROSES (*Mrs. A. G.*).—See our answer on page 471 of the previous volume.

GRAPES DISEASED (*W. M. and K. M.*).—They are very severely spotted. The roots are inactive, and require tepid liquid manure. We cannot name plants from such fragments as "W. M." enclosed.

ANTS ON MUSHROOM BED (*Clifford*).—We know of no mode of excluding them unless you can sprinkle Scotch snuff over the surface.

VINE LEAVES DISEASED (*T. White*).—Water the Vines with very weak liquid manure, and give more shade and better ventilation.

GRAPE STALKS DECAYED (*W. J. C.*).—They are shanked, and it is caused by defective root-action. Apply liquid manure to the roots.

SAVING SEED OF PRIMULA SINENSIS (*C. T. H.*).—Select sturdy plants in somewhat small pots, with a truss of fine flowers fully developed, and place them on a shelf near the glass, where they have plenty of light and air. In watering take care not to wet the blossom, and in due course you will obtain a few seed pods from each plant, affording a little seed, so little that in order to obtain a large supply some dozens of plants must be reserved for the purpose. It is very advantageous to fertilise the flowers, using a camel's-hair brush.

GRAPES NOT COLOURING (*W. H. H.*).—Your Grapes are good, and would have coloured well if the Vines had not been overcropped. The plants will

not injure the Grapes, and you would do harm rather than good by applying whitewash to the glass. The temperatures are right. Give all the ventilation possible subject to the day and night heat being maintained at the figures submitted. Apply liberally tepid liquid manure to the roots, either soot water, guano water, sewage, or the drainage from dunghills, and your Grapes will probably improve considerably.

PEACHES AND NECTARINES DROPPING (*A Cheltenham Gardener*).—The evil is no doubt attributable to the trees having been so greatly neglected last year. According to your statement a great portion of the young roots must have been destroyed, and now that the swelling fruit requires support the roots are inadequate for affording the necessary supply. By laying-in young wood thinly, keeping the foliage clean, and procuring healthy root-action your trees may regain their lost vigour and bear well another year. That is the most that you can hope for under the circumstances.

TORENTIA FOURNIERI (*J. T. Brixton*).—You have been rightly informed. This plant is an annual, and a very beautiful one for greenhouse and conservatory decoration in the summer. The seed if sown in spring produces attractive flowering plants the same season. We have had no experience with sowing it in the autumn, but the experiment is worth trying so as to have flowering plants as early as possible in the spring and early summer months.

THRIPS ON VINES (*Vexed*).—Fumigate them at once for two or three nights successively. The smoke will not affect the flavour of the Grapes that are just showing signs of colouring. See notes on Vine insects in another column.

MELONS FOR AUTUMN (*G. B.*).—Strong plants planted now and a little bottom heat provided by fermenting manure will with good attention produce ripe fruit towards the end of September. Little Heath is one of the most hardy, and Victory of Bath is a free-setting and excellent variety.

PELARGONIUM FLOWERS DROPPING (*H. T. F.*).—A little ordinary gum dissolved in water and a drop placed at the base of the petals will prevent them dropping during the transit of the flowers. The flowers should be tied in rather close bunches, which should be enclosed in tissue paper, and be further securely packed with wadding. Only a very little of the gum must be applied with a small brush.

RAISING PERENNIAL FLOWERS (*Robert*).—Sow the seed at once in shallow drills in an open border, covering it very slightly with fine soil. A few plants suitable for your purpose are Wallflowers, Sweet Williams, Canterbury Bells, Delphinium formosum, Scabious, Antirrhinum, and Brompton and East Lothian Stocks. As soon as the plants are large enough to be handled they may be transplanted a few inches apart in nursery beds, and in October they may be removed to their flowering quarters.

NAMES OF PLANTS (*O. H. C.*).—*Gongora atro-purpurea*, and apparently *Maxillaria tetragona*. (*John Clyde*).—We cannot name plants from mere leaves.

THE HOME FARM:

POULTRY, PIGEON, AND BEE CHRONICLE.

MAKING PASTURE AND MEADOW HAY.

THE making of meadow and pasture hay must be considered as a very different matter from that of making field hay; and although the machinery in use is the same as used for cutting and making field hay, yet upon irrigated meadows and others with wide open trenches the mowing machine is not always available. It is the same to some extent in the park pastures sometimes where there are a number of ornamental trees, for although where the ground is level a considerable portion of the grass may be cut with the mower, yet under the trees the grass is usually cut with the scythe, and particularly when the trees are elms. These are sure to have a number of runner roots, which throw up small twigs for a considerable distance around the trees. Some of them have very hard stems, which would be liable to break the knives of the mowing machine or disarrange the working parts of the implement. It is therefore safer to use the scythe in such cases. In order that dry pasture land and meadows should be in good order for cutting the grass with the mowing machine the ground should be looked over in early spring and all stones picked up and removed; and in the case of park lands with timber about it should be looked over in the month of April, for the winds peculiar to the month of March will be sure to scatter over the pasture more or less the dead broken branches from the ornamental timber. In some of the moist meadows requiring open trenches to lay them dry it is best to pipe-drain the trenches and fill-in level with the surface. The grass may then be cut with the machine; whereas without this advantage the crop must be cut with the scythe, which in districts where labourers are scarce is very expensive.

In order that the meadows should have the full advantage of the season they should be laid up and neither fed by cattle or sheep after the 1st of February, and as soon after as convenient they should be rolled with a heavy iron roller. In some meadows,

even after pipe-draining, there will still remain patches which produce the small rushes, and as these always start in growth before the sweet grasses they should be cut over with the scythe in the month of April, which will not only prevent the rushes from overpowering the best grasses, but it will effectually keep down the coarser grasses, which may be cut with the rushes, and thus improve the general quality of the hay. The time at which grass should be cut, as regards the quality of the hay and other matters, is of considerable importance. For instance, on much of the park land and dry pastures of a dry season it should be particularly noticed whether the finer and bottom grasses are growing, and if not the sooner the grass is cut the better. On the contrary, if the season is showery and the ground moist, although the forwardst grasses may be in bloom, yet the bottom and fine grass will continue to grow and make up a heavy crop, in which case the cutting may be deferred until the Dutch, the suckling, the bird's-foot trefoil or yellow-blossomed, the broom grass, and others are in flower. There can be no question that the colour of the hay and the aroma is a tolerable guide to quality, but this is often carried too far and accepted as the only criterion of value, for the "sweet-scented vernal grass" which contributes to nearly all pasture hay the fragrant aroma is often found on the poorest of grass lands. This is the cause of much of the hay sold in the metropolitan and other markets being of but little feeding value, although sold at a high price by reason of its bright green colour and sweet scent.

The time for cutting grass in the water meadows is different altogether, for where there is a full crop, whether the grasses are in bloom or not, it should be cut. If allowed to remain too long the grass becomes laid or lodged, and that next the ground the leaves of the grass become partially decayed, which not only damages the quality of hay, but increases the cost of cutting, and delays and deteriorates the succeeding crop. As before stated, wherever the mowing machine can be used on pastures or meadows it should be adopted, not only because it saves the labour of many men as compared with the scythe, but also because it is highly desirable that all the grass intended to make up one rick of hay should be cut as nearly as possible at the same time, so that all should be ready for carting together, and the rick finished and topped to prevent exposure to the weather. After cutting the grass the chief point, as regards making the hay, is to take into consideration the bulk of the crop and the character of the season. If the crop is light and the weather dry upon the upland and park pastures it often requires little or no labour beyond cutting, raking in, and carting. We have on various occasions cut the grass before nine o'clock in the morning, and got it into rick as well-made hay in the evening. Although this is quite exceptional it goes to show that the grass in a dry time may not be tedded several times, but the swathe only turned, and on the second or third day, according to the bulk of the crop, may be carried to the stack. This plan, however, chiefly applies to dry pastures and when the hay is required for consumption on the home farm, because in case it is required for sale more care must be taken to preserve the colour, as colour means quality in the eyes of the hay dealer. Therefore in low-lying meadows subject to night fogs the hay should always after being tedded be made into small pooks, called grasscocks, for the night, and then spread again into rows in the morning, and if sufficiently made be got into larger rows just before the waggon, as it is best to be taken up hot out of the row.

Let us now consider the question of treatment of the grass for hay when by the state of the barometer and the general character of the season we may feel assured that showery and difficult hay-making weather will prevail. In that case, instead of tedding, it will be well to only turn the swathe on the second day after cutting; on the third day to get the hay into small pooks, and then make two or three pooks into one on the day following, in which case the hay will have retained its colour. But we must still be extremely jealous of the weather, and throw open the large pooks to get them dry for carting, but only in the promise of a

fine drying day, and the probability of stacking the hay the same or following day. If the latter the hay must again be poked for the night. In the water meadows or on rich alluvial soils it is common to cut the aftergrowth for hay, in the making of which it is oftentimes best not to ted the grass, but simply make it into grasscocks, and turn them as occasion may require. But we must remember that in the short days of autumn that we cannot expect the hay to dry quickly, therefore to keep the hay in small cocks and give it time is best. It will be gradually making without risk, the cocks being only turned over occasionally; the colour of the hay will then be preserved. We knew last autumn hay made in this way so late in the season that the white hoar frost in the mornings was observed on the top of the pooks, yet this hay was eventually got to stack in fair condition for consumption of stock on the home farm.

In making the stand or staddle for the ricks it is of importance that the size of the stand should be adapted to the quantity of hay to be stacked, and we allow as a general rule that for 20 tons of hay the stand should be 13 feet wide and 30 feet long. There is practically a great objection to the stand being made too large or too small for the quantity of hay, and to have the full advantage of a proper adjustment the size may be easily altered according to the measurement we have laid down for 20 tons in a rick. Many of the statements made in our article upon field hay will equally apply to the making ricks of pasture hay. For the improvement of hay our remarks relating to spicing will apply with still more force in the case of meadow or pasture hay, for it will not only improve hay injured by rain as stated in reference to field hay, but in the case of water meadow hay partially injured through the excess of crop and the decay of the grass at bottom it will improve and give the hay a pleasant and grateful flavour, and induce the cattle to eat it, which, under ordinary circumstances, they would scarcely eat with any advantage. This matter of spicing also applies with benefit to the hay made from the poor and coarse grasses, the produce of poor and mossy pastures. For this purpose the following mixture is recommended:—Fenugreek in powder, 112 lbs.; pimento, 4 lbs.; aniseed, 4 lbs.; caraway, 4 lbs.; cumin, 2 lbs. The quantity to use for a ton of hay of the spice materials is from 2½ to 3 lbs.; the cost is 10d. per pound.

WORK ON THE HOME FARM.

Horse Labour.—As fast as the hay is fit for carting the horses will now be almost daily employed in carrying it to the rick. When the weather is fine it is well at such a busy period to do the cultivation for turnips, &c., in the mornings and carry hay in the afternoon, as it is always in better condition in the afternoon, particularly in hot still weather, the dews being often so heavy in the mornings. It is well also to be entirely prepared for stacking the hay as soon as ready by having the materials, such as faggots, &c., at hand for making the rick stands. Horse-hoeing will now be required for the mangold, early cabbages, carrots, kohlrabi, &c., and also the Swedish turnips where sown early. In the case of wet weather following immediately after the horse-hoeing, the couch grass and any weeds which may be likely to strike again should be picked up by the women.

Hand Labour.—The mangold crop and early Swedes may now be set out, and it is very important that the strongest plants should be left in preference to leaving them at any exact distance apart in the rows. The very fact of the strongest plants being exhibited shows that they have, in preference to the weaker ones, got hold of the manure, and in consequence will go on to maturity with the greater probability of becoming the largest roots, and better able also to withstand any attack from enemies such as the brown grub, &c. The hoeing of carrots should now be persevered with in order to keep the land perfectly clean, and if they are set out in the rows let it be done with a small 4-inch hoe. We prefer to clean the rows and let the plants remain yet awhile; and when the roots are about the size of the finger they may be hand-pulled for cattle, pigs, &c., as upon certain occasions we have pulled as much as ten to twelve tons per acre, and removed daily for feeding purposes. This not only preserves a sufficient number of plants to insure them against their only enemy the grub, but in the act of pulling it opens the soil and allows the remaining plants to swell with great ease. In this manner we have pulled fourteen tons to the acre for immediate use, and the main crop has produced from twenty-five to thirty tons per acre according to the season. As soon as any deficiency of plants is discovered in the mangold crop it is advisable to plant out, to fill up vacancies, some good strong cabbage plants of the Champion Cattle cabbage variety, these being the best for the purpose, as fewer plants will be required, the heads coming so large. Although the weather may be dry and the ground hard, yet they are bound to live and grow if they are set with the spade, as it opens the land so that the plants, although they may be long and strong, are introduced into the moist ground, so essential to their taking root, and if the heart of the plant is buried about an inch so much the better in very hot weather.

The work of cutting the hogweed and coarse grass on the borders of the fields is still continued, and where cut first the second cutting is now ready. Our store pigs which are now

receiving this kind of green food are doing remarkably well. In addition to the border grass they get a small quantity of broken and soaked Indian corn, with barley meal mixed so as to form a pudding. Where the farm buildings are usually coated with tar or paint this is the best time for doing the work, and we are now using coal tar from the gasworks for the purpose; and we find that cheap boarding, such as that cut from fir trees or elm, will last a great many years when it is kept tarred at the proper season, it being necessary that the wood should be perfectly dry before either paint or tar is used. The herdsman or dairyman should now be alive to the advantage in summer time of taking the dairy cows from the shaded pastures to their stalls when the sun is in full power. If left to the shade of trees only they still suffer from the annoyance of flies, and leave their manure also where it does no good. When, however, the animals are driven to their pens from about eleven o'clock till four o'clock in the afternoon they will be free from flies, and if they get a bait of green fodder in the middle of the day so much the better. They will not only give more milk, but will give it down more kindly, when they lead a quiet life in the stalls free from the irritation of flies. The heifers on the home farm that may now be from eighteen months to two years of age should be put to the bull in July and August, as they will then come to calve at a favourable time of year—that is, about the end of April or the early part of May, with a prospect of plenty of grass before them.

ROYAL COUNTIES SHOW.

TRULY a thing of progress. But a few years since it was open on one day for a few hours at Basingstoke, now it takes four days. A small field sufficed to hold everything connected with it, now it covers 22 acres, and in every way reminds one of the Royal Agricultural Society of England. It moves about from town to town in the two counties—favoured Hants and Berks, containing the residences of our Sovereign.

The spot where the Show was held this year was well chosen. It would be difficult to find a more beautiful locality than Southampton Common. Not a common in the ordinary sense of the word; not land with "barren" written on the face of it, and bearing for its crop a scanty and stunted portion of heath, but boasting of oaks that have been centuries attaining their present size, and of underwood 6 or 7 feet high, growing in patches and affording shelter both for man and beast. It is the sort of spot where from facility of concealment Prince Hal might have chased Falstaff, or where in earlier days, spite of its contiguity to a considerable town, a strong body of traders ere they left the open would conceal money and valuables, and perhaps calculate and organise means of defence before they entered the wood. We are happy to live in quieter days, when the glades, solitudes, and thickets may be put to quieter and more peaceful pursuits. It is said by a poet—

"Our groves were planted to conceal at noon
The pensive wanderer beneath their shades."

The very mention of shade is refreshing. If there were ever weather when we would run into water or under trees to find shelter from the sun (thermometer at 90° in the shade), it was on the days of this enjoyable Show. The common was a beautiful sight: the dusty road was deserted for the green sward, and little knots of well and gaily dressed people were now seen, now hidden, as they passed among the thickets, and, although out of sight, could be traced by the ringing laughter that was heard. The roadside inn was dressed-out, and the outer accommodation was such that we should almost call it the English Teniers, or wish that Wilkie were still among us to hand down to the future a representation of one of our agricultural outings, and dispel the idea so common in other countries that an Englishman takes his pleasure sadly. We have a great respect for the roadside inns. They have an air of comfort not to be found in modern and more pretentious buildings dignified by the name of hotels. The old roadside inn was a home to the wayfarer who stopped there. We saw such an one covering much ground; when it was built land was not sold by the foot. A good, large, wide entrance; a large bow window on each side; seats in front of the house; a settle round a patriarchal tree, and all crowded. Booths had established themselves, shows made a great display, and here and there a brown gipsy promised all things to all people. Clever people! they offer that which all want, but do not at once give all. There remains yet something better behind, but "she should lose her gift if she told it for anything but silver," and so one of the few sixpences see the light to purchase the knowledge "that she will on that day see a dark man, and the planets assure her that though hot-tempered he will make a very good husband." This, however, is outside, and our principal work lies within; but yet these are accessories, and some who have seen many and foreign climes may dwell on such a scene as was here, and find it would not suffer by comparison with foreign fêtes. We cannot dwell longer among our rural scenery and its inhabitants, but it will be long before we forget it. Our first feeling after we had entered the Show-yard gates was one of surprise at the growing dimensions

of the Show, and next admiration of the spot chosen to hold it. Standing close to the orchestra and looking towards the sea it was a sight of marvellous beauty.

The poultry Show was a long stride in advance and very superior to any we have before seen. As should be at an agricultural meeting *Dorkings* headed the list, inviting competitors for six prizes. There was, perhaps, less improvement in this class than in some others, but the fact is easily explained. Hampshire is become the home of some of the best *Dorkings* that are bred—birds that are “to the fore” in almost every prize sheet. We have no hesitation in saying the winners here would have had the same position anywhere. The two classes of *Cochins* were well filled with good birds, and well-known names will be seen among the distinguished. We thought there were birds of unusual merit in the Buffs and White. The Dark *Brahmas* were well represented, and the prize birds were very large and heavy. They were more numerous and more meritorious than their Light brethren. The exaggeration of the vulture hock in some instances would almost justify us in believing some amateurs seek to develop it as a principal beauty of these breeds. No breed showed more progress than the *Spanish*. Several of the pens were perfect. For many years *Hamburghs* were weak, and Pencilled and Spangled were shown in the same class; they were now divided and the entries improved in numbers and quality in consequence. There were good specimens in all the classes. The *Houdans* and *Crève Cœur*s were excellent. They proved here as elsewhere that the foreign breeds introduced into this country soon become better than their imported originals. They not only increase in size but in all points. There was a class of *Langshans*, some fine fowls among them, especially the first-prize pen. *Polands* are always weak, and this time was not an exception. Prizes were withheld, but the Judge was empowered in any such case to add those not awarded to other entries of great merit. The classes for *Bantams* were hard to judge; good specimens were common and entries were numerous. Some Black-breasted Reds were perfect, and some of the Blacks were faultless. The Variety class brought together the different breeds—Black *Hamburghs*, *Malays*, *Andalusians*, &c. Little could be said for *Rouen* and *Aylesbury Ducks*; they produced neither numbers nor quality. The Varieties showed some of the best *Buenos Ayrean* we ever saw, and also some very tame *Widgeon*.

It causes us to repeat that which we have often written—that as soon as all are agreed upon the points of any particular breed it is sure to be produced. There is great difference of opinion about vulture hocks, and in some specimens it is developed to an extent that borders on the ridiculous, the hocks almost touching the ground. It is a pity it cannot be decided whether the original *Cochin* is the bird to breed or the modern introduction. In the *Spanish* it was said the comb of the cock should be upright, and it is so. What would be thought of a new school that demanded lopping combs in *Spanish* cocks? There were very good entries of very good Game, but here again there was a novelty, several pens were shown undubbed. We confess they do not look like Game, and show to a great disadvantage against their trimmed competitors. Those who know this breed best know that they will fight, and also know that if they must fight it is a mercy to cut off comb and gills. As to the suffering of the operation, when these parts are removed they are given in small pieces to the patient, who always eats them. The birds shown were very good, but some of them are certainly too stilty. The quality of the *Geese* and *Turkeys* was excellent, but they were deficient in numbers.

The *Pigeons* alone would have formed a good show. The Carriers, *Jacobins*, *Fantails*, *Dragoons*, and *Magpies* were especially good. *Antwerps* were meritorious. No less than sixteen of the birds exhibited in Any other variety class figure in the prize sheet. The homing *Pigeons* brought twenty-five competing pens, and these again claimed sixteen notices at the Judge's hands.

Rabbits closed the Show. The long-eared measured between 18 and 20 inches. The Silver-Greys were very good in coat, and the Hare *Rabbits* were marvellously like Hares in appearance and habit.

Mr. Bailly was Judge.

DONCASTER POULTRY SHOW.

The annual Show was held at Doncaster, on the Racecourse, on the 26th, 27th, and 28th ult. The weather was excessively hot, and the number of visitors very large on all the days. Fortunately the poultry, &c., were shown under a permanent shed, where they were much cooler than if they had been under canvas, and yet one celebrated *La Flèche* hen closed her career in consequence of the heat. The pens were well arranged, and ample space was afforded for the visitors. The entries were about fifty more than those of last year, and the quality was far ahead of that of any previous year.

Game headed the list. Black Red cocks were very poor with the exception of the winners. The first, a grand all-round bird, could scarcely show in a compact form on account of the heat; second a fair bird; and third very good but small and late-bred. Hens of that colour poor except the winners. Brown Red cocks were the best class of Game. The first a beautifully marked stag, excellent in style and fine in form; second not equal in colour and marking but full, better in chest and shoulder, and good in all Game properties; the third was sadly out of order and showed badly, being flat and long in hock and not at all in show form, though said to be the cup bird at Thorne. Hens very good, throughout but somewhat out of feather. Duckwing cocks first a grand coloured bird, firm and good in style; second a nice colour but very soft. Hens of that variety also good, the first one of rare quality and the next in points to the cup-winner. Pile cocks, first a smart bird well shown; second rather heavy feathered; third a fair bird. Hens were a smart lot in all respects except feather, and many were in need of a moult. *Dorkings* were very good in both classes; and *Spanish* about the best class in the Show, although some of the best were a little coarse. *Cochins*, first and third were Buffs, and second Partridge. *Brahmas* were both good classes, and for the time of year in good feather. *Hamburghs* were mixed classes. In Silvers, first was a grand all-round pen of Spangles; the second also of that variety; and third Pencils. In Golden also Spangles were first, and Pencils second and third. *Polish*, first and second Golden, and third the recent importation—viz., Buffs, or more properly Buff-laced; the hen a grand one, but the cock failing in crest. The cup for this section was awarded to a pen of Black *Hamburghs*, the cock, perhaps, about the best we have yet seen; second also a grand pen of that breed; and third *La Flèche*. There was one class for chickens; first was a fine well-grown set of Light *Brahmas*; second Dark *Brahmas*. *Bantams* were the largest classes of all and mostly in good feather, the cup being awarded to a small pair of Black Reds. In the Variety class Blacks were very good and in the best of feather.

Geese and *Ducks* were large and good, but mostly out of feather with the exception of the *Bahamas* and *Chilian Teal* in the Variety class.

Pigeons through some unfortunate mistake were in pairs, and the entry was in consequence rather small, but there were some good specimens in all classes.

POULTRY.—GAME.—Black-breasted.—Cock.—1, C. W. Brierley. 2, T. Woods. 3, Dr. Cameron. *Hen.*—1, Dr. Cameron. 2, Sales & Bentley. 3, T. Baker. *Brown Red.—Cock.*—Cup and 1, C. W. Brierley. 2, W. Darby. **SELLING CLASS.**—1, A. Travis. 2, J. E. Crofts.

JUDGE.—Mr. E. Hutton.

RABBIT REARING.

As soon as the young are five or six weeks old the question of separating them from the doe should be considered. Many fanciers young and inexperienced buy a couple of Rabbits for breeding, and

then when the litter has overpowered the mother and it has become absolutely necessary to provide some fresh home for the new comers, the question is hurriedly considered, and a box or tub, alike unsuitable, is selected; hence many die from being trampled on or from dirt and suffocation.

As to the age at which the young Rabbits may with safety be removed much depends upon the constitution and stamp of the breed. We may remark that five weeks is the lowest and eight the highest age at which the young should be removed. If taken too soon they will not have a chance of being strong, but if left too long the mother suffers considerably. Very often she turns upon the young, like a Swan upon its cygnets, when they arrive at what she considers a sufficiently advanced age to exist without a continuance of her maternal care.

The hutch for young Rabbits should be roomy and large, special attention being paid to ventilation. For a couple of litters, say ten or twelve young ones, a hutch 4 feet long, 2 feet deep, and 15 inches high, is requisite. The wood forming the sides, back, top, and bottom should be at least three-quarters of an inch in thickness, and should be of a hard impenetrable nature. Deal will do very well if well seasoned. The joints should be carefully dove-tailed, and care taken to avoid anything likely to cause a draught. At the back of the bottom piece cut a slab about an inch wide from the whole length of the hutch. Through this a considerable quantity of waste will escape, and the Rabbits' play will tend to drive the refuse towards the back if the hutch be slightly sloped. To accomplish this the hutch should be placed on a sloped bench, or the front should be raised by means of a board or bar placed along the whole length. In either case the front should be not more than 3 inches higher than the back. If the hutch is 2 feet deep this elevation will do very well, but if less the propping should be diminished. If the slope is too great the little inmates will be unable to obtain a footing. Never let a hutch slope from the front. The great objection to this is that the Rabbits naturally look in the direction of the light, and by standing constantly on a slope the blood rushes to their heads, causing several complaints. No sleeping place is required. In place of it a piece of wood the length of the depth of the hutch and about 4 inches high should be fixed about 15 inches from one end. This will keep the straw or hay in one place and prevent its being trampled on. A small rack for green stuff may be useful. It has a great drawback, because the young ones sometimes jump up against it in play and damage themselves severely. The front should be made to open about half the size of the whole, the door being nearly in the centre. A hoe can then easily be inserted to clean out the whole. If the hutch is kept indoors the whole of the front may with safety be left open, but if any doubt is entertained as to the temperature the part enclosed for the bedding may be boarded up.

The young ones should all be about the same age or the younger will suffer. As regards food, the directions given in a previous paper on feeding may be taken as a good guide with a few slight variations. The oats should not be given whole, as they are hard for the young teeth; they should therefore be either bruised or soaked, and a little meal is good. Bread is good occasionally; if very stale it may be given dry, but if not it should be soaked and then dried as nearly as possible. Pieces of carrots and turnips may be thrown into them. In green stuffs select those kinds not too damp, and let all the food of this description be carefully dried before being given. Cabbage and lettuces are both too succulent for young Rabbits, and should be avoided. Drier kinds, such as young corn, grass, and cabbage and lettuce stalks, will be better. If the weather is very hot this rule must not be very strictly attended to, and a little lettuce may be given; cabbages may also be given, but not too freely, except when well dried.

Lop Rabbits are generally kept with their mothers longer than usual. Sometimes when the numbers have been reduced greatly by aid of nurse does the remnant are kept with their mothers till they are eight or ten weeks old. This is certainly a great strain on the parent; but when the litters only number one or two does not do much harm. Dutch young ones are often removed much earlier because they are not wished to grow large, and there are often so many that were they left more than five or six weeks they would tear the mother down very much. In the very large species the young may be removed at six weeks. In the other varieties from six to eight weeks, according to the number and strength of the litter, may be mentioned as the best age for removal.—GETA.

THE RAINFALL IN HAMPSHIRE.

THE heavy rainfall which we have had during the month of May, amounting in this locality to upwards of 5 inches, has induced me to look back on my previous records and to note several somewhat singular circumstances that it may perhaps be interesting to point out. These 5 inches are not only more than double the usual average of the month, but the heaviest fall we have had in this month for more than thirty years. Although during this period there has been a quantity of timber removed, and the district has become more open, yet the rainfall, instead of being less has been more, contrary to the usual

opinion. Thus, during the first ten of these thirty years, the average monthly rainfall was 2.719, or nearly 27.2 inches per annum. During the succeeding ten years it was 28.6 for the year, or 2.86 for the monthly falls; whilst during the last ten years the annual fall has been 32.33, or monthly average of 3.32 inches; thus each decade has become wetter than the previous one, which is altogether opposed to the doctrine that as the country is cleared it becomes drier. The driest year by far during the last twenty years was the first—viz., 1858, the next 1870, then 1864 and 1873; whilst the wettest during this period was 1872, followed by 1877, 1868, and 1875. This accounts for the probable fact that the natural yield of wheat has diminished during each decade, and has needed as well as received the artificial aid that is now frequently applied. The annual fall of rain from January to December inclusive, as usually recorded, bears but a moderate relation to the growth and yield of wheat; for the agricultural year actually begins and ends with September, and the fall of rain in the last three months of the year forms a very important factor in the yield of wheat in the succeeding year. Thus, for example, in the year 1872, reckoning from January to December, we had a fall of 43.97, but from the preceding October to the end of September it was only 34.45. In 1877 the usual reckoning gave 35.77, whilst to the end of September it amounted in the preceding twelve months to 31.10. The driest month on the average for twenty years has been April, and then May and February; the wettest January, and next October and September. In the previous ten years February was the driest and October the wettest.—W. C. SPOONER, *Eling, Southampton.*

VARIETIES.

WE regret to hear that serious irregularities occurred at the public auction of poultry at the end of the Paris Show. English birds were put up and knocked down for a few francs on which their owners wished reserved prices to be placed. Some of Mrs. Christy's Buff Cochins, which we so much admired, were thrown away in this manner.

THE poultry Show of the Staffordshire Agricultural Society will be held at Leek on September 18th and 19th, and entries can be made with the Secretary at Newcastle, Staffordshire, up to the 31st of August, from whom, on application, prize lists and certificates of entry can be obtained. The birds, with the exception of the Turkeys, Geese, Ducks, and fowls entered in the selling classes, must all be chickens of this year. First and second prizes of £2 and £1, and in some classes three prizes, are offered, with nine silver cups value £3 3s. each, for the best bird or birds entered in the classes for Game, Spanish, Dorkings, Cochins, Brahmas, Hamburgs, Houdans, Crève-Cœur, Polish, Leghorns, Turkeys, Geese, Ducks, and Bantams. The poultry will be under cover, and carefully attended to and fed.

THE *Country Brewers' Gazette* observes that although there are only about 72,000 acres of hop land in the United Kingdom, the capital involved in its cultivation amounts nearly to half a million of money, and the annual value of the produce, taking an average of thirty years past, has been quite £3,000,000. Numbers of labourers find remunerative employment in the hop-producing districts all the year round, and swarms of emigrants flock down from the smoke of London and other large towns for the picking season to gain health and money. It is calculated that at least 90,000 immigrants come into Kent and Sussex every year for the hopping; and many persons migrate from the towns in the Black Country to the pleasant hop yards of Worcestershire and Herefordshire. Moreover, hops have a special quarter allotted to them in London, in the Borough, where the hop trade has been carried on from time immemorial. The numerous stately hop warehouses, the streets devoted to the offices of hop merchants and factors, the hum and bustle of business in the season, all indicate that the cultivation of hops is a most important industry.

APIARY JOTTINGS.

WE are now passed midsummer, and can pretty well forecast the year's prospects. It is now glorious weather in Somersetshire, and hay-making is going on all round with splendid success. It is only just really begun, the season being after all decidedly backward, so that there will be opportunity for the white clover in many fields to yield its full harvest for our bees. Nor am I without hope that when it reaches its prime there will be a fair lot of honey gathered. At present (St. John's day) not a cell of honey has been visibly sealed up since the middle of May in any of my hives, nor is any to be seen beyond a rare glistening in cells few and far between. Hardly any comb is making either in half-filled hives or in supers, save where swarms have been coated by feeding or have been unusually active. Honeydews have been abundant on many trees, which my bees have resorted to early and late, but I suspect only to keep life agoing. None of it has been stored. I note this dew on oak, lime, beach, filbert, and cherry trees.

My first swarm issued on the 13th out of an improved Abbott-

Woodbury. It was only an average swarm. Pitching on an espalier it was easily hived in the large Woodbury-Phillip's hive, with capacity for lateral extension, now to be tried. I had given them a lot of sectional supers in May, which had some nice comb of last year's make in them. Of course in such a season as this, although crammed with bees for weeks, not a particle of honey was found in them, nor had any addition been made to the comb. Bees began piping immediately, and on the 17th a second swarm issued. This was nearly as large as the former and hived in a Woodbury of my own make, with good comb adjusted to alternate bars. The parent hive was examined at the same time, every bar taken out and inspected, and every royal cell extracted save two or three recently sealed-up, which were left for precaution's sake, although a fine young queen was observed. Ten royal cells were destroyed. All was carefully readjusted, the combs being more conveniently re-arranged. Not a pound of honey was visible in the large hive, but an immense quantity of brood all through the combs was noted with satisfaction, giving promise of future success.

On the 15th a prime swarm, not large, issued from a hive in my tool house, where is a large window looking into the garden facing S.E., where is accommodation for six stocks. This swarm settled on a bush apple tree 4 feet from the ground. A tap brought them down *en masse*, and in five minutes they had possession of an Abbott-Woodbury, and were shifted off immediately to their permanent stand in the open garden.

From this hive, too, issued a second swarm only three days later. Evidently in both cases the bees had been delayed in their plans for swarming by the bad weather so long continued. Piping was observed immediately after the issue of the first swarm. I hived it in a box containing a good lot of empty comb and put it in place of the parent hive. The swarm was in the act of returning, and its queen (offspring of a fine Italian queen imported last October) was caught on the alighting board, and of course given to the cast. So many royal cells were found in the parent hive on examination, some open and many sealed, that it is probable there were other young queens flying about who may have been with this swarm and caused uncertainty in their movements. Ten of the sealed royal cells were cut out and destroyed, also several young queens found about the combs of the parent hive.

The presence of so many royal Italian princesses tempted me to substitute one of them for the only degenerate queen in my apiary. Accordingly the same day we drove the hive of which she was the mother, and having secured and removed her the bees were restored to their hive, over which was set a small super containing three of the royal cells still unsealed; and to make assurance doubly sure I was also able to provide them with a fully grown princess.

All these various operations have succeeded well, and the bees in all hives are working away vigorously. Still I cannot now look for any large quantity of honey with all these divided populations. One strong hive and two weaker ones now recovering from the effects of the tedious spring are all that are left to me unswarmed. It remains to be seen what they will do. Hitherto there has been nothing but disappointment this year.

I may mention as one of the curiosities of the year's experience that in one of the royal cells which we opened were found two young fully fledged but quite dead common bees. They were sealed-up in the usual way. Has anything of this sort been observed before?

Also I may record that in an apiary not far off a hive swarmed and straightway entered an adjoining hive. Full as were the bellies of the swarming bees, they were far from kindly welcomed by their neighbours. A fierce pitched battle resulted, in which many hundreds, perhaps thousands, of the combatants were killed.—B. & W.

OUR LETTER BOX.

BOOKS (*E. Dillistone*).—You must apply to the publishers. (*P. H. G.*).—Consult our "Poultry-Keepers' Manual."

BIRD LOSING ITS FEATHERS (*F. F. Foster*).—At this time of year when the plumage is getting ragged, Spanish hens seem to be beset with the desire to eat every feather that can be got from the body of the cock. It is fair, however, to say it is only those that are in confinement that do this. The treatment you mention is very bad. If the bird in question is at liberty, and has not lost his plumage by the act of the hen, it has come about by fever of the skin. This should be treated with cooling food and with emollients. Rub the naked parts of his body with citron ointment varied with salad or castor oil. Feed on ground oats if you have them, slaked with milk or water, and let the bird have plenty of lettuce. If gone to seed so much the better. We advise you to separate him from the hen. If, however, you think it necessary he should run with her, turn him down at times for a short time. Spanish chickens are naturally very naked in their early youth. We have often had them with only tail and wing feathers, the rest of the body naked, but perfectly healthy. Give the chickens bread and milk, ground oats slaked with milk, and if they are not on grass let them have a large sod with plenty of earth given to them every day. If you cannot get ground oats use barleymeal.

BEES CLUSTERING (*Hankelow*).—You say your bees are clustering outside their hive, even to the extent of filling up the corner of their stand, and you want to know the cause and remedy of this. Some hives that have prepared for swarming by setting queens and have been prevented by weather

from swarming at the time become somewhat morbid and sluggish afterwards. The bees of such hives cluster for weeks, it may be months, before they set queens a second time, and thus prepare for sending off swarms. We have known bees hang outside their hives till the combs inside were filled with honey. Some hives severely affected and afflicted with foul brood are covered with bees in hot weather. The stench of the foul brood drives them outside their hives, and there they commence building fresh combs. Artificial swarming, so easily performed, is the best remedy for the clustering of stocks that will not swarm. Bees should not be permitted to waste their time by clustering outside. After the swarming season is past eking, nading, and supering are resorted to in order to let the bees have playroom enough inside. There is no cure for foul brood. The sooner bees are removed from hives affected with this terrible disease the better both for them and their owners.

TWO SWARMS UNITING (*D.*).—Swarms that issue from separate hives in the same garden at the same time generally unite and alight together in one cluster on a bush or tree, and it is not uncommon for a single swarm to alight on two separate bushes. When this happens there has been a misunderstanding or divided opinion among the bees before they left the hive. Part of the swarm goes to one place, and part to the other. Those without the queen go to the rest. Probably this was the case with yours, though you hived them separately. You may remove the super now from the mother hive.

WINE-MAKING (*J. H. Walford*).—Cooley's "Encyclopædia of Practical Receipts."

REMARKS.

26th.—Fine, hot, sunny morning, rather cloudy in afternoon, distant thunder in W. from 4.51 to 5.30 P.M.; clear fine evening.

27th.—Bright, hot, sunny day, rather more wind than on 26th; very fine night.

28th.—Another bright sunny day, dusty; fine, clear, starlight night.

29th.—The last of the hot days, and not so warm as its predecessors.

30th.—Dull close morning, but 12° cooler than on the 29th; dark storm clouds in S.E. from 10 A.M., thunder first heard at 11.20 A.M., and became heavy about 1.10 P.M. Measurable rain began at 0.43 P.M., and in the first quarter of an hour 0.31 inch fell; rain continued steadily until 7 P.M., when 1.13 inch had fallen. Although far inferior to the storm of the 23rd, even this was a heavy storm.

1st.—Fair all day, but at times very dull and heavy, dark very early in the evening.

2nd.—Dull morning with spots of rain, fair afternoon and evening; very cool.

Four hot days, a thunderstorm, and one very cool day.—G. J. SYMONS.

COVENT GARDEN MARKET.—JULY 3.

OUR Market has been generally active during the past week, and clearances have been readily made. Cherries do not show to best advantage this season, and good samples rule high, while Raspberries bid fair to be a good crop. All household fruits are in good demand.

From observations taken near London during forty-three years, the average day temperature of the week is 74.1°; and its night temperature 60.0°.

HORTICULTURAL EXHIBITIONS AND THEIR INFLUENCES.

HORTICULTURAL exhibitions have done much for the art they are intended to promote, both in this and other countries. Local shows and special shows have given an impetus to cultivation in the districts where such shows have been established, and have brought to greater perfection particular flowers that the special societies have taken under their particular patronage. Exhibitions of greater scope and magnitude have similarly in a broader and more general manner stimulated and encouraged high-class cultivation, as well as having expanded the trade in all that pertains to horticultural pursuits.

It cannot be doubted that the bringing together for purposes of comparison the best produce of our gardens has had a most beneficial effect. Some cultivators by long practice, great perseverance, and close industry have excelled in some particular branch of their profession, and it is only meet that they should reap something more than a mere private approval of their success: they have a just claim to a reward of a more public and tangible nature. Such rewards are provided by horticultural societies and are awarded at the several exhibitions that are held in different parts of the country.

The public recognition thus officially recorded of prominent successes achieved by leading cultivators has had an important influence in raising the standard of horticultural practice throughout the country, has created a spirit of commendable emulation amongst cultivators large and small, and has raised British gardeners to the high and honourable position they now occupy as skilled craftsmen in the art which they so well adorn. In no country in the world is gardening conducted so thoroughly and well as in our own. Some nations may excel in some particular department of floral decorative art; but for solid excellence in the cultivation of flowering plants, for high achievements in the production of fruit, and for general success in vegetable growing, Great Britain is admittedly at the head of all the nations of the globe. Pre-eminent also is this country in the magnitude and richness of its nurseries and the admirable manner in which they are conducted. The seed establishments, too, are with very few exceptions similarly unrivalled; and equally prominent are the various manufactories and foundries wherein are fabricated the structures, heating apparatus, implements, machinery, and manures requisite for the maintenance of horticulture in the commanding position it now occupies.

This position, as before observed, is in a great measure the result of the powerful influence exerted by horticultural societies and their exhibitions—aided, as will be readily admitted, by their natural ally the horticultural press. Thousands of cultivators who have not had opportunities for visiting the great tournaments of skill have yet been made familiar with their nature, and have thereby been imbued with an ambition to be participators of the rewards

offered for skilful work. Thus are gardeners made—namely, by attentive reading, close observation, and unremitting work.

Honours won by the successful exhibitors even at local shows are prized, and rightly so; still more cherished are the rewards won at metropolitan exhibitions; but the most coveted of all honours are those bestowed by the Royal Horticultural Society—the natural and national representative of horticulture in this country. Had not the old Society had the warm sympathy of the leading horticulturists, were not confidence reposed in its management, and were not its administrators trusted as loyal to the objects which the Society was designed to promote, the much-criticised—sometimes abused and sometimes commended—"R. H. S." would not have surmounted so well as it has done the many difficulties it has had to encounter, and would not now have been in a position to expand its influence and extend its usefulness both at its head-quarters and in the provinces.

Catering, as it does, for all classes by giving official encouragement in domestic floriculture to "the million" in the metropolis; distributing its medals over wide districts, and now and again instituting great exhibitions in the populous centres of the provinces, it is doing a large, comprehensive, and important work—work fraught with unalloyed pleasure and benefit to the affluent; and benefit also, of an educational and substantial kind, to the industrial masses of the community, as well as giving an impetus to the great industry of which it is the exponent.

The provincial exhibitions of the Royal Horticultural Society have always been popular and, as great horticultural displays, have been successful. At Bury St. Edmunds, Leicester, Manchester, Oxford, Nottingham, Birmingham, and Bath horticulture has been represented in a truly national manner, and the good influences resulting from such gatherings of the cream of garden products, their producers and patrons, have a deep impress on the national mind which cannot fail being of great public advantage.

Preston is now for the time being the great centre of horticulture. The Show is arranged in all its magnitude, and there is yet time for those who have not yet seen it to make an effort for visiting the great Show of the season, and deriving instruction from the many splendid examples of culture there so attractively displayed. Those, however, who cannot see the Show can do the next best thing—read about it, and we commend the report to their notice.

GRAPES WITHOUT FIRE HEAT.

DOUBTLESS Mr. David Thomson is quite right by suggesting that in a great extent of the "north countries" it is useless attempting the cultivation of Grapes without the aid of fire heat. It is very important also, as pointed out by that experienced cultivator and accomplished writer, that unqualified expressions may possibly result in disappointment. But while it is necessary to remember that Vines cannot be depended on in the north to ripen without fire heat, it is equally well that the fact be recognised that they will ripen admirably over a considerably greater extent of

country in the southern, eastern, and midland counties. How far north they will generally ripen under glass, but without the aid of fire heat, I am unable to state, but I know I have gathered Grapes from open (south) walls as far north as the south of Yorkshire, and have cut fruit from Vines under glass where no fire heat was employed, in the same locality, of really excellent quality and quite fit for a nobleman's table. There are no doubt thousands of gardens in this country where a valuable supply of home-grown Grapes might be produced in plain inexpensive glazed structures without the expenditure of a penny a year in fuel. Yet while that is the fact, it is generally advisable when erecting a vinery for making some provision for keeping the frost out of it in winter, not for the sake of the Vines, which the frost will not then injure, but because the house can be utilised by affording protection for tender plants which are usually requisite for beautifying gardens in summer. The number of small vineries is much greater than formerly in the vicinity of towns, and it is to be hoped they will continue to increase; for ripe Grapes constitute a wholesome and delicious luxury in health, while in sickness they are simply invaluable. Wherever Apricots and Peaches will ripen on the walls in the same district Grapes will ripen under glass without the aid of fire heat.—NORTH LINCOLN.

FUCHSIAS FOR AMATEURS—SOIL FOR POTTING.

No. 1.

FUCHSIAS are amateurs' plants. They are at home on the window sill, in the garden, in the living room, and in the greenhouse. Their fresh foliage is neat, and their flowers are characterised by extreme elegance. "I am forming a collection," writes an amateur, "and should be glad, as I doubt not would many other amateurs, to see some instructions in the Journal for growing the plants well." It would be comparatively easy to impart information on the culture of Fuchsias, but the correspondent alluded to has coupled his request with a statement that renders the matter somewhat difficult. It is to the effect that he has no suitable soil—no turfy loam, leaf soil, or anything of that kind that is so frequently recommended.

As to the matter of soil, it may be as well to state at the outset that the best, most satisfactory, and in the end the most economical plan to adopt is to purchase a bushel or what may be required of some local nurseryman. If a fancier purchases poultry or pigeons, birds, cats, or dogs, he purchases also food for their sustenance. If the pets are worth having the food is worth purchasing. Does not the same rule apply in the case of Fuchsias and other plants? Those who consider the matter well will, I think, reply in the affirmative.

In country districts no real difficulty need occur in the matter of soil, for those who really value softwooded plants and are earnest in their efforts to grow them healthily will always manage to obtain sufficient wayside parings and collect some leaves, a little horse dung and soot, and these mixed together and left in a heap for a year, less or more according to circumstances, will form a compost in which such plants as Fuchsias, Geraniums, &c., will grow in a highly satisfactory manner, other points of culture being correct. But the case is different when would-be cultivators of flowers are dwellers in towns or cities or their immediate suburbs. There are no roadside parings, and possibly no leaves or waste manure of any kind; and in that case they must treat their plants as they would their pet birds, and purchase for them the requisite food. Plants, however, it may be as well to remember, do not require freshly purchased food every day or week, or even month, so that the matter of purchasing soil is not so serious as at first sight it might appear to be.

Amateurs and suburban residents, it may perhaps be opportune to state, are not the only persons who endure great inconvenience, and even incur considerable loss, by the non-purchasing of suitable soil for their plants. Gentlemen—country gentlemen—can have little idea of the importance of affording their gardeners soil suited to the special requirements of particular kinds of plants, or they would be as ready to permit a little soil being purchased as they are to purchase the plants. For the sake of a pound expended in soil many a £5 note has been lost by the premature death of plants, which have perished by the want of a suitable medium in which to sustain them in health. This applies to such plants as Camellias, Azaleas, Heaths, and New Holland plants, or plants generally which require sound peat or pure light turfy loam destitute of lime

to preserve them in a satisfactory and improving condition; yet in heavy clay or limestone districts soil of the nature required for such plants cannot be found. As a matter of fact I have traversed hundreds of acres in a vain search for a load of soil that I knew was essential to the well-being of the plants that had been purchased and for which it was required. The cost of the time so wasted was often greater than would the cost of suitable soil have been if it had been purchased. I mention this with the twofold object of informing suburban amateurs that they have "brethren in distress" amongst professional gardeners in country districts, and also of intimating to country gentlemen who will purchase plants, but who are averse to buying soil, that they ought not to expect their gardeners to make bricks without straw.

Hitherto I have paid much more attention to the second division of my text than the first; but I have good reason for it. The friends at head quarters—for friends they are both to amateurs and gardeners—like experienced cultivators, invited me, when they forwarded to me the amateur's letter, to lay special stress on the question of soil, knowing it was the more important question of the two. And so it is. That is the reason that I have given it prominence.

Yet on the other hand I must say, as a somewhat old cultivator, that soil is not everything in the culture of either Fuchsias or any other plants. Much, of course, depends on the nature of the compost, its texture and components; but of not less importance is the state in which it is used and the manner of using it. I do not hesitate saying that a good gardener and skilled cultivator will achieve greater results with inferior soil than will a bad cultivator with soil of the most perfect character imaginable for the purpose for which it is intended.

In the first place, soil when it is employed must not be so dry as to crumble when grasped tightly, nor yet be so moist as to adhere to the hand after the manner of putty or paste. The mean between these two extremes is not only the best standard to attain, but it is imperative that it be adopted. In the next place the soil must be kept in a sweet yet healthily moist state, and this must be effected by judicious applications of water coupled with efficient drainage. It is very easy to place an inch or two of crocks, such as broken pots or charcoal, into the bottom of a flower pot, and then as easy to throw in soil on the crocks; but that is just what ought not to be done. The drainage must be kept clean and clear by being covered with a layer of turf, moss, manure, or leaves before the soil is placed in the pots. That, too, is imperative. It is not, however, always adopted by amateurs, nor even by some who call themselves gardeners. Another point wherein many amateurs err, and not a few gardeners, is in the habit of watering plants immediately after they have been potted. As soon as a plant has been placed in fresh soil and in a fresh pot it is considered proper to "give it a good soaking." Instead of that practice being proper it is very improper. A plant should never be potted when the old soil in which it is growing is at all dry, nor when the new soil in which it is proposed to place it is similarly devoid of moisture, neither should it ever be watered immediately after the potting has been done.

Those are a few of the principles of culture that must never be lost sight of in the cultivation of Fuchsias, or indeed of any plants, but I have written enough for one paper and will resume the subject on a future occasion.—A NORTHERN GARDENER.

THE SCOTTISH HORTICULTURAL ASSOCIATION.—The monthly meeting of the Scottish Horticultural Association was held on Tuesday, the 2nd inst. at 5, St. Andrew Square. Mr. Dunn, Dalkeith Palace Gardens, President, in the chair. Mr. A. D. Mackenzie read a valuable paper on the "Heating of Horticultural Buildings." He alluded to the various methods which had been tried for heating such buildings, but the only two effective methods were by flues or by the circulation of hot water in pipes. The old flues had been almost entirely superseded, the cost of repairing, their expense, and other disadvantages having contributed to this result. But the system of heating by hot-water pipes had spread to such an extent that it now formed an important item in the industry of the country. He described two methods of heating by water—the one by high pressure with small malleable iron pipes, and the other by low pressure with cast-iron pipes and boilers. Mr. Mackenzie then gave his experience of the various boilers which were used, giving preference to the saddle boiler, and closed with a few hints in reference to the working of the whole system. All the members who took part in the discussion agreed that the saddle boiler was the best in use. Mr. James Grieve read a paper on "Campanulas," in which he enumerated the different kinds and the places from

which they had been first brought to this country, and gave a general idea of the mode of cultivation. The following were exhibited:—Rare specimens of the Iris, *Tropæolum polyphyllum* and *Alströméria chilensis* by Mr. L. Dow; twenty-four new seedling fancy Fancies by Downie & Laird; beautiful flowers of the *Hoya carnosá* by Mr. R. Robertson; and large spikes of Stocks by Mr. W. Black.

SINGULAR BEECH TREE.

THE engraving is from a rough sketch of a Beech tree that grows in the vicarage garden at Sedgley near Dudley. The

Fig. 3.—Singular Beech Tree.

peculiarity consists in this, that the branch denoted as A grows into the branch B, and has become from that point one branch; also the branch C has grown in a like manner into the stem of the tree marked D in such a manner that at first sight it was not clear which of the two places, C or D, the branch had first started from.—HENRY COOPER.

THE BATH AND WEST OF ENGLAND SHOW.

THE floral decorations in connection with the Bath and West of England Show are, I think, deserving of a little comment. The Show is generally described in glowing colours by reporters, and its arrangement is spoken of as if the height of perfection were attained. As the present system of exhibiting has been going on for several years this may not be an inappropriate time for inquiry into its usefulness. This department of course is considered as an adjunct to the agricultural department. When produce of all kinds are brought together in sharp competition the consequence is that the very best is brought from all parts, and a lively interest and some excitement is created among all classes connected with agricultural matters. Why should it not be so in the horticultural department? To most it would seem that is the very thing that is wanted, and if a liberal schedule were issued the Show might be the best flower show of the season. The Committee will do well to see into this matter, and not only endeavour to make

it an exhibition of admiration but also remunerative.—AN OLD EXHIBITOR.

ROYAL BOTANIC SOCIETY.

JULY 10TH.

THIS Society acted wisely in dividing their last summer show into two parts, and offering prizes for cut flowers and fruit a month later than it has been their usual custom to do. The classes for both subjects were well contested, and the quality of the Roses exhibited was far superior to anything we have witnessed this season. Messrs. Paul & Son, Cheshunt, received the highest honours for seventy-two varieties, single trusses; Messrs. Cranston & Mayos, Hereford, were placed second; and Mr. Keynes third. For forty-eight, three trusses of each variety, Messrs. Cranston & Mayos were in splendid form and were awarded the first prize, Messrs. Paul & Son the second, and Mr. Keynes the third. In the class for twenty-four, three trusses of each, Messrs. Paul & Son, Cranston & Mayos, and Mr. Turner were first, second, and third respectively. Mr. Turner was first for twenty-four single blooms, and Messrs. Paul & Son also won five other first prizes for admirable collections. There was only one exhibitor in the amateurs' class—Mr. Davies, The Square, Wilton, Wilts, and he was deservedly awarded the first prize for a collection of twenty-four varieties, three trusses of each.

FRUIT was also well exhibited. Twenty-one classes were provided for in the schedule. The first prize for a collection of nine sorts was awarded to Mr. Miles, gardener to Lord Carington, Wycombe Abbey; and for six varieties to Mr. C. Ross, gardener to C. Eyre, Esq., Welford Park, Newbury. Mr. T. Coomber, gardener to J. A. Rolis, Esq., Hendre, Monmouth, was an excellent second. Pines Apples were numerous shown. The best two Queen Pines came from Mr. Hepper, gardener to C. O. Ledward, Esq., The Elms, Acton; and for a single fruit of the same variety Mr. Dinsmore, gardener to T. F. Blackwall, Esq., received the first prize. Grapes were very good indeed. The best basket of white Grapes was Muscat of Alexandria, sent by Mr. Douglas, gardener to F. Whitbourne, Esq., Loxford Hall, Ilford; and the best basket of black came from Mr. P. Edwards, gardener to Mrs. Tristram, Liphook, Hants. For three bunches of Muscat of Alexandria Mr. Douglas was again to the front, and for three bunches of white, any other variety, Mr. Mowbray won the first place with Buckland Sweetwater. Black Hamburg Grapes came from Mr. Edwards; Mr. Prince, gardener to F. Gretton, Esq., Bladon House, Burton-on-Trent; and Mr. Feist, all exhibiting remarkably good and well-finished bunches. Peaches and Nectarines were finer than we often meet with them so early in the season. Strawberries, Cherries, and Figs were also fairly represented. Mr. Douglas received the two first prizes for Strawberries and Cherries.

An interesting collection of wild flowers was staged by Mr. W. Hills, Prittleworth, and received the first prize. Carnation and Picotees were exhibited by Messrs. Turner, Douglas, and Hooper, who were placed in the order of their names in both classes. Mr. Douglas occupied the first place for twenty-four trusses of stove and greenhouse flowers, and Mr. Morse the second. Mr. Morse was placed first for twenty-four trusses of hardy herbaceous flowers, and Mr. Wheeler second.

Extra prizes were awarded to Messrs. Williams, Henderson and Son, Carfer & Co., Rollisun, Cutbush, and Osborne, who all staged effective groups of fine-foliage and flowering plants in the centre of the great tent, which was greatly admired by the visitors.

Floral certificates were awarded to Mr. Turner for Rose Harrison Weir, Pink Rose Bonheur, Picotees Lady Rosebery, Sultana, and Ne Plus Ultra; to Messrs. Paul & Son, Waltham Cross, for Rose Countess of Rosebery, and a botanical certificate to Messrs. E. G. Henderson & Son for Polypodium Hendersoni. Messrs. Ivery and Son were awarded a silver medal for an exquisite collection of hardy Ferns; and Messrs. Cannell, Hooper, Laing, Turner, and Chard were also awarded extra prizes.

OUR BORDER FLOWERS—FIGWORTS.

WE have no flower in its season that is more attractive than the Foxglove, or, as some call them, Fairies' Gloves. Fairies were often called Folks; hence, no doubt, the origin of the common name Folksglove, and not, as misspelt, Foxglove.

Foxgloves are a rather numerous family, but there are not many met with in general cultivation. There are many places well adapted to their cultivation. They have a fine effect on stony or elevated banks in open spaces in the shrubbery and the herbaceous border, open woods, and by old walls. They are no way particular as to soil, but they delight in a partially rocky medium for their roots, not objecting to an admixture of lime, but they cannot endure stagnant moisture. They require efficient drainage in cultivation. They are increased by seed, which they produce freely; it is best sown about midsummer. Transplant them when large enough to handle. Remove them with balls in the spring where they are intended

to remain. They are also increased by division in the spring when growth has commenced. Some of them, being of tall habit, require staking to prevent them being broken by the wind.

The kinds most commonly met with in cultivation—and then not so often as they ought to be—are *Digitalis grandiflora*, a tall-growing kind of stately appearance, having large flowers approaching bell shape; the flowers are yellow veined with brown; a fine border flower. *D. lutea*, a yellow kind of much dwarfer habit; a very desirable kind. *D. maculata superba*, a beautifully spotted kind, one of the finest of the family; ought to be in all collections of border flowers. *D. ferruginea* is a somewhat delicate subject and requires care. A stock should be kept in hand, as it often disappears after charming us with its beautiful bronzy-coloured flowers. There are many other desirable kinds. Among the spotted kinds there are great beauties that ought to receive more attention than they are at present receiving, which only need to be seen to be appreciated. Our own *Digitalis purpurea* and *alba*, though not herbaceous plants, are worthy of a place in our borders and other places. To see these plants in bloom in their native homes on craggy moors and upland districts, where they perpetuate themselves without our aid, is a sight that is not soon forgotten by the beholder.—*VERITAS*.

EXTRACT FROM THE REPORT OF THE ADELAIDE BOTANIC GARDEN.

THE roserie, with its numerous varieties, the Rose pillars and festoons, covered with thousands of its well-developed flowers, produced an effect which surpassed imagination; but during the middle of October hot winds destroyed this lovely picture in the course of a few hours, as well as the beautiful appearance of the parterres, borders, and ribbon beds, which had presented the same gay appearance as the roserie.

EXPERIMENTAL GROUND.—Arctic Wheat.—Through the kindness of Mr. S. Deering, Assistant Agent-General, London, I received a sample of Wheat taken from a quantity left by the American Arctic expedition ship "*Polaris*" in 1871, which had been abandoned in north latitude 81° 16'.

This Wheat had been left on the beach exposed to the snow and a temperature of 72° to 104° of frost for five years, and was found in a heap by Dr. Ninnis of H.M. ship "*Discovery*" on the return of the last arctic expedition to England.

I received from Mr. Deering one thousand grains, of which I sowed three hundred, and sent the rest to the Royal Agricultural Society for distribution. From the three hundred grains about sixty germinated. The plants grew healthy, and reached to the height of from 3 to 4 feet. It is a bearded Wheat, and ripened in the commencement of January. The ears contained about thirty grains each, which were but small though round and plump. I am sorry the birds destroyed the greater part before it came to maturity. I mention this interesting fact, which proves the assertion that the grain of the cereals possesses a vitality not surpassed by any other seed.

THE SCREW BEAN (*Prosopis pubescens*, *Benth.*).—Sir J. Hooker kindly forwarded about 8 lbs. of the Screw or Mosquito Bean of Aregona, a new and useful vegetable product suitable to warm and dry climates. According to the diary of Lieut. Whipple, in his survey of the line of boundary between San Diego and the point opposite the junction of the Gila with the Colorado River, he states that the welfare of his horses and mules and the success of the expedition were expected to depend on this Bean; that the screw-like pods grow in clusters of eight or ten upon a stem; that both the screw and pod contain much saccharine matter and are very nutritious; that they ripen at different seasons of the year, and are very abundant, each tree producing many bushels; that it has been used for food by men and cattle, and proved of great value to exploring parties.

The tree is said to yield also a gum equal to gum arabic, which is used for medicinal and technical purposes, especially in preparing mucilage, gum drops, jujubes, paste, &c. It has already become an article of export, some 12,000 lbs. having been gathered in Bexar country, and as much more between that and the coast. No doubt the introduction of a tree of such valuable properties would be a boon to South Australia. The seeds received from Sir J. Hooker had, unfortunately, been attacked by a weevil which, it is said, is commenced on the tree, and it is impossible to collect the seed free from weevils; therefore, fearing that very few seeds of this useful tree would germinate, I applied at once to Mr. Watts, Commissioner of the Department of Agriculture, Washington, U.S., for a larger

supply. This gentleman, always most obliging to our establishment, has promised to try his utmost to procure a quantity of seed of the Mosquito Bean for us. About 120 young plants have come up (about 5 per cent.), from the seed received from Kew, are growing satisfactorily, and will be distributed to different districts during the season.

After several attempts I have at last been successful in introducing the very interesting Peruvian tree, *Erythroxylon Coca*, *Lam.* The leaves contain the remarkable power of stimulating the nervous system, in which respect it quite resembles opium. The dried leaves are chewed with a little finely powdered unslaked lime or with the alkaline ashes of the Quinoa. It lessens the desire for food, and it enables the persons who use it to endure greater exertion than they otherwise could, and with less food; but when used in excess it weakens the digestion, producing other disorders, and finally ruining both body and mind.

The tree has been introduced into Brazil, and it is said about 30,000,000 lbs. of the dried leaf are consumed in a year. The young tree is doing well with us.

Worthy of mention and recommendation are the following ornamental plants—viz., *Dracæna Goldiana*, no doubt one of the handsomest *Dracænas*, and unique in character and aspect. It is a native of tropical Africa, and well worthy a place in all collections. *Coleus pictus*, another interesting discovery from Duke of York's Island. The divers bright colours are curiously blended, and the unusual form of the leaves with their marginal teeth give the plant a curious appearance, making it a great acquisition among the leaf plants.

The collection of Ferns was again increased last year with forty species. The collection of Palms was augmented by eighteen handsome species. The following deserve to be mentioned: *Phoenix rupicola*, one of the most graceful among small Palms, and rivaling in beauty *Cocos Weddelliana*. It comes from India, and is a most valuable acquisition, and will occupy one of the foremost positions among Palms. *Geonoma gracilis* is also a most graceful and elegant small-growing Palm. The habit of the plant and beauty of the foliage adapt it admirably to decoration purposes, and it is also one of the most elegant Palms in cultivation.

Among the Aroids introduced the following deserve special mention for their fine variegated and robust leaves—viz., *Dieffenbachia nobilis*, *brasiliensis*, *vittata*, *Parlatorei*; *Curmeria Wallisii*; *Philodendron Lindenianum*, and *Richardia melanoleuca*.

Among the already numerous collection of Marantas known, a new species has arrived—namely, *Massangeana*, which is, no doubt, one of the handsomest of the genus.

PORTRAITS OF NEW PLANTS AND FLOWERS.

MAGNOLIA STELLATA. *Nat. ord.*, Magnoliaceæ. *Linn.*, Polyandria Polygynia.—This has been previously known as a *Buergeria*. "Quite recently it has been named *Magnolia Halleana* by Mr. S. B. Parsons of Flushing, U.S.A., in compliment to Mr. G. R. Hall of Japan, its introducer into America. Like most other introductions of horticultural interest from Japan, this has been in cultivation by the natives of the Islands, having been found in gardens at Nagasaki by Oldham in 1862. It is, however, stated by Franchet and Savatier to be indigenous in woods of Mount Fusi Yama, and in central Nippon, where it forms a small tree. It is a small tree, with the habit of *M. Yulan*, quite glabrous except for a slight silkiness on the young leaves beneath, and the silky hirsute sepals and bracts."—(*Bot. Mag.*, t. 6370.)

FRITILLARIA SEWERZOWI. *Nat. ord.*, Liliaceæ. *Linn.*, Hexandria Monogynia.—Native of Turkestan. "It inhabits the mountains of Turkestan, reaching an elevation of 6000 feet above sea level, and is quite hardy in England. Received at Kew some time ago from Dr. Regel. Mr. Elwes has been very successful with it, his specimens having attained great size and luxuriance."—(*Ibid.*, t. 6371.)

MASDEVALLIA SHUTTLEWORTHII. *Nat. ord.*, Orchidaceæ. *Linn.*, Gynandria Monandria.—"The geographical limits of the genus seem to be limited to the northern and western countries of South America, where they inhabit cool temperate humid regions. *M. Shuttleworthii* was discovered, by the traveller whose name it bears, in the United States of Colombia when collecting for Mr. Bull."—(*Ibid.*, t. 6372.)

DEHERAINIA SMARAGDINA. *Nat. ord.*, Myrsinæ. *Linn.*, Pentandria Monogynia.—A plant with large deep green flowers. "The genus *Deherainia* was established by Decaisne

in 1876, and named by him in compliment to M. Pierre-Paul Deherain, Aide-naturaliste of the museum of the Jardin des Plantes. It was discovered in Mexico near Tabasco, one of the oldest towns of the Mexican Confederation, on the borders of the Chiapas, celebrated as the scene of one of Cortez's earliest and greatest victories. The climate of Tabasco is hot and damp, and, as was to be expected, Deherainia is a thoroughly tropical plant. M. Decaisne describes it as flowering in the stoves of the Jardin des Plantes in May and July. It flowered in the Palm house of Kew in May, when quite small; it was received from Mr. Linden, who imported it into Europe."

—(*Ibid.*, t. 6373.)

TULIPA SAXATILIS. *Nat. ord.*, Liliaceæ. *Linn.*, Hexandria Monogynia.—"This is a very rare Tulip, that has been known for a long time in herbaria as a native of Crete, but has never been introduced into cultivation till now, when it has been rediscovered and brought home by Mr. G. Maw, who, as well as Mr. Elwes, has flowered it successfully this present spring. It is a most distinct and interesting species both from a horticultural and botanical point of view. For decorative purposes we do not get anywhere else in the genus a large flower of a bright mauve-purple colour with a bright yellow eye."

—(*Ibid.*, t. 6374.)

ROYAL HORTICULTURAL SOCIETY'S PROVINCIAL SHOW AT PRESTON.—JULY 10TH TO 14TH.

BURY ST. EDMUNDS in 1867, Leicester in 1868, Manchester in 1869, Oxford in 1870, Nottingham in 1871, Birmingham in 1872, and Bath in 1873—such was the sequence of the past great provincial shows of the Society, and now we arrive at the present, the seventh great horticultural gathering at the busy town of Preston in the populous county of Lancashire.

For the holding of this long-anticipated Exhibition great preparations had been made both by the Executive Committee and exhibitors. The former, under the leadership of the indefatigable Local Hon. Secretary and earnest and accomplished horticulturist, T. M. Shuttleworth, Esq., have brought to bear much foresight and energy in carrying out the requisite work in connection with this really great undertaking. Acting distinct from, yet in unison with, the Council of the Society in London, the preparations, which were unusually extensive, are singularly complete, the final touches having been imparted by the Society's experienced Garden Superintendent, Mr. A. F. Barron.

Arduous as the labours of the Executive Committee have been, they were not lightened by the unfortunate disruption that occurred and so long prevailed in connection with the staple trade of the manufacturing district in which the Show is held. For a long time the utmost anxiety was felt in all parts of the country lest, after all the efforts that had been made and all the responsibility that had been incurred, failure as regards the number of visitors should ensue. But at length, and almost on the eve of the tournament, glad and welcome tidings flashed throughout the land that the night of trade inactivity had ended, and that the morning of prosperity had again dawned. Labour under the conditions alluded to was unusually trying, and there are few—indeed, let us hope none—who could withhold their sympathy from those on whom the duty devolved of working under such depressing and disadvantageous circumstances.

The schedule issued by the Society for this the great Show of the year was also, and fittingly, of considerable magnitude, and was comprehensive, varied, and liberal. The prizes provided by the Society were arranged in six sections—namely, for plants and cut flowers to be competed for by amateurs, and a corresponding section for nurserymen; a trio of "open" classes, including the leading class of the Show, in which £60 was offered in three prizes for sixteen stove and greenhouse plants; sections for fruit, vegetables, implements, tools, and garden appliances, in which two gold and nine silver medals were provided; and a division for cottagers and artisans, the prizes being competed for on the closing day of the Exhibition. The chief prizes offered for plants in the amateurs' section were £20, £15, and £10 for twelve plants in bloom; £12, £10, and £7 for a similar number of plants, half to be in bloom; and £10, £7, and £5 for six plants. In the Orchid classes in the same section £20, £15, and £10 were provided for twelve plants; and £10, £7, and £5 for six plants. First prizes of £12 were provided for nine fine-foliaged plants and for nine exotic Ferns, and premier prizes of £6 were offered for six exotic Ferns, six *Ericas*, six *Crotons*, six new and rare plants, twelve British Ferns, and nine *Fuchsias*.

In the nurserymen's division the principal amounts offered were £25, £20, and £15 for a group of plants arranged for effect in space not exceeding 250 superficial feet, and £20, £15, and £10 for

corresponding collections of hardy plants. For twelve plants not in commerce the prizes were £15, £10, and £7, and for the same number of plants sent out in 1876, 1877, and 1878 the amounts offered were £12, £8, and £6. £15, £10, and £6 were provided for twelve stove and greenhouse plants in bloom, and the same amounts for twelve Orchids. For twenty Conifers and Taxads £15, £10, and £7 were apportioned. For twelve specimen Clematises £12, £10, and £7; and first prizes of £10 were offered for nine fine-foliaged plants and for twelve exotic Ferns.

The chief prizes in the fruit classes were £15, £12, and £5 for collections, and £10 were offered in three prizes for collections of Strawberries in not less than ten varieties. The principal prizes in the four classes for Grapes were amounts of £3. The leading prizes for vegetables were £6, £4, and £3 for collections of eight distinct kinds.

Besides the above prizes and about two hundred others offered by the Society many prizes of great value were provided by the leading nurserymen and seedsmen. Taking them in the order of the schedule we find twelve silver cups and liberal money prizes offered by Mr. William Bull for new plants of his. Messrs. James Carter & Co. provided about £50 for distribution in nineteen prizes for vegetables and Melons. Messrs. Sutton & Sons offered two gold, two silver, and two bronze medals, besides sixteen guineas in money, for collections of vegetables and for Melons and Cucumbers; and last, but not least neither in importance nor value, were the prizes for fruit provided by Messrs. James Veitch & Sons. Twenty-four prizes were offered in this section of the aggregate value of £111. The principal were £15, £10, and £7 for collections of fruit. Extremely liberal prizes were also offered for Black Hamburgh and Muscat of Alexandria Grapes—varieties that were not included in the Society's prize list, also for four varieties of Grapes, Pines, and other fruits.

This recapitulation shows the great encouragement given to insure competition, and now, so far as time and telegraph permits, we submit those awards of the Judges that were made within an hour of our going to press, deferring the completion of our report until another issue of the Journal; but first we may briefly notice the general effect and arrangement of the Exhibition, and also give some tangible idea of its character and magnitude.

The Show, it may be stated, occupies one of the finest sites for the purpose that could be found in the kingdom. Chimneys are generally supposed to "adorn" the landscape in the manufacturing districts, and the "misty haze" that poets dream of and sing of are interpreted in those districts as "smoke." But neither smoke nor chimneys can be associated with the Preston Show. The site is a mile or more from the town: it is an elevated plateau fresh and breezy overlooking the vale of the Ribble, the rising hills beyond which are mapped out by Nature in all her boldness and all her beauty. The grounds of the Preston Nursery Company, which are 150 acres in extent, contain other features of notice besides this fine site for a Royal Horticultural show; and to the Manager of that Company, Mr. Troughton, the Society is much indebted for the substantial aid he has rendered by the construction of roads and otherwise endeavouring to promote the success of the undertaking.

The preparations for this great Show were entrusted to a General Committee of ten gentlemen, with the Mayor of the town (J. Satterthwaite, Esq.) as President. From this body sectional Committees were formed as follows:—Finance and General Administration: Mr. T. M. Shuttleworth, Mr. S. Jennings (London), Mr. Burrows (Treasurer), Mr. Poole, and Mr. Burrow. Ground Committee: Mr. Councillor Nevett, Mr. Councillor Foreshaw, Mr. Troughton, and Mr. A. F. Barron. Refreshments and Decorations: Mr. Alderman Hallmark, Mr. Alderman Ambler, and Mr. Harding. The gentlemen constituting those Committees have worked with commendable zeal in rendering the preparations complete by the specified time in the several departments. On Mr. Cowell, the Assistant Secretary, much labour devolved owing to the unfortunate illness of his chief (Mr. Shuttleworth), for whom great and general sympathy is expressed; but Mr. Cowell has proved himself equal to the emergency, and is discharging his duties with great efficiency.

In the arrangements of the tents and exhibits no attempt has been made to produce a striking impression on the minds of visitors when first entering the grounds. Although the space embraces 30 to 40 acres, yet the Exhibition is somewhat crowded, one portion to a considerable extent hiding another portion; the result is that the Show is much larger than at first sight it appears, and the individuality, so to speak, of the different exhibits is perhaps enhanced by the mode of arrangement adopted.

The tents for the accommodation of the several collections of plants, flowers, and fruit are provided by Messrs. Unite of London, and are very commodious. The chief plant marquee is 260 feet long by 130 wide, the fruit and vegetable tent is 300 feet by 30 feet, and the tent for cut flowers and miscellaneous exhibits is 170 feet by 30. The offices are admirably arranged and substantially built of wood. They afford every accommodation required. They are, indeed, the best erections of the kind we have seen, and reflect much credit on the Executive and on Mr. Nevitt, who designed them and superintended their erection.

The manner in which the ground in the large marquee is laid out demands notice. The design adopted is a modification of the plan recently submitted by Mr. Johnson, landscape gardener, Belfast, to the Council of the Society in London, and is not only a great improvement on that plan, but is really an admirable, tasteful, and successful mode of displaying the plants and collections individually, as well as producing a delightfully varied and picturesque effect when viewed as a whole. Three entrances are provided to the tent—one at each end, and a third in the centre of the south side. A broad curving walk encircles the great enclosure at the proper distance from the sides of the tent to enable the large specimen flowering and ornamental-foliaged plants being arranged on the sloping banks there formed, and which are made to assume a series of small promontories of bold yet smooth outline. Along the centre of the tent, or nearly the centre, the prominent feature is a serpentine sheet of water nearly 200 feet long and 8 to 9 feet wide in the narrow parts between the semi-islands, and more than double that width where the plant mounds are not opposite to each other. There are fifteen of these mounds jutting into the water; they are mostly oval-shaped, 8 or 9 feet by 6 feet. Standing on inverted pots placed in the water are tall Tree Ferns from Mr. Williams's rich stores at Holloway, and the avenue of these stately stems being reflected in the water, which is fortunately clear, constitutes one of the most picturesque features of the Show. On the mounds or semi-islands are the collections of Orchids, new plants, Ferns, highly coloured *Dracænas*, &c., and the general effect produced is rich yet chaste and peculiarly refreshing. The centre of the tent—the water scene—is, of course, considerably depressed, the sides being proportionally elevated, and altogether the tent is extremely diversified and highly imposing. Beautiful views are obtained from the three elevations that have been formed—one in the centre at the southern entrance to the marquee, and the others one near each corner on the opposite or north side of the structure. Besides the curving walk alluded to as encircling the tent, an inner walk also encircles the water, and a large bold pile of rockwork decorated with plants, and from which a miniature cascade trickles, breaks the uniformity of the Show and imparts variety to the marquee.

In addition to the sloping banks round the sides of the building two large irregular-shaped beds 20 to 30 feet in diameter are formed on either side of the tent near the eastern entrance. The one on the left is occupied by the extremely rich and singularly beautiful miscellaneous collection of Messrs. James Veitch and Sons; the opposite mound being jointly occupied by Mr. B. S. Williams, Holloway, and Messrs. Rollisson & Sons, Tooting. The Holloway collection consists of about one hundred choice and rare fine-foliaged and flowering plants of moderate growth. Messrs. Rollisson's render their group distinct and highly attractive by the introduction of several moderate-sized specimens of *Ericas* in the best old and some valuable new varieties. A large box filled with small plants of the beautiful smooth-flowered *E. Dennisoniana* is extremely attractive and commands much attention. In fine contrast are similar boxes of the richly coloured varieties *Massoni* major and *tricolor profusa*. Messrs. Veitch's collection contains the grand *Alloccasias Warroqueana*, *Veitchii*, and *Thibautiana*; a splendid assortment of *Tuberous Begonias*, including the distinct and brilliant *B. Davisii*; choice *Rhododendrons*, *Crotons*, *Orchids*, *Gloxinias*, *Nepenthes*, and other varieties for which the Chelsea establishment is famed. Than these two entrance groups nothing in the Exhibition is more attractive and more generally admired. The corresponding beds at the opposite end are occupied with amateurs' collections.

But speaking of the amateurs we must express strong approval of the magnificent specimens belonging to Mr. Shuttleworth, which constitute by far the finest contribution of its kind in the Show. Both flowering and fine-foliaged plants are grand in size, symmetry, and condition. *Palms*, *Gleichenias*, *Crotons*, *Ixoras*, and *Allamandas* are alike superior, and occupy a prominent position of the tent in a splendid manner. They are not for competition.

Mr. Hammond, gardener to Sir Wilfred Lawson, Bart., Brayton, Carlisle, exhibits some very valuable collections, including excellently grown *Dracænas*, well-coloured *Crotons*, fine-foliage plants in admirable condition, also *Palms*, including the best plant of *Cocos Weddelliana* in the Show, and an equally striking specimen of *Acanthorhiza Warscewiczii*; also new plants, including a splendid example of *Phyllotænum Lindenii*, one of the finest varieties extant. Mr. Hammond also stages a fine example of *Lomaria dalgairensis*, the finest plant we have seen producing fertile fronds.

In the class for nine fine-foliage plants Mr. Osman, gardener to R. B. Dodson, Esq., Beardwood, Blackburn, exhibits a grand *Cycas revoluta* in fruit, also a remarkably beautiful specimen in splendid colour and condition of *Anthurium crystallinum*.

Mrs. Cole & Son and Mr. Tudgey, gardener to T. F. G. Williams, Esq., are the principal exhibitors in the specimen-plant classes, both their flowering and fine-foliaged plants being excellent. It is not necessary, however, to describe them, as they are the same plants that were mentioned in our reports of the York and Leeds Shows. Mr. Pilgrim, Cheltenham, also exhibits attractive flowering plants and excellent examples of ornamental-foliaged plants, as also do the Preston Nursery Company. The same exhibitors

and Mr. Tudgey are the chief exhibitors of *Ericas*; but, with a very few exceptions, the plants are not superior. *Pelargoniums* are only of moderate quality, the season being fully late for these plants.

Ferns are excellent, the principal exhibitors in the classes for exotics being Messrs. Pilgrim, Cole & Son, Tudgey, and the Preston Nursery Company. In the classes for hardy Ferns, E. J. Lowe, Thomas Bolton, and John Atherton, Esqrs., exhibit admirably cultivated plants of choice species and varieties; and Jabez Jones, Esq., stages a novel collection of *Succulents*.

In the groups of plants arranged for effect the only exhibitors are the Preston Nursery Company and Messrs. F. & A. Dickson, Chester. The collections contain a varied assortment of healthily grown plants, but they were not arranged in a particularly striking or artistic manner.

Messrs. Bull, Williams, and Rollisson exhibit collections of new plants, which are closely examined and the merits of the plants are much discussed by those visitors who have not previously had an opportunity of seeing them. They have been frequently seen in London, and their names have been often enumerated in reports of previous shows.

Besides the Tree Ferns, new plants, and miscellaneous collections referred to, Mr. Williams stages a splendid collection of *Orchids* in the class for twelve plants, also *Dracænas* and *Crotons* of remarkable beauty. *Croton Williamsii* and *C. Prince of Wales* are extremely bright and much admired. *Crotons* are excellently exhibited in several of the collections, and play an important part in imparting colour to the Show. The Preston Nursery Company and Mrs. Cole & Son among others stage well-grown and highly coloured specimens. Messrs. Rollisson & Sons arrange splendid *Dracænas*, including the new and striking *D. Smithiana*, rich dark green in colour and very distinct and imposing. They also exhibit six good *Orchids*; *Oncidium macranthum* has splendid flowers, and the plant of *Dendrobium filiforme* is quite charming. Dr. Ainsworth's *Orchids* also command, as they always do, much attention on account of their richness and high culture.

About 140 classes are provided in the schedule, and in all except half a dozen there are entries; in some, notably in several of the fruit and vegetable classes, they are very numerous. The total number of entries for the Show exceeds 800—namely, of plants, 222; of cut flowers, *Roses*, and bouquets, 32; fruit, 223; vegetables, 304; and implements, 30.

GARDEN STRUCTURES.—These are numerous and excellent. Messrs. Messenger & Co., Loughborough, exhibit four span-roofed houses of various sizes and adapted for different purposes—neat, light, strong, well-ventilated, and efficiently heated structures; two span-roofed frames, a range of glass coping, and a tubular saddle boiler with triangular-shaped bars, evidently a powerful boiler; also examples of their patent valves for hot-water pipes, which are admittedly of great excellence.

Messrs. Richardson & Co., Darlington, exhibit a splendid span-roofed house, highly finished, with all the latest improvements in glazing and ventilating. The sashbars are formed so as to protect the putty, and they also effectively provide against internal drip. The ventilation is most ample, not only the apex but the whole length of the rafters and also the front of the house opening by a well-arranged and easily-worked system of leverage. The same firm also exhibit their new hooded horizontal tubular boiler, which is unquestionably a powerful and strongly constructed apparatus. They also exhibit several models of houses, and a capital example of a wall cover for protecting Peaches, &c.

Mr. Halliday, Middleton near Manchester, exhibits eight houses of various sizes; one of them is fitted with slate stages and hot-water pipes complete, another with tanks for forcing, another is wired as for a Peach house, another a vinery, the sashbars being of T-shaped iron, and shows also a capital system of straining wire; another large structure is glazed on Helliwell's patent system, whereby all the woodwork is covered with glass, a capital Strawberry house, and a roomy span-roofed greenhouse. All the houses are light yet strong, and the ventilating machinery is very efficient and works smoothly and easily.

Mr. P. J. Perry, Banbury, exhibits a large, lofty, and highly ornate span-roofed structure, two curvilinear-roofed houses evidently well constructed.

Mr. John Webster, Wavertree, near Liverpool, exhibits a remarkably substantially-built span-roofed house, and different size *Cucumber* frames.

Messrs. Cranston & Luck, Birmingham, exhibit light strong houses, constructed on the principle with which their names are identified, and which have found much favour in various parts of the country.

Boilers are exhibited by various makers. One of the most striking because quite new is Metcalf's "combination" boiler. This boiler combines, with vertical tubes surrounding the furnace, a series of horizontal flues between hollow plates or water chambers, thereby providing a very large extent of heating surface in a comparatively small size of boiler. Mr. Wagstaff, Dukinfield, exhibits tubular and conical boilers which cannot fail being quick in their action and powerful. Mr. Seward, Preston, and Mr.

Harlow, Macclesfield, also exhibit boilers; and last, but not least in importance, Messrs. J. Weeks & Co., Chelsea, London, exhibit examples of their celebrated duplex tubular boilers, which being in operation and doing their work well in various parts of this and other countries renders it superfluous to allude to them in further detail. Their works speak more conclusively than can any words of ours.

Wire and rustic work are also represented: prominent are the rustic bridges of Mr. Henry Inman of Manchester, which span the pool in front of the large tent; near which valuable collections of Conifers are arranged by Mr. Barron of Elvaston and Messrs. F. & A. Dickson of Chester.

Appended is a list of such of the prizes that were awarded by the Judges as we could obtain during the limited time at our disposal.

In the open class for sixteen stove and greenhouse plants, distinct, eight in bloom and eight with fine foliage, the first prize of £30 was taken by J. F. G. Williams, Esq., Henwick Grange, with splendid plants; Mrs. Cole & Son took the second of £20 also with fine plants; and the Preston Nursery Company were awarded the third. In the class for twelve stove and greenhouse plants in bloom (amateurs), J. F. G. Williams, Esq., again took the first prize of £20; and in that for six E. Pilgrim, Esq., was first. For twelve miscellaneous stove and greenhouse plants, distinct, R. Pilgrim, Esq., was again first; Miss Ffarington second, and W. Birley, Esq., third. To R. B. Dodgson, Esq., Blackburn, was awarded the first prize of £20 for twelve splendid exotic Orchids in bloom, and to Dr. Ainsworth the second prize of £15. Mrs. Birchall was first for nine exotic Ferns, distinct, and D. Chapman, Esq., third.

For nine fine-foliage plants, distinct, R. B. Dodgson, Esq., was first; Mr. Hammond second; and J. F. G. Williams, Esq., third. For six of the same Mr. Pilgrim was first; and G. Foreshaw, Esq., second. For six new and rare plants Mr. Hammond was second; and Hon. A. C. C. Maxwell third. For six Crotons, distinct, (amateurs), E. Pilgrim, Esq., was first; and Mr. J. Hammond third; and among nurserymen, the Preston Nursery Co. took the first, Mr. B. S. Williams the second, and Mrs. E. Cole & Son third.

For twelve British Ferns, distinct, Mr. T. Bolton was first; E. J. Lowe, Esq., second; and R. O. Dodgson, Esq., third. For six E. Pilgrim, Esq., was first; J. Stewardson, Esq., second; and Col. Cross third. For twelve exotic Ferns, distinct (nurserymen), Mrs. Cole & Son were first and the Preston Nursery Company second. D. Chapman, Esq., Manchester; took the first prize for two Tree Ferns, and the Preston Nursery Company for three Tree Ferns, distinct, with stems not less than 5 feet high. For six Adiantums, distinct, R. B. Dodgson, Esq., was awarded the first prize, Mrs. Birchall the second, and J. Foreshaw, Esq., the third.

For six Show Pelargoniums the second prize was awarded to W. Birley, Esq.; and for six Zonals (amateurs) W. Birley, Esq., was awarded the first prize; Mr. J. B. Jones the second; and Mr. David Chapman third. In the class for nine Zonals (nurserymen) the Preston Nursery Company took the first, and C. Ryland, Esq., the second, while for nine Fancies (nurserymen) Mr. C. Ryland was first. For six Fuchsias, distinct, in bloom, Mr. Pilgrim was first, Mr. R. B. Dodgson second, and Mr. Tudgey third.

H. Wilson, Esq., took the first for a basket of Roses with Rose foliage only. For twelve Roses, distinct, single blooms, J. Taylor, Esq., was first; Lord Wimmerleigh, second; and T. Bolton, Esq., third. While for twenty-four, General Upton, Milnthorpe, was first; H. Wilson, Esq., Cheadle, second; and W. Warburton, Esq., third. For seventy-two Roses, distinct, single flowers (nurserymen), Messrs. Cranston & Co. were first; and Mr. G. Davidson second. This was a very fine class. For twenty-four, distinct (nurserymen), Mr. Rylands was second; and for forty-eight, Mr. Prince was first, Mr. Corp second. This class contained excellent blooms.

For six Ericas in bloom Mrs. Cole & Sons took the second prize, and the Preston Nursery Company the third. For a group of one hundred miscellaneous stove, greenhouse, and hardy plants, Messrs. W. Barron & Sons were first; Messrs. F. & A. Dickson & Sons second; and the Preston Nursery Company third. For twelve stove and greenhouse plants in bloom the Preston Nursery Company were first, and Mrs. Cole & Sons second; and for a basket of twelve bunches of stove and greenhouse flowers, distinct, Mrs. Cole & Sons were first; the Preston Nursery Company second; and Messrs. Turner Brothers, Liverpool, third.

For twelve new and rare plants not in commerce (nurserymen), the first prize of £15 was won by Mr. W. Bull; and the second of £10 by Mr. B. S. Williams; and for the same sent out in 1876, 1877, and 1878, Mr. Bull was first, Mr. B. S. Williams second, and Messrs. Rollisson third.

For twelve exotic Orchids (nurserymen), Mr. B. S. Williams took the first prize, and for six the first was awarded to Mr. W. Robinson, and the second to Messrs. W. Rollisson & Sons.

For six Tuberous Begonias in flower, distinct (nurserymen), Messrs. J. Laing & Co., Forest Hill, took the first prize with very fine plants, and Mr. J. B. Jones among the amateurs.

For three Palms, distinct, Mr. Hammond took the first; E. Pilgrim, Esq., the second; and Miss Ffarington the third. For

six Caladiums, distinct, E. Birley, Esq., was first. For twelve Dracenas, distinct (nurserymen), Messrs. W. Rollisson & Son took the first prize; Mr. B. S. Williams, Holloway, the second; and the Preston Nursery Company the third; while for six (amateurs) the first prize was awarded to Mr. Hammond; the second to R. B. Dodgson, Esq.; and the third to J. Hardy, Esq.

For twenty Conifers and Taxads, not to exceed 6 feet, Messrs. W. Barron & Son were first; and F. & A. Dickson & Co. second. For twelve Succulents distinct, Mr. J. Atherton was first; and Mr. J. B. Jones second.

For any plants or flowers not specially mentioned in the foregoing classes, Messrs. James Dickson & Son were first; and Mr. H. Boller second.

For the Society's prizes of £15, £10, and £5, for a collection of fruit (open), Earl Somers was first, and Lord Bagot second, in an extremely fine class. For three bunches of Madresfield Court Grapes T. Barnes, Esq., was first, Lord Bagot second, and J. Cowan, Esq., third. For three bunches of any black Grapes except Madresfield Court and Black Hamburg, Mr. Barnes was first, and Lord Bagot second. For three bunches of any white kind except Muscat of Alexandria, Lord Bagot was first, W. Warburton, Esq., second, and Viscount Boyne third. For a basket of not less than 12 lbs. of Grapes, R. Reeves, Esq., St. Helens, was first, Mrs. Vivian second, and J. H. Vivian, Esq., third. For a single fruit of Queen Pine Apple, R. Gretton, Esq., Burton-on-Trent, was first, and Viscount Hill second. For a collection of not less than ten varieties of Strawberries Lord Hill was first, C. Thulluson, Esq., second, and Mr. Mansley third. For two dishes, distinct varieties, Lord Beauchamp was first, Lord Somers second, John Taylor, Esq., taking the third prize. For a single fruit of Melon, which is a fine class, the Hon. C. C. Maxwell was first, the Earl of Crawford second, and W. Blinkhorn, Esq., third.

VEGETABLES.—For a collection of eight distinct kinds, to be shown on separate dishes, Lord Carington was first; R. Walsley, Esq., second; and R. B. W. Baker, Esq., third. For three distinct kinds of Peas, half a peck of each, Sir T. Edwards Moss, Bart., was first; W. R. Winch, Esq., second; and W. Mansley, Esq., third. For three distinct kinds of Potatoes, nine tubers of each, Mr. Iggulden was first; J. Taylor, Esq., second; and Lord Carington third. For twelve Onions, Messrs. E. Smith & Son were first; Mr. Miles, Wycombe Abbey, second; and Mr. Woodhouse, sen., third. For twelve Tomatoes, Mr. Hinds, Otterspool, was first; Mr. Miles, Wycombe Abbey, second; and Mr. Cox third. For one brace of Cucumbers E. Birley, Esq., was first; T. B. Dolby, Esq., second, and Col. Cross third. For a collection of six distinct kinds of salads, to be shown on separate dishes, Messrs. Smith and Son took the prize. For any vegetable not specially mentioned in the schedule, Mr. Cox, Madresfield Court, took the first prize; Mr. Miles, Wycombe Abbey, the second; and Mr. Iggulden, Orsett Hall, the third.

We now come to the special prizes offered by nurserymen, and first we shall notice those offered by Messrs. James Carter & Co., which were restricted to gentlemen's gardeners and amateurs. In the class for the best thirteen dishes of vegetables the first prize of £10 was awarded to Mr. Miles, Wycombe; J. Richardson, Esq., has the second; and Mr. Cox, Madresfield Court, the third. The fourth prize was awarded to Viscount Hill, the fifth to Mr. Hinds, Otterspool; and the sixth to H. Marriott, Esq. This was a very fine class. For the best three dishes of Peas, consisting of Carter's Little Wonder, Culverwell's Telegraph, and Carter's Challenger, J. Richardson, Esq., took the first prize of £5 5s.; Mr. Miles the second of £4 4s.; and Mr. Marriott the third of £3 3s. The fourth prize was awarded to T. Thompson, Esq., and the fifth to R. Thompson, Esq.

Prizes offered by Messrs. Sutton & Sons.—For twelve distinct kinds of vegetables, to include Sutton's Duchess of Edinburgh and Sutton's Giant Emerald Marrow Peas, Canadian Wonder and Sutton's Broad Windsor Beans, the first prize, a gold medal and £5 5s., was awarded to Mr. Cox; the second, a silver medal and £3 3s., to Mr. Iggulden.

The following prizes for fruit were offered by Messrs. James Veitch & Son:—For the best collection in ten distinct kinds, the prizes for which were £15, £10, and £7, Lord Somers won the first prize with a grand collection; and in the next class for the same Lord Bagot was first, the Duke of St. Albans second, and Viscount Hill third. A good class. For the best three bunches of Muscat of Alexandria Grapes Lord Bagot was first; A. Smollett, Esq., second; and B. Shaw, Esq., third. This is a splendid collection. For the best three bunches of Black Hamburg Grapes Lord Somers was first; F. Norris, Esq., second; and R. Prince, Esq., third. A remarkably fine class. For four bunches of Grapes, distinct kinds, one bunch of each, T. Barnes, Esq., was first, and Lord Bagot second. This was a fine class. For three Pine Apples—Coldward, Esq., was first; Mrs. Vivian second; and J. Austin, Esq., second. For six fruit of one kind of Peach, which was a superior class, Earl Crawford was first, Earl Somers second, and W. R. Finch, Esq., third. For six fruit of one kind of Nectarine the Duke of St. Albans was first, Earl of Crawford second, and Lord Bagot third. An excellent class.

Mr. Bull offered silver cups of the value of fifteen, ten, and six guineas to private growers. Mr. Hammond won the first and Mr. Tudgy the second. Mr. Bull also offered cups of the same value to nurserymen, the first of which was won by Mr. B. S. Williams of Holloway. For those private growers who had not previously won any of Mr. Bull's cups the Hon. A. C. C. Maxwell won the second, a silver cup of the value of ten guineas and £7; and the Preston Nursery Company among nurserymen.

The fruit generally is of excellent quality, the collections and Grapes being especially superior; vegetables are also admirably exhibited by the several competitors. Amongst cut flowers the Hereford Roses command much attention by their great excellence. The Show is a success, the town decorated, the company numerous, and the weather dull.

The President of the Society, the Right Hon. Lord Aberdare, arrived at Preston at midnight, and was met by the Mayor and S. Jennings, Esq., the Assistant Secretary. His lordship during his stay in Preston is the guest of W. Burley, Esq., The Larches. The Show was opened by his Lordship at one o'clock on Wednesday, the Mayor and Corporation attending with the mace (the finest in England) and civic paraphernalia, and afterwards a grand luncheon was provided on the grounds, and a gardeners' and exhibitors' dinner was held in the town at night.

The Show is both great and good, and continuing as it does throughout the week, all who are interested in horticulture should make an effort to see it.

The officials, one and all, work earnestly and willingly in seeking to render the Exhibition both enjoyable and successful. Their courtesy is also unfeigned, and they accord an hospitable welcome to all who aid in promoting the work in which they are so laudably engaged. Only fine weather is required to render the Show in every respect what we trust it will be—a Show of "happy memories."

NOTES AND GLEANINGS.

THE thirty-fifth anniversary of that admirable Society the GARDENERS' ROYAL BENEVOLENT INSTITUTION was held at the Albion Tavern, Aldersgate Street, London, on the evening of the 3rd inst. The chair was occupied by Robert Marnock, Esq., who was supported by a large body of gentlemen and horticulturalists; amongst whom we noticed Professor Bentley, J. J. Mechi, Esq., Mr. Sergeant Cox, F. A. Philbrick, Esq., Q.C., Dr. Hogg, Mr. Shirley Hibberd, Mr. T. Moore; Messrs. H. J. Veitch, Williams, Bull, W. Paul, C. Turner, and others interested in the success of the institution. The donations and subscriptions received during the evening were stated by Mr. Cutler, the Institution's excellent Secretary, as amounting to upwards of £600.

THE summer Show of the Botanical and Horticultural Society of DURHAM AND NORTHUMBERLAND, which will open at Newcastle-on-Tyne on the 18th inst., is expected to be both extensive and excellent. The schedule is very comprehensive and the prizes are both numerous and liberal. In the open class for fifty plants in bloom £25 and the Royal Horticultural Society's silver Knightian medal are offered as the first prize, the remaining prizes in the class being £15 and £10. Under the skilled superintendence of the active Hon. Secretaries, Messrs. Taylor and French, good management is assured, and a Show worthy alike of the patronage of exhibitors and visitors is anticipated. Mr. J. J. Gillespie is the acting Secretary.

THE UPPER NORWOOD HORTICULTURAL SOCIETY'S FIRST SHOW was held on the 4th inst. in the grounds of F. Harford, Esq. The exhibits were arranged in a spacious tent 170 feet by 50 feet under the direction of Mr. F. Minchener, the energetic Hon. Secretary, and his colleagues. The gentlemen and gardeners of the district staged admirable collections of plants, and Mr. Wills, Anerley Nursery, contributed a splendid group. Roses were superior, Mr. Coppin, Shirley, being the chief prizewinner. The Exhibition was a highly successful one.

THE summer Exhibition of the BRENTWOOD HORTICULTURAL SOCIETY, held on the 4th inst. in the grounds adjoining Middleton Hall, the residence of the Countess Tasker, was in every respect a complete success. The plants, fruit, and vegetables were equal to, and the Roses—notably those shown by Mr. B. R. Cant, Colchester—much in advance of exhibits on former occasions. Mr. Lane, gardener, Pyrgo Park, Romford, gained the premier prize for plants; and Messrs. Bones, Havering Park, Romford; Bradley, South Weald; Mann, Brentwood; Wise, Hampton House, Warley; Miller, Halstead; and Saltmarsh & Son, Chelmsford, were all winners of one or more first prizes in the various plant classes. Mr. B. R. Cant was first for forty-eight Roses, and Messrs. Salt-

marsh & Son second. In the amateurs' classes Mr. Atkinson, Warley, was first for twenty-four Roses; and Mr. Pemberton, Havering, for twelve Roses. Fruit and vegetables were extensively and well shown both by gardeners and cottagers. Mr. Bones was first for a collection of fruit; Mr. Lane for black Grapes; and Mr. Foster, Warley, for white. Mr. J. Smith, Romford, was very successful in the classes for Strawberries, Mr. Lane was first for eight varieties of vegetables, and Mr. Pope for a brace of Cucumbers. An autumn Show will be held on the 12th of September.

MR. LUCKHURST informs us that EARLY BEATRICE PEACH was ripe at Oldlands, Sussex, on the 1st of July in an unheated Peach house.

WE have received from Messrs. Charles Lee & Son of Hammersmith fruit of the WEEPING BLACK BIGARREAU CHERRY. This is in every sense a true Bigarreau in the fruit, which is of large size and excellent flavour, but it is remarkable from ripening a fortnight earlier than the Bigarreau, and the habit of the tree being weeping, so that it is equally an ornamental and fruit tree. We believe this is the first time it has fruited in this country. It was introduced from the Continent, where it is still a novelty as well as in this country, and where it is known by the names *Bigarreau Pleureur* and *Bigarreau Noir Monstrueux Pleureur*.

THE western entrance to BATTERSEA PARK is now rendered extremely gay by the large and brilliant clumps of *Lilium umbellatum*. This hardy and free-growing and flowering Lily is very valuable for pleasure-ground decoration in the early summer months. Almost rivaling the Lilies in effect are the purple and scarlet Pentstemons which are now flowering in rich masses. The plants have been in the border all the winter, and in the spring the straggling shoots were pruned rather closely. We never before saw such a fine display of Pentstemons so early in the season. The great work of bedding-out in this Park is nearly completed. The carpet-bedding designs are very pleasing, and the subtropical and other beds have been planted with great taste. In a few weeks the Park will be in its summer attire, and will be as enjoyable and instructive as it has been in previous years.

ENGLISH writers have, says the "Journal of Forestry," made the poet POPE'S WILLOW AT TWICKENHAM quite historic. About 150 years ago an English merchant, Mr. Vernon, doing business in Aleppo and Smyrna, brought to Alexander Pope a package of Figs encased in a basket made of unpeeled osiers. Noticing that one of the scions penetrating into the moist Figs was budding Pope carefully cut it out and planted it. Thence grew the famous "Syrian Willow," which became a favourite with the poet, and finally with the English people—so much so that his successor on the Twickenham estate felled the tree to avoid the annoyance of the crowds of visitors which it attracted to his grounds. Its successor is now growing at the Twickenham villa. It was also planted soon after on the banks of the Thames in Kew Gardens, where it still thrives.

WE omitted stating in our report of the LEEDS SHOW that Mr. S. W. Thackray of Burley, near Leeds, exhibited a span-roofed greenhouse glazed on Helliwell's new patent system without putty. The house was extremely light, the whole of the woodwork being covered with glass; the squares appeared also to be quite secure against displacement by high winds, and the roof was evidently watertight.

IN Spain the LEMON-SCENTED VERBENA (*Aloysia citriodora*), says an American contemporary, which we cultivate as a scented garden plant, is collected and stored for winter use. With the Spaniards it is said to form one of the finest stomachics and cordials, and is taken either made into a decoction and drunk cold with water and sugar as a tonic, or with the morning and evening cup of tea. A sprig of about five or six leaves of the Lemon Verbena is first put into the cup, and the hot tea poured upon it. By using this, Spanish authorities assert, "you will never suffer from flatulence, never be made nervous or old-maidish, never have cholera, diarrhoea, or loss of appetite. Besides, the flavour is simply delicious; no one who has once drunk their cup of tea with this addition will ever drink it without a sprig of Lemon Verbena." Perhaps English tastes are different.

OUR correspondent, Mr. Witherspoon, has written as follows on the CROPS in his district (Chester-le-Street) and on his VINES:—"I find that I have more Pear trees than Pears; the finer varieties are very uncertain in the north. With the

good old Hesse, somewhat of an acclimatised sort, I expect that things will be otherwise and there will be a fair crop. Of Apples and bush fruit, including Strawberries, they are variable; but those who in the north depend upon outside fruit for a livelihood will have none the best of it. The ordinary market gardener is the most dependant man in existence. He gets with his few comforts kicks from every corner. He requires all kinds of weather in season, but unseasonable visitations of either sun, rain, frost, or wind, and the myriads of insect pests are all against him. I may be pardoned for saying a few words on my Vines. I truly believe that I have, if not the healthiest, certainly one of the healthiest, vineries in the world. This I admit is rather a sweeping assertion, but I conscientiously believe the assertion is true. Regarding the crop after cutting out until my heart fails to cut more, I find that I have some twelve hundred bunches left, and whilst only as large as peas, I have them 18 inches long, and there are many when ripe that will weigh nearer a stone than a pound."

SEVERAL NEW ROSES have been exhibited this year, some of them for the first time, in a manner that affords evidence of their intrinsic merit. There were a good sprinkling of excellent blooms of Penelope Mayo at the National, and magnificent examples of it at South Kensington on the 3rd inst., where it was certificated. It is questionable if a finer trio of blooms than those referred to have been staged at any exhibition this year. Penelope Mayo is an improving and very fine Rose. Dr. Hogg, exhibited by Messrs. Paul & Son of Cheshunt at the Alexandra Palace and certificated, is a well-formed symmetrical Rose, a trifle smaller perhaps, but possessing a colour of its own, and is very dark and effective in a stand: it is a very promising Rose. Mrs. Baker has been staged in splendid form by Mr. Cranston; and Mons. E. Y. Teas has well sustained its fame as a valuable acquisition by its fullness, richness, and constancy. Of the yearlings those to be made a note of and ordered are Captain Christy's Earl of Beaconsfield (Messrs. G. Paul & Son), Mr. W. Paul's Countess of Rosebery and Duchess of Bedford, and Mr. Turner's Dr. Sewell and Harrison Weir. No new French Roses of the year have as yet even nearly approached in merit those sterling English varieties.

WE never remember observing the LIME TREES OF LONDON in more exuberant health than during the present year. At the present time they are heavily laden with their greenish yellow flowers, which hang in countless thousands from the axil of almost every leaf. Their appearance is chastely beautiful, and their honey-like fragrance imparts to the trees an additional attraction. Not infrequently the trees are infested with insects, but this year they are singularly clean. The Lime is probably at the present moment the most admired tree in the London parks, and many a villa garden is rendered the more enjoyable by the presence of a fragrant and floriferous specimen. The Lime flourishes well in towns, but unfortunately it is one of the first trees to cast its leaves in the autumn.

A CORRESPONDENT, "W. S. B.," speaks highly of the great decorative value of the ZONAL PELARGONIUM APPLE BLOSSOM, which he says is quite as pretty as its name. He describes the plant as being short-jointed and very floriferous, having large but elegant trusses of flowers, white faintly suffused with pink, precisely of the colour and exactly of the form of blossom of some varieties of Apples. "W. S. B." recommends it highly for cultivation in pots for greenhouse decoration during the summer.

"I OBTAINED," writes a southern amateur, "two NEW FUCHSIAS this spring from Mr. Cannell, both of which are not only very distinct from all other varieties in my possession, but are most valuable for decorative purposes by their free-flowering properties. They are Lord Beaconsfield raised by Mr. John Laing, and Beauty of Trowbridge raised by Mr. Lye. Lord Beaconsfield has much of the old *F. fulgens* blood in it, and is vigorous in habit, the flowers being very large, bright, and produced in great numbers. Beauty of Trowbridge is also of robust yet short-jointed growth, and has flowers of great substance; sepals waxy white, corolla rosy carmine. Both these Fuchsias, I believe, possess merit, and are likely to find favour as popular market or decorative varieties."

ONE of the most interesting of what may be termed toy plants, writes "PATER" is the ARTILLERY PLANT (*Pilea muscosa*). It is, says our correspondent, the most admired by his children and their youthful friends of all the plants in

his greenhouse. When laden with its tiny pink flowers and sprinkled with the syringe the pollen becomes liberated and is dispersed in sharp puffs precisely resembling a miniature battery of artillery. This affords much amusement to the children, and affords interest, too, to those who have long passed the period of boy and girlhood days. This fresh-looking free-growing plant ought to be grown wherever there are children to be trained to admire flowers and to take an interest in their nature and cultivation.

STRAWBERRY PIONEER.

THIS new Strawberry, sent out last year by Messrs. Veitch with the prestige of a first-class certificate from the Royal Horticultural Society, proves so good as to be a real acquisition among early varieties. It is as early as La Marguerite, has handsome conical fruit, highly coloured, firm in texture, richly flavoured, and with a slight acidity that is very refreshing. Much of the fruit has been decidedly above medium size with an occasional very large wedge-shaped fruit. The crop was abundant, and the growth of the plants vigorous and robust. So much pleased am I with it that I intend planting a large bed of it, and also giving it a trial in pots next season.

It is all the more welcome, supplying as it does a real want, for we have hitherto had no really good early Strawberry with large fruit that would travel well. Black Prince, Keens' Seedling, and Vicomtesse Hericart de Thury are all undersized, the latter giving only a few respectable berries amongst a multitude of small ones, and the large fruit of La Marguerite is so tender that everyone must be swathed singly in wadding and be handled most carefully, or it will become bruised and spoil.—FRAGARIA.

REIGATE ROSE SHOW.

THE Reigate Rose Association Committee committed the indiscretion of fixing on the same day with the Manchester National Rose Show. This of itself kept several all-England exhibitors away. Taken together with the earliness of the season it contributed to render the Show somewhat scanty, though the greater part of the Roses actually staged were of good quality. In the all-England amateur class Mr. Brown, gardener to A. J. Waterlow, Esq., was first; Mr. J. Sargent was second with a box but little inferior; Capt. Christy being third; and Mr. Ridout, gardener to A. Haywood, Esq., fourth. A Marie Baumann of magnificent form and size in Capt. Christy's box was much admired, as also a box of twelve Teas, shown by Mr. Brown. This has certainly been a great Marie Baumann year. The number of table decorations shown was, as usual, large and of excellent quality. The challenge cup of the Association, for the best box of twelve Roses, was won by the President, George Baker, Esq. The number of exhibitors was considerably reduced by the unfavourable season.

LANTANAS AND THEIR CULTURE.

LANTANAS are not often seen well grown now-a-days, but are nevertheless among the finest of greenhouse decorative plants. Specimens of 3 to 4 feet in height and as much through, perfect half or rather three-quarter globes, studded with nearly globular trusses of bloom, which are borne in profusion from the axils of the leaves, render them very effective and useful either as a decorative or exhibition plant. The Verbena-like heads of bloom are not only pleasing to look at, but in many varieties a grateful fragrance pervades the flower, and is possessed also by the foliage, which is sufficiently abundant to set off the blooms to advantage. The flowers, too, are in different shades of pink, red, orange, yellow, lilac, and white, a few varieties making a grand display in the greenhouse or conservatory from June onwards, forming a capital succession to Pelargoniums, &c.

Not the least of the merits of these plants is their easy culture. Being deciduous they may be stored away like Fuchsias in winter, not taking up room like plants of an evergreen character. Like the Fuchsia they require to be kept dry in winter, but not so dry as to cause the wood to shrivel; they must also be safe from frost. Started at intervals, commencing with a first batch early in March, cutting back the shoots to within two or three joints of the old wood, and placing the plants in a house (as that of a vinery about to be started) with a temperature of 55° to 50°, sprinkling the plants frequently, they soon start into growth. When they have well broken turn them out of the pots, reducing the ball about a third, and return to the same size of pot, working the soil well in amongst the roots. Sprinkle the plants overhead twice

daily, and shade them if necessary from bright sun for a few days, afterwards expose them fully to light and air, keeping them near the glass. When the roots have possession of the fresh soil transfer to pots 3 to 4 inches larger, potting moderately firm, and drain thoroughly. Syringe the plants twice a day, watering moderately until the roots are working freely in the fresh soil, then copiously, alternating the watering with weak liquid manure.

In the case of a good break it may be necessary to thin the shoots by disbudding, removing the weakest and such as are likely to interfere with the symmetry of the plant, and in young plants not well furnished with shoots stopping may be resorted to at the third or fourth joint. Tying and staking must be attended to early so as to secure well-formed speci-

mens, but the habit of the plant is so good that for general purposes, beyond tying down a few shoots as may be necessary to secure symmetrical heads, nothing of the kind is needed. Plants started in March will bloom in late May or early June, another lot started in April will succeed them, and a third lot grown in houses from which bedding plants have been removed will come-in in July and August, when flowers for the conservatory and greenhouse are not over-plentiful.

Propagation is effected by cuttings of the young growths when from 3 to 4 inches in length, taking them off close to whence they proceed, inserting in sandy loam with a little sandy peat, placing in bottom heat, and shading. This is only necessary for plants struck in spring, which afford by far the best specimens, stopping them at the second joint to induce

Fig. 4.—SPECIMEN LANTANA.

side shoots, and those again in like manner being stopped will lay the foundation of the specimen, annually increasing in size and beauty for a number of years. Cuttings of the growing shoots (always avoid flowering shoots for propagation) will strike freely through the summer in sandy soil in a cold frame kept close and shaded. Three parts of fibrous loam, one part sandy peat, and a part old cow dung or leaf soil with a free admixture of sand, form a suitable compost. It is important that the plants do not want for water, or the leaves will turn yellow and fall off.

The plants are subject to the attacks of the white fly or midge, which upon the first few puffs of tobacco smoke falls to the floor and is comparatively out of harm's way; but before fumigating, the floor, stages, &c., should be thoroughly wetted, avoiding, of course, the foliage of the plants; the insects will then either be drowned or killed.

Lantanas when in flower are more enduring with shade from bright sun, and may be placed outdoors in a sunny situation after flowering, with water only to maintain the foliage from flagging, housing the plants again before frost.

There is no doubt of the plants being fine for bedding, plants

in an advanced state for flowering being planted late in May or early in June, and well attended to for water in dry weather. Young plants struck the previous summer are best for bedding purposes, also for decorative purposes in 5, 6, or 7-inch pots.

A dozen select varieties are *Distinction*, *Dom Calmet*, *Eclat*, *Favorita*, *La Manula*, *Lutea grandiflora*, *Marquis de St. La-porta*, *Mons. Rougier Chauvière*, *Ne Plus Ultra*, *Ninus*, *Princess Louise*, and *Victoire*. There are many others of great merit, including the variety represented in the engraving—*Le Grenadier*, colour orange scarlet, fine trusses.—G. ABBEY.

[The engraving is from a photograph of a plant grown by Mr. Parham, gardener to G. May, Esq., Reading. It was exhibited at the Reading Show, and was the most striking of three plants which won the Veitch memorial medal. It was splendidly cultivated and much admired.—EDS.]

LAWNS AT THE PARIS EXHIBITION.

A VERY interesting feature in connection with the horticultural section of the great Paris Exhibition is the international competition between our leading English and the principal

continental seedsmen for prizes to be awarded for the best lawns produced with grass seeds. Some idea may be formed of the extent when it is stated that the whole of the large area known as the Trocadero, as well as a considerable portion of the outdoor space on the Champ de Mars, has been devoted to this competition. England is represented in the Trocadero by only two houses—*i.e.*, Messrs. James Carter & Co., the Queen's seedsmen of High Holborn, London, and Messrs. Webb of Wordesley; whilst for the Continent the gauntlet is thrown down by the following well-known firms:—Jacqueau, Paul Tollard, De la Laye, Torey Vannier, Chouvet, Thibaut, Vilmorin, Andrieux, et Cie., and Dudony.

The most finished amongst these are the lawns of Messrs. Vilmorin and M. Dudony (No. 1, fig. 5), the latter being the introducer of a special manure, and who is understood to endeavour to show by the application of his specific that

valuable assistance can be rendered to the grass during its growth. This, however, remains to be seen, for although the lawns dressed with this manure are in a very fair condition, they are considered inferior to the fine even turf forming a large plateau on the Champ de Mars under the direction of Messrs. Vilmorin.

It is on the English side, however—*i.e.*, the large space on the left hand of the central dome on the Trocadero, that the lawns are in the finest condition, and it is to the credit of England to record that the only lawns in perfect order on the opening day (May 1st) were those of Messrs. Carter; and it is to be regretted that during the heavy rains, which more or less prevailed at the opening ceremony, the crowds of visitors were allowed by the authorities to scramble over those lawns, treading the smooth surface in some places into an uneven bed of mud, and entirely destroying the fine edges. By

Fig. 5.—LAWNS AT THE PARIS EXHIBITION.

great perseverance this damage has since been considerably repaired. The whole of the three large lawns shown in the illustration and numbered respectively 1, 2, and 3, and comprising the larger portion of the space devoted to England, are sown by Messrs. Carter, the smaller plots (numbered 6) being occupied by Messrs. Webb, whose seeds were sown some time later, so that it is as yet early to criticise them. Messrs. Carter were specially invited by M. Hardy, the indefatigable Director of the French horticultural section, to sow all the remaining spaces on the Trocadero with their seed, including the gardens surrounding the cascades and fountains (Nos. 4 and 5). In addition to this they have also sown by desire of the same authority the whole of the lawns on the front of the Trocadero building approached from the charming suburb of Passy. It is well known that our continental neighbours pride themselves on their rapid process of lawn-making, and it is certainly remarkable when it is remembered that Messrs. Carter's lawns, sown April 8th, were cut for the first time with Ransome's mowers on April 29th, or exactly three weeks from the time of sowing.

It must be understood that the preparation of the land has been identical throughout the entire competition, the difference between the English and French process being in the varieties of seed used and the quality and purity of the samples. It is

also necessary to observe that the cultivation, and in fact the entire control of the lawns, was in the competitors' hands until June 1st, when they were handed over to the French authorities.

The preparation of the land is a very elaborate affair, that on the Trocadero especially so. It will be remembered by those who are familiar with Paris that the Trocadero was a huge hill, presenting an uneven and rocky surface, many hundreds of loads of earth having been used to form an even surface, with a top-dressing of what is called "terreau" by the Parisian gardener, and which appears to be the exhausted beds of manure and soil upon which the market gardeners have grown their salads and similar vegetables. It is, however, a useful dressing for the purpose, especially where the natural soil is poor and not readily worked into the smooth surface so desirable when a fine even sward is required.

One word as to hotel charges. There is little doubt but that some of the large hotels in and near the Boulevards are charging exorbitantly, but there are plenty of good hotels where every comfort can be had at reasonable rates. One of the best of these is the Grand Hôtel du Rhone in the Rue J. J. Rousseau. There you can reside at a fixed rate per day, board and lodging and everything (except wines) included, at from 15 to 20 francs per day (12s. to 16s.). Nearly all the servants as

well as the proprietors speak English, and the house is to be well recommended.

THE HEREFORD ROSE SHOW.

[MR. CAMM prefaced his report with a high expression of gratitude for the kindness shown him at Hereford, but we have not space to spare for its insertion.—EDS.]

ROSARIANS are here treated as not only guests to be welcomed and honoured, but as members of the rosarian brotherhood. The West of England Show has been held at Hereford for, I believe, about fifteen years, and although financially it has had often to struggle for existence, it has never failed to be a great success in all other points. Rosarians from all parts of the country flock to the old border city, nestling as it does in the midst of such picturesque scenery, that it is a positive sin to read a newspaper when approaching it in the train. On the last occasion Roses came from Cheshunt, Slough, Torquay, Exeter, Nottingham, Kingston, and many other places of less note. The Colchester Roses were not on this occasion to the front, Mr. Cant's foreman being ill, and the distance and other reasons no doubt keeping that great rosarian away. Messrs. Keynes also did not put in an appearance, but with these exceptions nearly every other great grower sent Roses.

The open class for seventy-two Roses was very well contested. Messrs. Cranston of King's Acre were, of course, here first. Being in fine bloom at the time and on the spot, and having several hundred thousands to cut from, it would be indeed wonderful if anyone could come and beat them at Hereford. I think I have seen this great firm stage a better seventy-two, and my fellow judge (Mr. Baker of Exeter) agrees with me that the year they showed that marvellous box of twenty-four blooms of Horace Vernet, a record of which will be found in the Journal, was the finest ever staged. Be this, however, as it may, there is no doubt that they showed remarkably well on Wednesday. They had a bloom of Louis Van Houtte which I never saw equalled. Mr. Cranston himself said he had never seen such a bloom before. It was of globular shape, of enormous size, and vivid colouring. His bloom of Xavier Olibo was also the finest I ever saw. Comtesse d'Oxford and Serenye were very fine. Sénateur Vaisse was splendid. He showed also a bloom of that tiny variety Comtesse de Chabillant. But here we had a large bloom of a rather lighter shade than ordinary seen of perfect form. His blooms of Charles Lefebvre, Horace Vernet, and other dark Roses, though of lovely form, were all of lighter shades of colour than usually seen, and Mr. Cranston informs me that all these Roses have come light this year, owing no doubt to the excessive rainfall. Marie Baumann was splendid both here and in a superb box of twenty-four blooms which gained the first prize, and which were quite equal to Messrs. Curtis's stand of the same variety at the Crystal Palace. Annie Wood, Marie Cointet, Elie Morel, Le Havre, François Michelin, and Etienne Levet were all grand. Messrs. Davidson of Whitecross Nurseries, Hereford, showed very finely and were placed second in this class. I have been much struck every time I have visited Hereford by the great improvement this firm is making in showing Roses. Each year they are better than the last, and on this occasion, if their great neighbour had been absent, they would have attracted great attention to their stands. Their best blooms were Marie Baumann, Madame Lacharme, Xavier Olibo, Eugénie Verdier, Madame Georges Schwartz, Etienne Levet (grand), Général Jacqueminot, and Abel Carrière. Mr. W. Lee of Kingston was third.

For forty-eight trebles Messrs. Cranston were first with marvellous good clusters, Mr. Davidson second, and Mr. Grove of Hereford third. For twenty-four singles Messrs. Cranston were again first; Mr. Griffiths of Tillington, an old foreman at King's Acre, second; and Mr. Frettingham of Beeston third.

For the close class of seventy-two (that is, excluding Hereford) Mr. George Paul was first, Mr. Turner of Slough second, and Mr. Frettingham third. Mr. G. Paul's blooms were very fine indeed considering the distance they had come, and so were Mr. Turner's. The trebles and other classes were well filled with the exception of one class, that of eighteen trebles for nurserymen.

We now come to the great amateur contest for the challenge cup given by Messrs. Cranston & Co. for the best thirty-six Roses, to be won twice. This cup was won in 1876 by Mr. Thos. Jowitt of The Old Weir, Hereford, and in 1877 Mr. Baker of Heavitree came in his might to Hereford and carried it off. It was now pretty certain that one or other of these giants would finally win the cup. The interest was very great. Mr. Jowitt perhaps a little weakened his chance by showing at Torquay the day before, where he carried off seven first prizes. Mr. Baker wisely reserved all his strength for the great contest, where he should meet his noted rival on his own ground. In order to be as fresh as possible Mr. Baker followed the plan he has adopted of late years when showing at Hereford. He cut his blooms late the evening before the Show, took them as far as Gloucester by the mail train, and the next morning went on to Hereford, getting there just in time to stage. Mr. Jowitt had about nine hours' more time in his

favour and only a journey of three miles, so that the odds were apparently in favour of the Hereford champion. Close was the contest, severe the fight, and grand the triumph for the west when Mr. Baker in the long run carried the cup off for the last time to Exeter.

The two stands were different in several points. Mr. Jowitt's was more even, while Mr. Baker's had many much finer and larger blooms. Mr. Jowitt's had also more Teas, and his stands were more varied as to colour and the arrangement was a little better, but nothing could come up to the size and grandeur of Mr. Baker's back row with the exception of two Roses. It was freely owned by most rosarians present that Mr. Baker spoilt his box by inserting in his back row a large but coarse bloom of that objectionable variety for exhibition, Madame Charles Wood. His Capitaine Christy also was by the time the public were admitted a little past, and three Roses in the front row were a little undersized. When this has been said nothing remains that can be urged against his stand. His other blooms were perfection. He had a bloom of a Rose little known called Comte de Rainbold, a dark, full, somewhat cupped Rose, which created quite a sensation. Mr. Robert Veitch is one of the very few nurserymen, if not the only one, who possess this Rose, and the rush upon his plants will be very great next autumn. Once more Mr. Baker astonished the company with his blooms of Marie Baumann, Charles Lefebvre, and Marie Rady, and many others too numerous to name here, while his freshness and purity of colour were marvellous considering the distance he had come. Mr. Jowitt's thirty-six were also a great treat. He staged them in one box, and it was a perfect treat to see them. As I have said, a more even lot has seldom been seen. His best bloom was Thomas Mills, while his Comtesse d'Oxford, Louis Van Houtte, Triomphe de Rennes, and other Teas were also very good.

Mr. Bulmer the energetic Secretary was third with, among others, I think the best bloom in the Show, and the only specimen I have seen of it this year. In his back row there was a bloom of Comtesse de Nadaillac which I shall never forget. This lovely Tea Rose is a very bad grower, and I have never yet seen it shown half the size of Mr. Bulmer's. If there had been a fourth prize, or if a consolation prize is eventually given by the Society when they read this report, no doubt I shall win it. Meantime truth compels me to say that your correspondent was left out in the cold.

The other amateur winners in other classes were for twenty-four, Mr. Baker first; Mr. Jowitt and Mr. John Arkwright of Hampton Court equal second. I won't say who was third, but will leave it to the imagination of your readers. For eighteen trebles and for twelve singles Mr. Baker was again first.

The Herefordshire amateurs in their close class showed uncommonly well, particularly Miss Bulmer, and the whole Show was a good one. Mr. George Paul was first for Teas, but I am vain enough to think I ran him very close. For twenty-four Roses of a sort Mr. Cranston staged a marvellously good stand of Marie Baumann which was first, and the other prizes went to the same Rose. Jean Liabaud won the first prize for twelve blooms of one new Rose and again brought Mr. Cranston's name to the front. There was no competition for the Veitch Memorial prize, and Mr. Cranston won Mr. Arkwright's prize for twelve Teas and twelve H.P.'s shown in the same stand. The bouquets and table decorations were very good, and everything connected with the arrangements was not to be surpassed.

The only drawback—the one crumpled Rose leaf which disturbed my comfort, was the band. Fancy, Messrs. Editors, instead of the string Rhine band which used to delight all lovers of music at this Show, twelve or thirteen brazen instruments without a reed or a string to mitigate their ferocity, went blaring and pounding away till they drove every lover of music to distraction, and effectually got rid of me. A militia band at the head of a regiment or in the open air is all very well, but in the Shire Hall, Hereford, it is something too terrible. Mr. John Cranston entertained the principal exhibitors in the most hospitable manner, and few of us will forget the stroll round his nursery in the cool of the evening, or the splendid entertainment he gave us; but above all other things his genial welcome, his unmistakable love for Roses and rosarians, the pleasure with which he greeted us as friends and guests, this will not be forgotten by us as long as the Rose continues to be the queen of flowers. It is with almost a sad heart that I thus bid farewell to the Hereford Rose Show for the year 1878; and were it not for the thought that, all being well, in another twelve months I shall be there again, I should hardly have the courage to sign my name to this letter.—WYLD SAVAGE.

SPIRÆA ARUNCUS.

I HAVE known this plant for fifty-one years, and last year I saw it great perfection at the gardens of A. Fletcher, Esq., Salton Hall, East Salton. I induced the gardener Mr. Barrie to measure it. The plant was 5½ feet high and 18 feet in circumference. There were ninety flower stems on it 18 inches

to 2 feet long. There were four or five plants growing amongst some dwarf shrubs, and it was a treat to see them. It occurs to me this variety would be very suitable for forcing, but for growing in the margin of a shrubbery I know nothing to surpass it. In my opinion it surpasses the shrubby sort *S. acerifolia*.—J. ADDISON, *East Mains, Broxburn, Edinburgh*.

THE ROSE ELECTION.

THE "exhibition" Rose election of 1877 was not altogether a failure, indeed it appears to me to have originated a correspondence on the merits of an exhibition Rose which has permeated the pages of our Journal with the aroma of Roses throughout the damp wintry times and the cheerless spring, until "it is time of Roses" again.

With the consent of our Editors, and strengthened with the experience of the last election, I propose this year to make it again an exhibition election, and I repeat the question for solution.

It will save electors, and it will save myself much time (of which article I have less in stock), and trouble (the stock here being also low), if they would answer the question carefully and as soon as they conveniently can.

Every elector must have taken a prize at the larger exhibitions, or several prizes in local competitions, and if adding the second forty-eight for Mr. Curtis's suggestion, they must have taken a prize for at least forty-eight varieties in a stand.

Name the best forty-eight exhibition Roses according to your experience in your soil. Mark the best twelve of these with a cross, the next best twelve with two crosses, or distinguish these twelve in any simple but clear manner.

Mr. Curtis suggested to me last year trying to arrive at the best ninety-six varieties. Any exhibitor qualified to vote on this will oblige by adding a second forty-eight to the list.

This will entail considerable additional labour. I will try to get out the first forty-eight as early in September as possible, and cannot receive lists for either after the 15th of August.

In the case of nearly similar Roses up to forty-eight varieties, as, for instance, *Lælia* and *Louise Peyronny* equal; *Ferdinand de Lesseps*, *Exposition de Brie*, and *Maurice Bernardin* equal; *Marie Finger* and *Eugénie Verdier* equal; *Mons. Boncenne* and *Baron de Bonstetten* equal; please name only one in the forty-eight varieties, whichever is considered best. The poll will show the position of each, but they will be classed as one Rose.—JOSEPH HINTON, *Warminster*.

NATIONAL ROSE SOCIETY'S PROVINCIAL SHOW.

MANCHESTER, JULY 6TH.

THE National Society may be congratulated most heartily on the success of its first provincial Exhibition, for Manchester has never seen such Roses, and to many it must indeed have been a revelation of the queen of flowers. The local papers are full of praises (and what is more, the Botanical Society is full of money by its venture), pronouncing it "as a whole one of the most successful, as well as one of the most enjoyable ever held at Old Trafford, and that is saying a good deal." I know not how many visitors there were, but the gardens were crowded, and as to the house where the Exhibition was held, it was hopeless to attempt to get near the Roses after the throng commenced to arrive. All this is very encouraging, but it must be recollected that it adds but little to the Society's revenues to hold an Exhibition at which northern growers might compete formed part of its programme, and loyally and faithfully carried it out; but if it is to be repeated there must be a large access of members north of the Trent, for surely if the Society is willing to give of its funds to meet the claims of northern rosarians, they are bound to use their efforts for the welfare of the Society.

It will be seen from the list of awards appended hereto that most of our great growers for sale were present in force. Messrs. Cranston, Cant, Paul, and Prince were there, while Davison of Hereford, Merryweather of Southwell, Frettingham of Nottingham, and Francis & Arthur Dickson of Chester, also entered the lists; while amongst amateurs the well-known names of Jowitt, Hole, and Pochin figure. Mr. Soames, who is coming with strides to the front; Messrs. Davenport, Hand, Brown, and others show that the north has won its share of honours, although we may hope another year that there will be a larger accession of exhibitors. I am writing in the house of a friend whose Roses would, I am convinced, have won honours had not his modesty kept him back. It is worthy of note that an amateur ventured in a stormy night to cross the Channel from Ireland; and although his Roses suffered by the voyage, yet he was enabled to set up a very creditable stand and take a third prize in forty-eights.

In looking through the various stands one found that there are

certain varieties which figure in them all, and that therefore to give a full list of prizewinners would be merely to repeat those given of the Society's Exhibition at the Crystal Palace, and I shall therefore content myself with singling-out a few of the more conspicuous blooms. I think the palm of merit for the premier Rose of the whole Exhibition must be given to the bloom of Reynolds Hole in Mr. Cranston's stand. It was shown well by Mr. Cant and Mr. Wm. Paul. But this bloom was a marvellous one; for form, substance, and colour it left nothing to be desired. Indeed, in looking at the Rose shows of the year so far, it seems to me to be the most remarkable of the season, François Michelon which so astonished us last season being nowhere this year. Another grand bloom was his Duchesse de Morny, magnificent in its outline, and grand in substance and size; then Comtesse de Serenye, Xavier Olibo, The Rev. J. B. M. Camm were also very fine. In Mr. Cant's stand, Reynolds Hole (already noticed), Souvenir d'Elise, Horace Vernet, La Boule d'Or, Niphotos, were very fine; and Messrs. Paul & Son's, which ran Mr. Cant's very close, contained grand specimens of Mrs. Laxton, Reynolds Hole, Marie Baumann, Duke of Edinburgh, Alba Rosea, and other well-known kinds.

Amateurs' stands contained some very excellent flowers. Canon Hole's—Niphotos, Sophia Tropot, Capitaine Christy, and Comtesse de Nadaillac; the Rev. E. N. Pochin's—Lord Macaulay, Duke of Wellington, Alfred Colomb, and Marie Baumann; Mr. Jowitt's—Devoniensis, Général Jacqueminot, and Marie Baumann; Mr. Coddington's—Miss Ingram, Niphotos, Madame Schmidt, Marie Rady, Homère, and Triomphe de Rennes being amongst the most remarkable flowers shown. Mr. Soames's stand of twelve contained some really grand blooms.

Teas and Noisettes were well shown both by nurserymen and amateurs. Amongst the most telling flowers were Devoniensis, Caroline Kuster, Souvenir de Mons. Pernet, La Boule d'Or, Souvenir d'Elise Vardon, Catherine Mermet, Jean Ducher, Comtesse de Nadaillac, Belle Lyonnaise, and Alba Rosea. In Mr. Paul's stand of new Roses Jean Souper, Sultan of Zanzibar, Marguerite Brassac, Mrs. Laxton, and Mons. Fournier were the most remarkable, and were really fine. The three winning stands of Marie Baumann contained some splendid blooms, although the colour in some had flown. Not so Charles Lefebvre, both stands being defective and in many instances showing the eye. The stands of La France were good, but I have seen better. Messrs. W. Paul and Son of Waltham Cross exhibited ten boxes of Roses containing some fine blooms, and also a box of seedlings, to one of which, Countess of Rosebery, a first-class certificate was awarded, the same honour being given to Messrs. Paul & Son of Cheshunt for Mrs. Laxton.

Thus must end my record of the National Society's Show. I should have liked it to be fuller, but after having had to superintend the whole arrangements of the Show on a very hot morning, and then to act as judge, it was very difficult for tired human nature, especially at threescore, to squeeze through a crowd to take notes, and had it not been for a mandate from head quarters which I received at midday I should not have made this; and so I hope the readers of our Journal, gentle or otherwise, will take the will for the deed.

NURSERYMEN.—Seventy-two distinct, single trusses.—First, Messrs. Cranston & Co., Hereford; second, Mr. B. R. Cant, Colchester; third, Messrs. Paul & Son, Cheshunt; fourth, Mr. J. Davison, Hereford; extra, Mr. Henry Frettingham, Nottingham. Forty-eight distinct, three trusses of each.—First, Messrs. Cranston and Co.; equal second, Messrs. Paul & Son, and Mr. B. R. Cant. Twenty-four distinct, three trusses of each.—First Messrs. Cranston and Co.; second, Mr. B. R. Cant; third, Mr. J. Davison. Twenty-four distinct, single trusses.—First, Mr. J. Prince, Oxford; second, Mr. W. Corp, Oxford; third, Mr. H. Merryweather, Southwell. Twelve Teas or Noisettes, distinct, single trusses.—First, Messrs. Paul & Son; second, Mr. B. R. Cant; third, Mr. J. Davison.

AMATEURS.—Forty-eight distinct, single trusses.—First, Rev. Canon Hole, Newark; second, Mr. T. Jowitt, Hereford; third, Mr. D. H. Coddington, Drogheda, Ireland. Thirty-six distinct, single trusses.—First, Rev. E. N. Pochin, Leicester; second, Rev. Canon Hole. Twenty-four distinct, single trusses.—First, Mr. T. Jowitt; second, Rev. E. N. Pochin; third, Rev. Canon Hole; fourth, Mr. J. Mayo, Oxford. Twelve distinct, single trusses.—First, Mr. A. J. Soames, Bourne; second, Mr. J. Lakin, Chipping Norton; third, Mr. J. Davenport, Altrincham; fourth, Mr. W. Hand, Newcastle-under-Lyme. Six distinct, single trusses.—First, Mr. A. J. Soames; second, Mr. J. Lakin; third, Mr. J. Brown, Heaton Mersey. Six distinct, single trusses of district-grown Roses.—First, Mr. J. Brown; second, Mr. W. H. Palfrey, Altrincham; third, Mr. J. Davenport. Twelve Teas or Noisettes, distinct, single trusses.—First, Rev. Canon Hole; second, Mr. T. Jowitt; third, Rev. E. N. Pochin.

OPEN CLASSES.—Twelve new Roses, distinct, single trusses, must not have been in commerce before 1875.—First, Messrs. Paul and Son; second, Mr. J. Davison; third, Mr. H. Frettingham. Twelve single trusses of Marie Baumann.—First, Messrs. Cranston and Co., Hereford; second, Messrs. Paul & Son; third, Mr. B. R. Cant. Twelve single trusses of Charles Lefebvre.—First, Messrs.

Paul & Son; second, Messrs. Cranston & Co. Twelve single trusses of La France.—First, Messrs. Paul & Son; second, Mr. G. Davison; third, Mr. H. Frettingham. Prizes were offered for twelve single trusses of Marechal Niel, but there were no entries. Messrs. W. Paul & Son were highly commended for a collection of ten boxes of Roses.

First-class certificates were awarded to Messrs. W. Paul & Son for Rose Countess of Rosebery, and Messrs. Paul & Son, Cheshunt, for Rose Mrs. Laxton.—D., Deal.

ORIGIN OF THE RIBSTON PIPPIN APPLE.

WE have received the following from an esteemed correspondent:—

"On the 1st September, 1693, in the fifth year of King William and Queen Mary, Robert Clemesha of Goldsborough, brought his son Robert to be bound to the Honourable Robert Byerley of Mettridge Grange, in the county of Durham, as a gardener. His master covenants to find him sufficient meat, drink, clothes, lodging, and washing suitable for an apprentice. When bound he signs with a cross (x), not being able to write. The Honourable Robert Byerley had land near Goldsborough I know from receipts of rent in my possession. Perhaps Clemesha lived at Ribston Park, in after life was chief gardener there, and had given him the pip of an Apple brought from France which he was desired to cultivate. This he succeeded in doing, and the fruit was much approved, and takes the name of the Ribston Pippin from the locality where it was first raised. This tree died in 1849. The indenture in my possession was ready to drop to pieces, so I had it glued to cartridge paper and have presented it to the Hull Philosophical Society, in whose museum it is now deposited."

We are very glad to be able to publish this information, and we print also the following for comparison from the last edition of Dr. Hogg's "Fruit Manual."

"There is no Apple in this country which is more generally cultivated than the Ribston Pippin. It did not become generally known till the end of the last century, and it is not mentioned in any of the editions of Miller's Dictionary or by any other author of that period, neither was it grown in the Brompton Park Nursery in 1770. . . . The original tree was first discovered growing in the garden at Ribston Hall near Knaresborough, but how, when, or by what means it came there has not been satisfactorily ascertained. One account states that about the year 1688 some Apple pips were brought from Bouen and sown at Ribston Hall near Knaresborough; the trees then produced from them were planted in the park, and one turned out to be the variety in question. The original tree stood till 1810, when it was blown down by a violent gale of wind. It was afterwards supported by stakes in a horizontal position, and continued to produce fruit till it lingered and died in 1835. Since then a young shoot has been produced about 4 inches below the surface of the ground, which, with proper care, may become a tree, and thereby preserve the original of this favourite old dessert Apple. The gardener at Ribston Hall, by whom this Apple was raised, was the father of Lowe, who during the last century was the fruit-tree nurseryman at Hampton Wick."

THE HORSHAM ROSE SHOW.

AMONGST the many votaries of the queen of flowers Horsham holds a forward place, and her two-years-old Association bids fair to be very soon a very leading one in south-east England, not least through the liberal step taken by the Committee of throwing open to all England a twenty-four, twelve, and twelve-of-the same-kind class. On July 2nd the second annual Show was held in the Assembly Rooms, a place admirably adapted for the number of Roses requiring to be staged, and the result was a show of very considerable merit. Not only in the all-England class, but also amongst the members' boxes, fine Roses were exhibited. A magnificent triplet box of Mr. W. G. Sharp of Birchen Bridge was particularly noticeable. Finer blooms of Marie Rady and Annie Wood it is scarcely possible to imagine, immense size being attained without loss of colour or coarseness. In the all-England classes the first prize for twenty-four was taken by Mr. Prince of Oxford, the second by Mr. Ridout, gardener to J. B. Heywood, Esq., of Reigate; Mr. Piper of the Uckfield Nurseries being third, and J. H. Pemberton, Esq., fourth. In the twelve of any kind Messrs. Prince and Piper were an easy first and second with very large and fine blooms, the Rev. Alan Cheadle being third, and J. Graveley, Esq., Cowfold, fourth. Mr. Prince was also first with a magnificent dozen of Capitaine Christy, the Rev. R. Cox-Hales being second with a very even box of Marie Rady. A fine box of Paul

Verdier was also shown. This old Rose, though not a perpetual, is worthy of more attention than it receives.

The arrangements of the Hon. Secretary, W. H. Saddler, Esq., were very complete and effective, but the unfavourable weather prevented the attendance which might have been anticipated, and it is to be feared operated unfavourably on the funds of the Society. This Society adopts the somewhat novel plan of letting all-England amateurs and nurserymen exhibit together. The former, of course, are somewhat overweighted; the result is, however, a large average of high-class flowers.—A. C.

TORENIAS ASIATICA AND FOURNIERI.

TORENIA ASIATICA is one of the most distinct and elegant of plants for the decoration of stoves in spring and greenhouses in summer. As a basket plant it has few superiors, its elegant pendent growth and richly coloured flowers rendering it singularly attractive. As a prize plant for boxes and elevated stages, also for placing on isolated brackets, it is very suitable. It is further well adapted for cultivation in pots, its growth being loosely trained round sticks or wire trellises. It, however, shows to the greatest advantage when grown in baskets. Its cultivation is extremely easy, but its preservation through the winter is often somewhat difficult. Cuttings should be struck in late summer, and when rooted be potted in a rough compost such as nodules of peat, a little very turfy loam, and lumps of charcoal in equal proportions, the plants being wintered in small pots on the shelf of a light and well-heated stove. When fairly growing in the spring richer soil may be afforded them, and liberal supplies of water; they will then grow luxuriantly and flower with great freedom. Cuttings struck now will make attractive plants for flowering in late autumn and early winter. This is a good old plant somewhat too much neglected.

T. FOURNIERI.—This is a most valuable acquisition for which British gardeners are indebted to the celebrated French firm of Vilmorin, who sent plants or seeds to Chiswick. These were well grown and flowered by Mr. Barron, and a first-class certificate was voted to the plant last year by the Floral Committee of the Royal Horticultural Society. This year plants have been again exhibited at South Kensington by Mr. Barron in a manner which stamps this distinct Torenia as a plant of high excellence for summer decorative purposes.

The plant is quite dissimilar in habit from T. asiatica, which is a trailer, the new introduction being suffrutescent, and is very dwarf and stubby, especially when grown cool—that is, not drawn in a high stove temperature. It flowers with great freedom and is richer in colour than its well-known prototype, inasmuch as each rich purplish violet flower has the addition of a rich orange blotch. The plants exhibited last week did not greatly exceed 6 inches in height, and they were a complete mass of rich flowers set in bright green foliage. The sprays had no stakes or other supports, the short-jointed growth being sufficiently strong to retain their upright position and sustain the flowers without any extraneous aid.

The plants referred to were grown from seed saved at Chiswick last year. It was sown in the spring, and the plants have been grown, after they were fairly established, in an unheated house. They will no doubt flourish admirably in a cold frame during the summer months. For front rows in greenhouses and conservatories this Torenia is eminently suited. In the colour of its flowers it is distinct from all other plants; indeed it combines richness with elegance in a remarkable manner.

All nurserymen should obtain a supply of seed of this beautiful summer-flowering greenhouse annual, and all gardeners should order a packet next spring. If they grow the plants as well as those which have been grown at Chiswick, and this they may do with ordinary care, they will have good reason to be satisfied with what is one of the most charming of the "floral simplicities" of recent introduction. Torenia Fournieri is sure to become popular, and the sooner the better.—J. WRIGHT.

WILKINSON'S REGISTERED PEA TRAINERS.

WHEN travelling through the southern parts of Lancashire about eleven months ago I had the good fortune to visit a well-kept garden belonging to Captain J. H. Birley, called Brookside, in the village of Newton-le-Willows, three minutes' walk from the Newton Bridge station of the London and North-Western Railway. While accompanying the gardener round this snug little spot I saw a novelty which especi-

ally took my attention. It was a row of Peas, which instead of a row of pea sticks appeared to be supported by two rows of espaliers, but which afterwards proved to be Wilkinson's registered pea trainers. The row seemed so neat and tidy that I was induced to take a good look at what I thought must prove a benefit to gardeners who have a difficulty in procuring pea sticks. So simple is this arrangement that a child might understand it. The strainers for the wire are so small that they can hardly be detected a few yards off, and with anything like ordinary care they will last twenty years.—S. W. S.

NOTES ON VILLA AND SUBURBAN GARDENING.

KITCHEN GARDEN.—After the recent heavy rains there is no kind of soil that will not be benefited by being stirred with a hoe. It is a most important operation for the well-being of every crop, and for killing the myriads of seedling weeds that so frequently put in an appearance at this period of the year. As soon as Peas have ceased bearing clear them off the ground and replant the vacant space with Broccoli, Brussels Sprouts, Cabbage, or anything else of the Brassica tribe that will be required for winter supply. Dig Potatoes at present as they are wanted, for while unripe they are best dug fresh for cooking every day. Clear all loose haulm away and level the ground as the work of digging proceeds. This should also have another crop planted on it to fill-up close as the Potatoes are dug.

The main crop of Celery must now be planted in well-manured trenches as previously advised. Where Spinach is in much request a sowing must be made very frequently, as at this season of the year it will not remain long before running into a flowering state. A sowing of Coleworts will be found useful to succeed those sown last month. Cauliflowers as they are cut should be pulled up by the roots, and the old stumps should be thrown into the refuse heap to decay. It is too often the case that if left on the ground both these and Cabbage leaves emit a most disagreeable smell. Make further sowings of Paris White Cos Lettuce, and give plenty of water to advancing crops. Frequent sowing, watering, and hoeing constitute the grand secret in procuring crisp and well-grown Lettuce. The round Cabbage varieties of Lettuce are sometimes required, especially with the chief of the cooking department. The most useful of all is undoubtedly All the Year Round. We have now for nearly a dozen years grown this Lettuce, and find our old friend as constant and true as ever.

The present is most favourable for making new plantations of Strawberries, and perhaps after all the most economical way is to layer the plants in pots as if prepared for forcing. Procure some 60-size pots, fill them with soil of a light sandy nature, place the runner on the top of the soil in these pots, and either pin with a peg or lay a moderate-size stone on the rhizome of the runner, which will be sufficient to keep it in its place until it has emitted roots. As soon as the small roots have filled the pots the plants should be replanted in a deeply dug and richly manured piece of ground. Many cultivators plant them on ground which has previously been occupied with Potatoes. Plant them 2 feet between the rows and 18 inches from plant to plant, and if established in this way early a very fair crop of the largest-sized fruit will be produced next season. There are also other methods of procuring runners which will not entail as much labour as the first one, such as allowing them to root around the parent plant, and subsequently lifting them with a fork and planting as before advised. Some cultivators plant them much closer than is here advised, and after the first year lift every other plant. Sir Joseph Paxton and President are yet favourite kinds with many, and are most prolific bearers. James Veitch, Lucas, and Her Majesty attain to a very large size, and are very good in quality. After planting should dry weather set in it will be necessary to give plenty of water in order that the plants emit roots deep into the ground and make good plump crowns by the autumn.

In the flower garden and pleasure ground there are yet many little requisites to be completed before we can feel that we may have a season of rest. Rhododendrons, Kalmias, and other American plants which have gone out of bloom require to have all the seed pods picked off. This, no doubt, is more important than it at first sight would appear, inasmuch as allowing them to remain not only gives an unsightly appearance to the shrubs, but it has the effect of seriously impairing the production of bloom for next year. Hedges of Yew, Laurel, Holly, or Privet, &c., now require clipping. The exuberant growth made will be the means of filling-up weak or hollow places. Where such is the case do not cut so close as where the hedge is matured. When the hedge is finished it should be quite level and of one continuous height. Holly, Yew, Thorn, or Privet can be cut with a pair of garden shears, but Laurel is best cut with a pruning knife, as the leaves are large and are apt to be cut in half with the shears. In quite young hedges and which have not yet grown nearly to the required height we do not advise close clipping, only merely stopping any irregularities both on the sides and tops. We have observed hedges, particularly Holly, which have had yearly merely a judicious stopping and training make good impenetrable

hedges in eight or ten years, whereas hedges that have been close shaven yearly have not been nearly so good in the same time.

Flower beds require the edges cutting neatly and the hoe lightly passed between the plants. All decayed flowers must be picked off, and all plants of a straggling habit should be regulated and pegged out in order that in a very short time the flower garden may be at its gayest, and we may reap the reward of our labours.

Roses have as a rule, considering the many disadvantages they have had to contend against, been particularly good. Heavy thunderstorms followed by a few days of real tropical weather have made very short work of all our cut-back plants. The supply has been abundant, and the new growths formed are indeed very promising for autumn supply. The light Roses have never perhaps been seen in better form. Capitaine Christy, Souvenir d'Elise, and numerous others have been seen in their finest condition, but we hope to have more to note on their qualities. Briar and other stocks are ready for budding, which may be performed now at any time at convenience; but as at present it appears there will be a difficulty in procuring buds to insert, as many varieties are making their new growths. Having your Briar stocks in readiness choose a plump shoot on which the leaves are large and perfect, and on which the side buds have not yet begun to grow. Make an incision on the shoot in which it is intended to insert the bud, using a cross cut in the form of a letter T, bind over the bud with some cotton or soft bast, and in a few weeks it will be seen that the shoot is getting firm under the tie, and before it begins to swell the ties must be cut.

WORK FOR THE WEEK.

KITCHEN GARDEN.

MAKE a sowing of Cabbage for use in spring. Hill's Incomparable, Wheeler's Imperial, Carter's Heartwell, and Wheeler's Cocoa Nut are the best for this sowing. In the south and warm localities sowing should be deferred until the 20th to 24th of this month, but in cold localities sow forthwith. They form an excellent succeeding crop to Onions. The seed should be sown rather thinly in not over-rich soil, and when the plants have a leaf or two in addition to the seed leaves prick them off 3 to 4 inches apart to keep the plants sturdy, transplanting finally early in September. A sowing may also be made of the Tripoli section of Onions, particularly for drawing early in spring, for which purpose White Lisbon is admirably adapted, being very hardy and mild in flavour. Giant Rocco, Giant Madeira, White Italian, and Neapolitan Marzaglio are fine sorts. The ground should be in good heart, especially if large bulbs are required. Sow the seed in rows a foot apart. Except in cold localities and for early use sowing should be deferred until the early part of next month. A last sowing of French Beans should be made upon a warm border. Negro Long-podded, from its enduring cold and wet better than most others, is admirably suited for this sowing. Sow also a moderate breadth of Peas of the early kinds, such as William I. and First-and-Best. If the autumn be mild they afford acceptable crops. Do not omit sowing a good breadth of Turnips—Snowball, White Stone or Six-weeks, and Golden Ball—for use in late summer and autumn. To preserve the seedlings from the ravages of the Turnip fly, dust them during the early morning with quicklime. Get out a good breadth of Cauliflower for use in early autumn. This is also the best time for planting the main crops of Broccoli, it being advisable in very rich soils to plant without digging the ground, merely pointing it over lightly with a fork to arrest the growth of weeds; in loose soils hoeing will be sufficient. Plant in rows 3 feet apart and 2 feet asunder in the rows. Continue to plant out the different descriptions of Greens for winter and spring use, the main crops of which should not longer be delayed. Plant out the late crop of Celery as soon as possible, selecting well-drained ground. Sow a good breadth of Lettuce—Hicks' Hardy White Cos, Bath Cos Sugarloaf, All the Year Round, and Neapolitan Cabbage Lettuces—for late summer and early autumn supply. Maintain the supply of Radishes by sowings as required to meet the demand, also Spinach. Do not neglect the watering of Peas, Runner and Dwarf Kidney Beans, also Cauliflower, pouring the water along both sides of the rows, affording if possible liquid manure, and then mulch the surface. It is the only way to insure a succession of tender vegetables in hot weather. Attend well to the watering of Vegetable Marrows, ridge Cucumbers, and Tomatoes, keeping the latter, whether against walls or trained to stakes, well stopped; and when a sufficiency of fruit is set stop the leading shoots, not wasting the energies of the plant in needless growths, admitting air and light also to the fruit.

HARDY FRUIT GARDEN.

Strawberries.—Runners that have been layered in pots for forcing and planting purposes must be induced by attentive watering to fill the pots with roots speedily. If they have not yet been layered lose no time in doing so. The first runners are the strongest and best, and being rooted early time is afforded them to become well established and form good crowns. Plant the runners out as soon as the roots protrude from the pots, firm-

ing the soil well about the ball and giving a good watering. Those for potting stand in a shady place for a few days, then pot them into the fruiting pots. Six-inch are sufficiently large for those required for early forcing, and 7-inch for second early and late sorts—i.e., those of robust habit, such as Sir Joseph Paxton, President, &c. The pots must be clean, placing one large crock over the hole, about three or four of lesser size, and over these a few half-inch bones, the drainage altogether being about an inch or little more. Turfy loam rather strong, adding a tenth of buffalo horn manure and a twentieth of bone dust, well mixed together but not sifted, forms an admirable compost, which should be moderately dry when used. If used wet it will shrink after potting, leaving the sides of the pot. Place the rougher parts of the compost in the pot first, and pot very firmly, and so that the base of the crown is about half an inch below the rim. Stand the pots upon a hard bottom in an open sunny situation, with sufficient space between each to allow for the full exposure of the foliage. Water as required, and overhead for a few days after potting, and when the roots are working freely in the fresh soil copious supplies will be needed, not allowing the foliage to flag for want of this essential element. Remove all runners as they appear. Plants that have been forced are excellent for forming a plantation out of doors, and should be at once planted if not already done, making the soil firm about the balls, watering liberally until established. Plants that have been fruited in pots never fail to produce good crops during the following season, often two seasons, when they are no longer profitable, and should be succeeded by more recently formed plantations.

Vines trained to walls in the open air should be kept closely nailed-in, the shoots well stopped, laterals kept very thin, stopping them at the first leaf beyond the bunch, and subsequent growths keep well pinched at each leaf as it is produced. Avoid overcrowding, training-in no more shoots than can have full exposure to light and air. This is necessary to afford any increased warmth the wall may give to the advantage of the fruit and wood in ripening. Extensions should be trained-in thinly with a view to thorough ripening.

Do not allow the shoots of Figs against walls to become overcrowded, it results only in unfruitfulness and prevents the fruit from attaining the size and quality it would otherwise attain. Stop the shoots at the sixth leaf and keep them secured to the wall, training-in extension shoots without stopping. Continue to attend to wall fruit trees in stopping or the removal of forelight and superfluous shoots, and the nailing or tying-in of the young shoots required for extension or for filling up space; and in the case of the Peach, Nectarine, and Morello Cherry shoots for next year's bearing. Some outdoor fruits are approaching ripening, and should be protected by nets from the attacks of birds.

FRUIT HOUSES.

Vines.—It is hardly possible in forcing Vines to escape early attacks of red spider; more especially is this the case when the Grapes are kept for any length of time upon the Vines after being ripe. On account of this liability of Vines to red spider we do not advise large houses with a motley assemblage of Vines for forcing, but houses only of such size as will admit of a supply of Grapes for the establishment for a period of not more than six to eight weeks. This admits of the foliage being afterwards cleansed with water from the syringe or engine; but with a house having Frontignans, Sweetwater, and Hamburgh Grapes ripe in May, Muscats in June, and late sorts in July, the dry warm air essential to the ripening of early kinds will cause red spider to increase upon the foliage of the Muscats and other late sorts before they are ripe. This is most disastrous to present and future crops of Grapes. Instead of having a mixed collection of Grapes that started in December to the new year will afford fruit from May to August, we would divide the house into two or three compartments, so that the respective kinds may have secured to them their proper treatment. In case of an attack of red spider paint the hot-water pipes with sulphur, heating them to near the boiling point. It will kill the spider, and often causes a brown spot upon the skin of Muscat and Frontignan Grapes; sulphur, therefore, applied to heated surfaces should be done with great care.

Muscats require to be ripened off with fire heat (indeed all Grapes have a superior flavour and finish when ripened off in rather dry warm air), for under no other conditions will they attain to that golden hue characteristic of richly vinous flavour. The temperature where they are ripening should be 75° to 70° by night, and 85° to 90° or 95° by day, with abundance of air. Muscats of all Grapes require very plentiful supplies of water when swelling the fruit. No Grapes can be overdone with water at the roots after the leaves are full-sized until the fruit is ripe, the border having efficient drainage, therefore attend well to the watering of inside borders, and outside also in dry weather. Keep the laterals well stopped, except in the case of weakly Vines, when they may be allowed to extend, provided the principal leaves are not crowded thereby, and in the case of young Vines a free growth of the laterals may be allowed, as it tends to root-formation and to increase the vigour of the canes.

Peaches and Nectarines.—To keep trees forced year after year in a healthy fruitful state requires considerable exactitude in the

management of the trees, not so much when the fruit is swelling and up to its arriving at maturity as after the crop is gathered. The house should then be thoroughly cleansed of insects, fumigating against thrips if any, and frequently washing the foliage with the syringe or garden engine, sparing no pains to keep the foliage clean and healthy as long as possible. The borders must be well supplied with water, the ventilation very liberal, and if the roof lights are moveable remove them altogether, which will afford the foliage the influence of Nature's refreshing dew and rains. Remove all shoots rendered useless by the removal of the fruit, keeping all gross shoots, as also side shoots, pinched or stopped to one leaf or joint, so as to equalise the sap and admit of sun and air having free access to the principal foliage. If the fruit come in more quickly than is required it may be retarded by a slight shading of tiffany or other light material in the hottest part of the day. In the latest houses where the fruit is stoning strict attention must be given to watering, and fruit taking the second swelling will be benefited by copious waterings with weak liquid manure, or, what is better, by having the borders mulched with stable manure, which attracts the roots to the surface. Attend to tying-in the shoots, stopping any laterals to one joint, and keeping the trees well syringed morning and evening. Houses without artificial heat should have ventilation early and be closed early, so as to husband the sun heat.

PLANT HOUSES.

Greenhouse.—Zonal Pelargoniums for winter flowering should have attention in shifting into larger pots, presuming that cuttings or young stock were inserted as before advised. The chief point to aim at is vigorous plants well furnished for their size, keeping off all trusses of bloom as they show, stopping the plants so as to keep them in compact form. They should have 6-inch pots, be firmly potted in good turfy loam with about a fifth of well-decayed manure and a sixth of sand. They may be placed on ashes outdoors in the full sun, taking care that they do not root through the pots, and they must be well supplied with water. Vesuvius is still one of the best, also Nyanza, Jealousy, Fire King, Sir Charles Napier, and Malcolm in scarlets; Lucy Bosworth, pink; Irene, purple magenta; Heather Bell, lilac pink; Seraph, salmon pink; and Madame Vaucher with White Clipper as whites. Of doubles—Wonderful and Dolabel in scarlets; Charles Vogt, pink; Madame Lemoine, rose; Mont Blanc and Edelweiss of whites.

Chrysanthemums when fairly rooted in the blooming pots may have liquid manure at every other watering, of which they must never need a supply without its being given, as if the plants want for water the foliage will suffer. Attend to tying out and pegging the shoots as they advance in growth. If aphids attack them dust in the evening with tobacco powder, and syringe well the following morning. If mildew is present dust with flowers of sulphur.

Roses in pots should have every encouragement to make a good growth, plunging the pots in ashes in an open situation but sheltered from winds, allowing each plant plenty of room, so that the wood may be thoroughly matured. If the plants are in small pots shift them into larger, topdress with loam and cow dung in equal parts, with a "dash" of bone dust to those that have been forced, and water with liquid manure at every alternate watering, not allowing them to suffer for want of that element. Syringe to keep down red spider, dust with tobacco powder against aphids, applying it at night and washing off the following morning, and use sulphur freely if mildew appear.

Cactuses.—Place the plants outdoors in front of a south wall on a hard bottom, and water them as required. Mesembryanthemums are best placed outside at this season; they, with Echeverias, are the better for a little weak manure water. Echeverias retusa and fulgens should have encouragement, keeping them well supplied with water and weak liquid manure, shifting the plants into larger pots if required. They are fine for winter flowering.

Azaleas.—Plants that flowered late should have every encouragement afforded them to make growth, keeping them rather close, and supply them with moisture both in the atmosphere and at the roots, affording no more shade than will prevent scorching in bright weather, for the more light the leaves are exposed to the stouter they will be, and the more mature will be the wood and buds. Keep red spider under by syringing, which will also go a long way to keep down thrips, but they can only be fully eradicated by syringing the under side of the leaves with tobacco water not too strong; or fumigation may be resorted to, doing it very carefully, as the foliage is easily injured. Plants that have set their buds should be kept in a cool well ventilated house with all the light possible, the fierce rays of the sun broken in the hottest part of the day by a slight shade, or a house with an east aspect will be a suitable structure, requiring no shading.

Heaths.—Early-flowering kinds will since flowering have made good growth, and may in warm localities be placed outdoors to ripen the wood, but in cold northerly districts they are best kept under glass, having very liberal ventilation and plenty of light. Those placed outdoors should, if the weather be bright, be placed in a shady position for a few days, such as the north side of a wall, or have a temporary screen of tiffany erected over them, as if the days be hot when they are first placed outdoors the leaves will be browned. Young plants of Heaths that were potted in

spring will be free in growth, requiring attention in stopping and training. The strong growths should be tied down or out, and the weaker ones allowed to grow upright, stopping the strong shoots so as to induce well-furnished plants. Heaths having the roots close to the sides of the pots must have some canvas or other material placed on the sun side of the pots when they are placed outdoors to preserve the roots from injury.

Withhold water from Pelargoniums past flowering, keeping them cool and airy. Cut down any plants required for early bloom, and keep them somewhat dry until they break into fresh growth. Insert cuttings, which strike freely in a close frame shaded from bright sun. Pot young plants of forcing Pinks, such as Mrs. Moore, Lady Blanche, Lord Lyons, Rubens, Newmarket, Anne Boleyn, immediately the pipings are well rooted, and grow them on, placing in frames until established, and then plunge them in ashes outdoors in an open situation, duly supplying them with water. Tree Carnations for winter blooming keep well supplied with water and liquid manure; attend also to the tying-out of the growths. Sow herbaceous Calceolaria seed in pots or pans half filled with drainage; over that the siftings of the soil, turfy loam with a third of leaf soil or old cow dung, surfacing with very fine soil, half of which should be silver sand, making even; water through a fine rose and afterwards sow the seed carefully, sprinkling very lightly with silver sand. Place the seed pan in open ground in a shady situation, covering it with a handlight and keeping it close. No sun reaching the handlight water will seldom be required, but the surface must be kept constantly moist, applying the water through a very fine rose.

Seed of Intermediate Stock (East Lothian in scarlet, purple, and white are splendid) should now be sown in light rich soil in the open ground, shading until the seedlings appear and keeping moist. Pot in September, growing-on in frames through the winter.

TO CORRESPONDENTS.

* * All correspondence should be directed either to "The Editors," or to "The Publisher." Letters addressed to Mr. Johnson or Dr. Hogg often remain unopened unavoidably. We request that no one will write privately to any of our correspondents, as doing so subjects them to unjustifiable trouble and expense.

Correspondents should not mix up on the same sheet questions relating to Gardening and those on Poultry and Bee subjects, and should never send more than two or three questions at once. All articles intended for insertion should be written on one side of the paper only. We cannot reply to questions through the post.

ADDRESS (C. C. A., Sussex).—Esdaile & Co., Wenlock Basin, Regent's Canal, City Road.

VINE LEAVES (G. McG.).—They are not diseased. The brown spots are the elevations that were produced by excessive vigour now drying up.

MATURING THE GROWTH OF PELARGONIUMS (W. J. M.).—The system to which you refer is adopted by such celebrated cultivators as Mr. Turner and Mr. James, indeed by all who grow the plants successfully. After the plants are cut down and have made a little fresh growth the whole of the old soil is shaken out, and the plants are divested of the withered roots made during the past season of growth; they are then potted in smaller pots than before, and fresh roots are emitted freely, and speedily fill the pots with roots. By no other means can such grand specimens be produced in such small pots. The fact of your plants dying is not the fault of the practice you criticise adversely, but your own fault in not carrying it out properly. We have grown thousands of plants on what you call the "desiccating system," and have certainly not lost one in a thousand. You "desiccated" your plants too much, and perhaps permitted insects to aid you in the finishing-off process.

GRAPES SHRIVELLED (Old Subscriber).—The evil is attributable to faulty ventilation, especially by air not being given sufficiently early in the morning. Leave the top ventilators open about an inch all night, and increase the ventilation immediately the temperature of the house commences rising in the morning by sun heat.

ROSES (R. Baxter).—The varieties are far too numerous to be identified from single blooms. (Constant Reader).—There are some species which require the protection of a greenhouse. Whether yours were of those species we cannot tell without more particulars.

DESTROYING WOODLICE (Baltimore).—There are various ways of destroying these pests, the most wholesale plan being to place some pieces of boiled potatoes near to the plants they infest, and cover with a little hay, and in the morning pour boiling water over the hay, so that the baits must be laid where no injury will accrue to the plants or their roots by the scalding water. Another plan is to wrap a boiled potato in a little hay very lightly, and place in a flower pot laid on its side near to where the woodlice congregate or commit their depredations, and the following morning shake the pests from the hay in which they will be secreted about the bait into a bucket of boiling water. Repeat for a time, and the pests will be reduced so as to do very little injury. In frames, pits, and houses much help is afforded by toads, they devouring great numbers; but they are not much use in houses having the plants upon shelves and stages to which they have not access.

ROSE CULTURE (Novice).—Mr. Reynolds Hole's "Book about Roses" would suit you.

INSECTS ON VERBENAS (Rus in Urbe).—They do not cause the disease, they feed on the decayed matter produced by the disease.

NAMES OF PLANTS (Clough).—It is *Gladiolus racemosus*. (C. P.).—We cannot read your *nom de plume*. *Phytolacca decandra*. (J. R. L.).—1, *Doronicum* sp.; 2, *Thalictrum aquilegifolium*; 3, *Centaurea montana*; 4, *Ran-*

unculus aconitifolius; 5, *Stanactis purpurea*; 6, *Campanula persicifolia*. (C. S.).—*Armeria latifolia*. (Jean).—1, *Iberis amara*; 2, *Campanula rapunculoides*; 3, *Veronica spicata*. (J. G.).—2, *Lonicera Caprifolium*; 3, *Tradescantia virginica*; 4, *Clematis integrifolia*; 5, *Spiræa salicifolia*? (G. N. V.).—All the same species, *Spiræa filipendula*.

THE HOME FARM:

POULTRY, PIGEON, AND BEE CHRONICLE.

MEETING OF THE ROYAL COUNTIES (HANTS & BERKS) AGRICULTURAL SOCIETY AT SOUTHAMPTON.

THIS Meeting has been held during beautiful weather and was a great success, financially to the Society, and practically to those who attended with the view of ascertaining the value of lessons which such meetings ought to teach, both as regards the latest improvements in the breed of cattle and live animals as well as that of the newest and most economical designs for agricultural implements and other appliances available for the home farm. We intend our remarks to apply on the present occasion to the live stock only, leaving the implements, &c., as a subject for a future article. We will take the stock in rotation as they stand in the Society's catalogue, and any criticisms which we may introduce will be based upon our own experience. The only object we have in view is to bring under notice of the managers of home farms, and incidentally to agriculturists generally, that which we think may tend to the improvement and practical economy of stock farming.

In referring to the stock classes we shall not weary our readers by detailing the names of the whole of the exhibitors, our object being to refer only to those who have by obtaining certain prizes enlisted our attention to certain points in the breed of animals advantageous to the managers of the home farm and gentlemen interested in agricultural pursuits.

Hampshire or West-country Downs head the list of prizes. Class 1, for the best shearling ram, first prize, Mr. A. Morrison, Fonthill House, Tisbury, Wilts; second prize, Mr. R. Coles, Warminster, Wilts. The sheep shown by Mr. Morrison in this class is so different in breed compared with second-prize sheep that we may well say there is no uniformity of type or style in these Hampshires and West-country Down sheep. The first prize is awarded to a sheep which is extremely fat, which was, no doubt, very much in its favour as regards its general outline when run out of the pens to compare with others. We therefore make no doubt it would be advisable if the Judges could divest themselves of the fatness of the stock exhibited; but the variation of type being great we can quite understand the difference of opinion which we heard expressed as to the award in this case. As far as our opinion is concerned we hold that the beau ideal of a West-country or Hampshire Down sheep is the type and style of those exhibited by the late Mr. Humphrey of Oak Ash, Chaddleworth, Berks, at the meetings of the Royal Agricultural Society at Salisbury 1857, Chester 1858, and Warwick 1859. On each of these occasions we acted as one of the Judges of sheep in the class of short-woolled sheep not South Downs, and upon each occasion Mr. Humphrey received nearly all the principal prizes, and we believe that this blood has done more to improve the Hampshire and West-country Down breed than any other; and we regret exceedingly that it is so nearly obliterated, as we firmly believe that the use of this is now the only means in case defects exist in any of the flocks of Hampshire or West-country Downs whereby these defects can be removed, if a sufficiency of well-maintained blood of Mr. Humphrey's stock can be obtained. In the case of Mr. Morrison's first-prize ram we thought that, quite irrespective of its being overfat, the wool was too deep and hollow to withstand the climate of the chalk hill districts of Wilts, Hants, Berks, or Dorset, and we therefore preferred for stock purposes the second-prize animal, as having closer wool and being firmer in flesh without being overfat, and well calculated to withstand the climate of the hill districts, and furnish to the consumer a heavier weight of flesh without any wasteful fat. In Class 2 the decision of the Judges is altered, Mr. Coles

taking the first prize, and Mr. F. R. Moore the second prize, although Mr. Morrison was an exhibitor in the class, and we thought that Mr. Coles's ram was a splendid animal in every respect, whether of colour of countenance, wool, or completeness of outline, and particularly we noticed the short full neck.

Class 3, For the best pen of five shearling ewes.—This was to our mind the most interesting and the most important class. The first prize, taken by Mr. J. Read of Hornington, Salisbury, was awarded to a pen of splendid ewes of great size, immense length, excellent colour and matching countenance, short good wool, not overfat but full of flesh; in fact we could only find one fault, that of being long and thin in the neck, and we thought how difficult it would be to correct this defect without Mr. Humphrey's stock was available in all its beauty and purity, it being so easy to correct one defect and establish another in the act of doing so. The second prize, given to Mr. Moore, we cannot object to, because they were certainly better than the commended pen belonging to Mr. T. C. Saunders of Watercombe, Dorset, who has been so successful on various occasions previously, but we thought that his sheep in this and other classes were not fed up to the mark, or perhaps he may be reserving his best fed animals for the Royal Society's Meeting at Bristol. We cannot, however, refrain from noticing the loose wool of the second-prize ewes which we have noticed in this stock at former meetings.

Class 4, For the best five shearling ewes never to have been separated from the flock till one month before the day of exhibition.—This is indeed an important contest, because a breeder may select the very choicest animals, separate them from his flock, and feed them at a heavy cost, but here we have only selections from the flock as they are, in all their native character and condition. Mr. James Read is here again to the front with very choice animals, having no defect except that of the neck as stated in the former class; and also commended for another pen.

Class 5, For the best ram lamb.—First prize to Mr. Morrison, an exceedingly fine lamb, much better in our idea than the same exhibitor's animal in class 1; second prize to Mr. A. Budd, Quidhampton, for a lamb of really good style, but not fed up to the point to bring out its merits in full. The third prize and two commendations were given to capital stock, which tended to maintain the advantage of continuing prizes for ram lambs.

Class 6, For the best five ram lambs.—First prize to Mr. Morrison. These rams were a splendid lot, well worth the attention of breeders as contradistinguished from some other flocks, although they may have descended from the stock of the late Mr. Humphrey. Second prize to Mr. Bennett of Chilmark, Salisbury; third prize to Mr. F. R. Moore. Both these are very creditable pens of animals, but the wool may be improved in both cases.

Class 7.—First prize, for five ewe lambs, given to Mr. A. Budd; a fine lot, of good style and constitution but rather thin in the neck, yet of great size and weight. Second prize to Mr. Barton; a good pen of lambs, wool not like we wish to see it, colour of face unexceptionable, necks short, and the head well set on. Taking this breed altogether they may answer well for root-feeding on the home farm, but certainly not on the pasture and park lands.

South Downs.—There were three classes (8, 9, and 10), and the exhibits were no improvement upon former shows; yet the animals exhibited were highly creditable to the breeders, especially the shearling ewes shown by Major-General Fitzwigram, Bart., of Leigh Park, Havant, which were capital specimens of the breed, and well adapted for furnishing mutton of the highest quality to the owners of home farms generally in the southern and south-eastern counties.

Oxford Downs.—These are the most important cross-bred animals—that is to say, of recent introduction; and although in the western districts of the kingdom the Shropshire Downs may be better for that soil and climate, yet the Oxford Downs in the midland counties are the most valuable of the black-faced stock and are much esteemed by the originators of the cross derived from the Cotswold and Hampshire. There are two classes of this breed exhibited, and they contain very large animals of excellent quality and yielding heavy fleeces of valuable wool, especially the shearling ewes, the first prize in each class being taken by Mr. Adams of Pidwell, Farringdon. These ewes are stock of great merit, and we think far superior to the shearling rams; they are so matching for colour of face, size, and quality of wool, which we have never seen surpassed as Oxford Downs. The second prize for shearling ewes is taken by Mr. Wallis, an old name as exhibitor in former seasons, but his stock on this occasion is anything but matching; the difference in the wool is very much against them, although they are heavy well-bred stock.

Long-woolled Sheep.—Class 14, for shearling rams. This was a grand class. The first-prize animal, belonging to Mr. R. Swanwick, is a gigantic specimen of the Cotswold breed, with beautiful and abundant wool, and flesh of excellent quality for this sort of sheep. Messrs. Gillett's second-prize sheep is but little behind the first-prize in merit.

Class 15, Rams of any age.—Mr. R. Swanwick is again to the fore with a magnificent sheep of extraordinary weight for age. Second prize goes to Mr. Raynbird of Basingstoke for a grand animal, and thereby being placed before the Messrs. Gillett.

Class 16, The best shearling ewes.—Messrs. Gillett take this prize with an admirable pen of ewes and worthy of their former fame. We, however, should like to see them with darker grey faces, as these sheep are now so much used for crossing with the Hampshire and other down breeds. This matter is of some importance, and by careful attention it may be obtained without depreciation of the breed in other respects. We have extended our remarks upon the long-woolled sheep desiring to call attention to the long-woolled breeds generally, including not only Cotswolds but Leicesters and Lincolns. Each of them, being stock of a quiet habit of feeding, are admirably adapted to graze with the ornamental cattle usually kept in the parks and home pastures of landed proprietors.

(To be continued.)

WORK ON THE HOME FARM.

Horse Labour.—The mangold should now be horse-hoed the last time where early sown, but the season for drilling was so much delayed by wet weather in May and June that a large portion of the crop is now only being horse-hoed the first time. The early-sown Swedes may now be horse-hoed, also the cabbages and carrots. It is rather early for setting-out or hand-hoeing the carrots; we prefer to hand-pull them where sufficient labour can be found, as the young-pulled plants furnish good food for stock. The horses are employed cultivating for turnips, and where there is any couch grass, instead of whole ploughing, we prefer to rafter or half plough, then scarify across the rafter two or three times; this will keep the grass at top, which can be then more readily separated from the land in the act of rolling, harrowing, &c. The morning part of the day may be occupied by turnip tillage, the afternoon by hay-carting and stacking of the meadow or pasture produce. The horses may now, where the land has been cleared of the hay, be employed by carting dung and earthy composts on to the pasture; and if the compost has been properly treated by turning and mixing this is the best time to dress the pastures, and a few days after the manure is spread it should be chain-harrowed, in order that it may be worked into the land, so that the grass may be immediately benefited by the dressing. The odd horse is still constantly employed in carting materials for feeding the horses, the fattening cattle, the pigs, and the shepherd will also require hurdles removed on changing the pasturage or in the feeding-off green crops, such as vetches.

Hand Labour will now consist of hoeing and setting-out mangold, Swedes, &c. Trimming the hedges, too, will be going on when wet weather stops the hoeing, and it is important that the quick-set fences should be trimmed early before the shoots get hard, because if it is deferred until after the harvest we have found the hard points of the quick injure the feet of the sheep, and when these points enter the bottom of the foot it is a serious matter for sheep, as they often suffer and go lame for a long time.

Farm labourers are more scarce than they used to be, and are more difficult to manage, requiring more pay and doing less work than formerly; it is therefore an important arrangement to have as much of the work of the home farm done by the piece, such as hoeing at per acre, hedge-trimming at per score rods, &c. Thatching of ricks is more difficult than ever to get done at the time required, as thatchers are sort of journeymen going about here and there, and, as they are required, from farm to farm. It is, however, best to have a man who can thatch as a constant workman on the farm; this is easily done, or used to be. We have for many years put some of the most willing and industrious men to thatch the ricks. At first we have known them say they could not do it; as, however, thatchers receive good pay we have found that the prospect of extra wages has induced them to learn the work, and for a series of years we have instructed a number of young men, or at least put them to this work, and they have in various instances become excellent rick-builders, thatchers, &c.

There is, however, unfortunately, less disposition on the part of the labourer to remain in constant work on a farm than there ever was before, and it is this roaming disposition and desire for change which makes the labour question so difficult. We therefore, in order to provide a sufficiency of men on the home farm, advise that enough cottages should be built to locate the men, and unless this is done serious impediments will occur in the labour of the farm, and at the most important time. The labourers, if possible, should be selected as well-conducted men with industrious wives and families, so that women's and boys' labour may be available on the farm. If this matter is neglected, and no women or boys are ready for work on the home farm, where decency and the tidy appearance of everything about the premises is so important, it is almost impossible that it can be effected unless the necessary work be done by men at a heavy cost, and under such circumstances we have found in home-farm management it is impossible to show a profitable and economical account.

MANAGEMENT OF YOUNG POULTRY IN SUMMER.

WE have tried through the various seasons to follow the growth of young poultry, and to point out the special difficulties or infirmities to be guarded against in each stage. It is often thought

and said that when the warm weather comes then the young stock will look after themselves, and that little further care need be taken. This is an error, which, like most other errors, contains a certain amount of truth. It is true, of course, that the hazards from damp and cold winds are past, the delicate season of feathering through which young birds are apt to be dainty and pine is generally over, and a period which should be one of constant hearty appetite and rapid development has succeeded. There are, however, many little things to be attended to in hot weather such as we have had of late. Disease is most easily generated during heat and drought, and seems then peculiarly fatal and infectious. The most frequent and certain source of it is want of ventilation in poultry houses. We suspect that few people have an idea of the suffering endured by fowls through hot nights in ill-ventilated houses and coops. A closed coop with an air hole or two in front does well enough for a hen and brood in February or March (for our own part we should even then prefer a greater amount of ventilation), therefore it is thought the same coop must suit the half-grown brood in June or July. Only let the master or mistress open it some morning and investigate the state of the air within! For old birds and young alike thorough ventilation is now absolutely needed. If possible the doors of all houses should be left open all night. It is the nature of birds to rise early, and insect provender may be found through the early hours in dewy grass which is not procurable later. Where, however, it is impossible to pursue this plan—i.e., where thieves are feared, or the bird's range is too extended for it to be safe for them to wander at large before people are about—there must be thorough ventilation through the houses over their heads.

A large number of our own young poultry roost in trees through the summer, indeed our Turkeys do so at all seasons. Trees are their most natural abode, and we always find them do best there. Of course some risk is run, but we prefer now and then losing a bird through some accident to boxing all up in houses. They become very hardy, and by the autumn their numbers are so thinned by constant weeding that the select few are easily and comfortably accommodated in half the number of houses that would be required if all had to be housed at midsummer.

Coops, too, must be ventilated—i.e., their fronts should never shut up to the top, or nearly so. If they are constructed with a weather board to protect the open part fresh air can always get in, but wet cannot. In settled fine weather a piece of wire netting in front is even preferable to any boarding at night. They must, of course, be opened very early in the morning. We find small moveable houses, about six times the size of coops and without bottoms, capital contrivances to succeed coops. They are at first placed where the coop has last been with open door, and the broods soon take to them. They are moved from day to day, and need no cleaning, for grass land is immensely benefited by this gradual process of manuring.

Diet, too, should be changed in heat. The fare of a native of Hindostan is very different from that of a Laplander, and for physical reasons; we should for the same vary our own and our bird's diet with the temperature. Rice (boiled) and the less substantial meals will now make a good change, and for grain *dari* in lieu of wheat; but above all cool water is of the greatest importance. Not only should all water vessels be emptied and refilled morning and evening, but they must be placed in the shade. Heated water is most prejudicial. It will be found to keep purer and cooler now in deep pans than in the shallow ones used for very young broods.

We have, of course, been speaking about the treatment of early-hatched birds now half grown. In establishments where a regular succession of chickens for the table is required there will still be young broods; these, strange though it may seem, are by no means so easily reared now as earlier in the season. Country people have an old saying about the delicacy of "blackberry chickens;" this probably means chickens hatched during the parching heat accompanied by east winds which we often have when blackberries are ripe. If similar weather comes in June or July the effects are like on newly-hatched chickens; they seem to wither up, refuse their proper food, and rush with unnatural cravings at dried leaves and bits of sticks. We do not pretend entirely to account for this, but fancy it is due to exhaustion analogous to sunstroke, and to dryness of the ground, which does not afford insect food. The coops should, if possible, be put in moist places among trees, and the soil round them watered; a little meat chopped fine should be given to the broods, and some iron tonic mixed with their water. At times all remedies fail, and in yards where, as a rule, nineteen out of twenty April or May chickens are reared whole broods in the summer go off at from ten days to a fortnight old; this, however, generally happens where disease has begun before any care has been taken, and is rarely the case in well-ordered establishments.—C.

VARIETIES.

WE are informed that at the Royal Agricultural Society's Show at Bristol this week Messrs. Sutton & Sons of Reading will exhibit their interesting museum of vegetable products, which will

occupy a space of 130 feet in length. It will include, among many other objects, 250 dried specimens of natural grasses, models of their Champion Swede, collections of mangolds of the growth of 1877, showing its valuable keeping properties; models of different vegetables, collections of 1300 different kinds of vegetable and flower seeds, and an exhibition of valuable silver cups given as prizes, and of the value of £500.

—THE seed farms of Messrs. Webb at Kinver, Staffordshire, were visited on Tuesday, the 2nd inst., by the Midland Farmers' Club, on the invitation of the proprietors. Messrs. Webb's Royal Seed Establishment at Wordesley, Stourbridge, is well known to agriculturists from the annual root shows held there each autumn; but the extensive seed farms of the firm, lying more out of the line of general traffic, are perhaps less well known, except by repute, to those interested in farming matters. Mr. William G. Webb and Mr. Edward Webb received the party with unstinted hospitality. The farms the visitors had come out to see are the largest seed farms in the kingdom, being altogether 1100 acres in extent—Kinver Hill farm, 400 acres; Dunsley Manor farm, 250 acres; Kinver Edge farm, 300 acres; and High Grove farm, 150 acres. Although this represents a large area for seed-growing purposes, it is in reality but a fractional part of the acreage Messrs. Webb employ. The Kinver Hill farm is in great part used only for trial and experimental purposes and for growing stock seeds of selected varieties, to be multiplied afterwards in different parts of the kingdom in quantity sufficient to meet the demands of a rapidly expanding business.

—THERE is one point in poultry management to which we wish to call especial attention, as but few persons who rear poultry for profit ever attach much importance, notwithstanding it has a great influence upon the profits. It is to keep your birds tame, whether they are kept up in suitable enclosure during the entire year, or permitted to have unlimited range, for it pays to do so in many ways. If you keep your birds tame, so they will come to you quickly at the call and eat out of your hand without any sign of fear or distrust; they will always be quiet and content, and will fatten and thrive much better. This matter is well understood by breeders of the larger kinds of stock, such as cattle, horses, sheep, and swine, while there are a sensible few who apply the same principle with poultry. Many a fine nest of eggs has been destroyed by a wild and frightened hen, a hen which had early learned to fear her master or owner. If uniform kindness and gentleness had been resorted to, the hen would suffer herself to be handled while on the nest, and never once think of leaving it in such a hurry as to endanger the eggs. If the poultry on the farm is kept tame, it is not a very difficult matter to catch one or more when wanted for table or other uses.—(*American Poultry Journal*.)

—THE Director of the model farm at Hubandiers, France, M. V. Nanquette, has published a communication on the subject of his experiments in feeding with Jerusalem artichokes. A twelve-years experience has convinced him of the great value of this vegetable as food for horses and foals. Some 6 or 8 lbs. a day, in conjunction with oats and hay, form a most readily digestible ration, as shown by the results of the experiments, and they also improve the general health, while being of special service in promoting a brilliant coat.

—FOR the four weeks which ended on June 17th the beef supplies from America for British markets exceeded 5700 live bullocks and 8000 carcasses, or 32,000 quarters. Mr. Timothy C. Eastman is said to have been the pioneer in this business. He began his first shipment of fresh beef from America to England in 1875, and the lot consisted of forty-five cattle and fifty sheep. At the close of 1876 and at the beginning of 1877 his shipments, mostly from New York, were from six hundred to a thousand head of cattle per week. He has shipped about sixty thousand head in all, having opened markets in London, Manchester, Liverpool, Sheffield, Birmingham, Leeds, Newcastle, Glasgow, Edinburgh, Dundee, and other towns in this country.

PASTURAGE OF BEES.

As a sequel to the conversational letter on this subject which has appeared in the Journal, we shall now notice some of the bee flowers that are considered of secondary importance, and begin with those that flower in spring.

The flowers of crocuses, osiers, and willows are much haunted by bees. These flowers yield much pollen and probably a small portion of honey. Hyacinths that ornament and perfume our flower gardens in early spring contain much honey, and the bee is in taking it from them scratch and disfigure their petals. Single wallflowers, apricots, peach, and almond trees are excellent honey plants, but it is only in warm and protected places in this country that apricots and peaches are grown. Bilberry bushes that cover much of some moorland districts like heather, are honey plants in the highest grade, but as they flower early in districts where few bees are kept very little honey is gathered from them. I guess the honey of bilberry flowers is strong-flavoured like that of heather.

All the cabbage, kale, and turnip tribe of plants have cruciform flowers, like those of ketlock or field mustard, and yield a great deal of honey and pollen. Probably the honey from the cabbage tribe is, like that of field mustard, not of the highest quality in flavour.

Maples, laurels, gorse, broom, and snowberry are all honey plants; but gorse and broom belong to the fourth or fifth grade of honey plants. However, they yield pollen enough to send our bees home besmeared with it yellow as soldiers.

Lotus corniculatus, called yellow clover in Scotland, is a capital plant for honey. It is found in some districts of poor soil, and on roadsides in great abundance. It continues a long time in flower, and is very attractive to bees. I imagine the honey from this is superexcellent. Amongst the garden annuals that yield honey a place and good name are given to borage, poppy, *Centaurea cyanus* (bluebottle), and mignonette, especially mignonette.

Wild thyme which grows plentifully in some parts of some southern counties of England, North Wales, and Wigtownshire in Scotland, is a grand plant for bees, for it yields the highest quality of honey. Buckwheat is sometimes sown in patches about the woods of noblemen's places in England for pheasants. It is extensively grown in America, and in the apiarian world there it takes the place of our heather. Bees are fond of it everywhere, but the honey from it is said to be strong-tasted. The American willow (*Epilobium angustifolium*), which is often seen in cottage gardens and in shrubberies about gentlemen's gardens, is one of the best honey plants known. An acre of it would be a "Lake Superior" indeed for bees. Many more honey and pollen plants could be named, but as they are scarce in some districts, unknown in others, not plentiful anywhere, their enumeration here is unnecessary. I have seen bees working on the hawthorn, the field daisy, the common buttercup, the dock, and the dandelion, but I dare not say that honey can be found in the flowers of these plants.

No two kinds of plants yield honey alike in flavour, or pollen alike in colour.

Let me now congratulate the bee-keepers of Great Britain on the favourable change that has taken place in the weather. Since the 22nd of last month both wind and weather have been very favourable for honey-gathering. If this weather continue for two or three weeks the year 1878 will be a remarkable one for heavy hives. Let all the empty supers be put in use, and all the honey jars be got ready.—A. PETTIGREW.

BEEES IN THE NORTH.

MR. PETTIGREW'S contributions are interesting, but I should like to see letters from other parts of England giving the experience of those who use large hives.

I mentioned in a former letter that I started in the spring of 1877 with three very small hives. I had three first swarms which I put into 18-inch hives, and two second swarms which I put into 12-inch skeps. All my hives lived through the winter, but one, a small old one, died in May with 14 lbs. of honey in the hive. The three top swarms in the 18-inch hives were not filled; one which was swarmed on the 27th June, 1877, was not half full, but strange to say it weighs now 55 lbs., after having sent off a swarm on the 26th. The others are quite full, but as I am going from home and it is late I am trying to prevent swarming. I have put on ekes and supers, in which they are working as only large stocks in large hives can do.

I want more particularly to let Mr. Pettigrew and others know about an 18-inch hive which last September I populated with the bees of two or three people who intended to "smoor" (suffocate) them with brimstone. These were six small swarms; I fed with syrup according to instructions, but they only about one-quarter filled the hive, and I was afraid they would not winter, and as this spring has been very unfavourable I have fed frequently but not largely with this result:—Hive, board, honey, and small super weigh 65 lbs., and as I write they will be 70 lbs., for I weighed it last evening. I weighed it first on the 18th of June, when it was 34 lbs., hive and board included; 19th, 36 lbs.; 20th, 37 lbs.; 23rd, 43 lbs.; 25th, 49 lbs.; 29th, 65 lbs.

I put an eke on last night to prevent, if possible, swarming; not that I object to swarms if they come before the 15th of June, but my hives not being full to begin with, and a wretched wet spring, they have had little chance with small hives; but even those in this part have in few cases thrown off swarms till within a week or so. Our honey season is only commencing. I have done some artificial swarming with small stocks with complete success.

If some of your correspondents would give results of large hives well managed I feel sure many others would be glad besides.—HARDY OF THE HILLS, Northumberland.

OUR LETTER BOX.

HENS UNMATED (T. M.).—Hens lay perfectly well if kept without a cock, almost as well as with one. We know many amateurs who live in towns who never keep one, but when the opportunity occurs they borrow one for a few

hours. This is easily done, and where it is not intended to hatch chickens the breed is unimportant. Any will do. We do not think it any advantage to keep the cock between this and the middle of December. We speak, of course, of eggs intended only for the table.

FULL HIVE (Comber).—As your hive has filled a large eke and is very strong it should be either supered or swarmed at once. If you resolve to super it first, cut a good large piece of white comb out of the side of the hive and fasten it in the super before it is put on. The piece of comb will tempt the bees to enter the super and commence work. The super should be large enough to give room for the bees and hold 20 lbs. of honeycomb. If you resolve to take a swarm instead of using a super, put the swarm in a small or 16-inch hive, which will be easily filled and made into a good stock. If you want honey this year your better way will be to super. If you want an increase of stocks swarm the hive artificially, and encourage both swarm and stock to breed well at the end of this season.

WAX-PRODUCING BEES (Mrs. D.).—The white scales or flakes seen on the bodies of the bees you have sent are pure wax, produced and excreted in the natural way, but in far greater abundance than we have ever seen before. Bees building combs secrete wax, and the secretion is excreted and appears on the under sides of their bellies. Two flakes at a time are usually produced by a bee, and are extruded at one of the rings of the abdomen; but in your case four and six flakes appear at the same time, all apparently perfect, though some of them are extruded at the last ring of the abdomen, even up to the point. This superabundant production of wax is certainly abnormal and wonderful, but as the bees are quite healthy you have nothing to fear. The other hives will not be affected or hurt in any way by the wax-producing hive. The fact that the board of the hive is covered with flakes of wax is not to be wondered at, for bees that produce two flakes only at a time drop many on their boards, but where six are produced instead of two many more will be lost in the process of comb-building. We are obliged by your interesting letter.

REMARKS.

3rd.—Dull showery morning; fine and bright after 3 P.M.; cool evening.
4th.—Fine day; heavy clouds and stormy-looking evening; starlight night.
5th.—Dull morning; fine afternoon and evening.
6th.—Fair but dull morning, bright sunny afternoon; cloudy evening.
7th.—Fine day with pleasant breeze, at times stormy-looking; dull evening, few drops of rain at 8 P.M.
8th.—Fine pleasant day; moonlight evening.
9th.—Fine sunny morning, gusty wind; very cloudy afternoon; slight rain in evening.
Cold in night between 3rd and 4th, otherwise an uneventful week.—G. J. SIMONS.

COVENT GARDEN MARKET.—JULY 10.

OUR market has been very lively this last week.

From observations taken near London during forty-three years, the average day temperature of the week is 73.2°; and its night temperature 51.1°.

HINTS ON LANDSCAPE GARDENING.—No. 6.
THE SITE OF A HOUSE.

LANTING is so much interwoven with almost every part of landscape gardening, that before proceeding to treat of the formation and arrangement of trees and shrubs in clumps, belts, and beds, some common starting point should be chosen.

The residence suggests itself as the most suitable object for our purpose, and we will first turn our attention to the selection of its site. In doing so we must not forget the importance of shelter, of an abundant supply of pure water, of a pleasant view of rich natural scenery, and of access to the house.

Fondness of a fine view frequently induces forgetfulness of the water supply and shelter till the building is finished and it is too late. I will give an example by way of illustration.

Upon a range of hills some 600 or 700 feet above the sea level, commanding a pleasant landscape, widespread, and with another still more lofty range of hills broken into numerous peaks and undulating ridges in the distance, two gentlemen decided to build their houses; one placed his out upon the topmost plateau exposed to every wind that blows, overlooking miles of country, with all the distant hills fully in view, and with a water supply entirely dependant upon wells and pumps: The other gentleman, with sound judgment and excellent taste, chose a site upon the side of a sunny slope open to the south, but with high land sweeping boldly upwards upon either hand from the south-west and south-east to the northern ridge behind in the form of an irregular semicircle, affording shelter from cold winds in spring and from south-western gales at all seasons of the year, to which advantages subsequent planting gave a complete finish, and formed a snug, cosy, home-like air, which the more exposed house never could possess. Thus the house was shut in on every side but the south, where there lay before it a view of great beauty and richness—just a choice bit of the more extensive scenery to be enjoyed by climbing the hill behind the house, and with only a few hill peaks and ridges in sight, but which undoubtedly gained in effect from their isolation. An abundant supply of pure water was obtained from a spring flowing from the north hill about 100 feet above the level of the site of the house, so that by means of a reservoir and piping it was conveyed to cisterns at the top of the house and distributed about the garden and among the outbuildings without artificial force of any kind. Fountains, too, were introduced at various points at a comparatively trifling cost, and thus every natural advantage was seized upon and turned to account.

In a hilly country such situations are by no means scarce. Many a fine position for a house have I seen lying waste in various parts of England, notably in the home counties of Kent, Sussex, and Surrey; and also in Derbyshire, Devonshire, and Cornwall, and, oddly enough, it is not uncommon to find such positions overlooked and houses built in all

sorts of incongruous positions. Three examples occur to me now. The first is an estate near the east coast, with a very undulating surface forming an irregular series of hills and valleys, one central eminence commanding the estuary of a river alive with shipping on one side and a picturesque wooded valley running inland on another, and yet the house is built in a low, damp, unwholesome situation shut in by trees, and with its principal front facing the north! The house is an old one, and one can only account for its odd situation by supposing that its builders sought shelter and proximity to a public road, the making of good private roads being then a matter of greater difficulty than it is now.

The second house, a large massive structure, illustrates another extreme, for it has no shelter of any kind, but crowns an eminence in the centre of a park, and certainly commands views of some of the best park scenery in England; yet it is undoubtedly a mistake, the park containing a much finer situation, more elevated, and near the upper end of a valley, turf-clad, and with gentle widespread slopes ascending gradually to well-timbered heights, where magnificent old Oaks cluster together in clumps and stretch their gigantic arms alongside cool fernery glades. Majestic trees of uncommon size also shut in the head of the valley, and from thence one has a view of singular richness—downwards over wide sweeps of turf agreeably broken by equally fine masses of timber, across the waters of a lake with glimpses of its winding shores half hidden among the trees at other points, onwards over some miles of well-timbered country beyond the park to a lofty range of hills in the distance.

My third example is an equally fine structure upon an elevated and tolerably well sheltered position in a park which it overlooks to its farthest boundaries, with just a glimpse of water and a winding shore which invites us to explore, and upon doing so we come upon a sunny sheltered slope commanding a view of an estuary with winding shores densely wooded to the water's edge, so beautiful that we are lost in wonder that advantage had not been taken of so fine a site, infinitely superior in every way to that whereon the house stands.

When there are no uplands, and the surrounding country is flat and monotonous, we should select a site overlooking fine timber, or a space which may be made ornamental by judicious planting as well as by breaking up certain portions of the surface, not for the formation of a series of trivial mounds and ridges as for the production of a bold and picturesque effect, such as we have in an excavation for a piece of water with high-raised banks, and with a miniature dell leading down to it, also formed by excavations. Let it not be supposed, however, that I wish to imply that level spaces cannot be rendered ornamental without being broken up. There is so much beauty in the soft fresh turf of this country, that one desires few more pleasant sights from the windows of a house than a turfey expanse well timbered with clumps, glades, and solitary specimens of ornamental trees. Combined with the repose of such a scene we have dignity, refinement, and ample life and variety; for it is idle to talk of tameness in the

presence of fine trees when they are arranged with skill and taste.—EDWARD LUCKHURST.

WINDOW GARDENING AND WINDOW PLANTS.

(Concluded from page 3.)

SOIL.—Seedlings, such as annuals hardy and half-hardy, once started may be, and are generally, grown in the open beds or borders, and will grow in almost any soil except it is wet and undrained or too sandy or peaty, in which case nothing will thrive. Most people have a bit of garden of some kind, and if in towns a patch often before their doors, for a small border or flower bed. In all such cases a few barrows of prepared soil would be most desirable. The prepared soil might consist of loam. In towns it would be worth the cost, if you are not experienced, to procure it from a nurseryman, as loam is indispensable for general potting purposes also; the best substitutes for good loam is dry cow manure procured in summer in cakes and torn asunder, or leaf mould one or two years old. With a sufficient quantity of these three to mix as may be desirable, some peat for the use of fine-rooted plants, some sand for general purposes (to be used cautiously, as it is cold, and most soils contain a sufficiency of silica for early elaboration), some lime to strew in the way of slugs, &c.; some soot to use with the watering when a deep rich tint is desirable. The proportion in which those soils should be mixed for different plants and how used can be readily ascertained by a cursory look through the "Garden Manual" or the "Window Gardening" handbook, published at the office of the *Journal of Horticulture* and obtained for a few pence, and into which the limits of those observations do not permit me further to enter.

POTTING.—If the pots are new steep them until they cease to effervesce, and then put them to dry. If they are old they should be thoroughly washed, and to make them look like new take a piece of a pot and in the washing scrape the sides of dirt or green slimy formation with it. Speaking generally broken potsherds are best for drainage covered by moss, short straws, or the fibre of loam to prevent sand or clay being washed through. Instead of potsherds, and often more convenient, you can use small granulated, not too small, charcoal, which the roots may be often observed twined around, and from which they take in carbonates; over these the coarser part of your soil, and the finer portions for the surface; but for a growing plant, seedling or cutting, the more open the soil is, especially with amateurs, the greater the certainty of success. Any soil in which a sufficiency of water does not readily pass away is unsuitable, and will but bring disappointment. Next in order, and first in importance, towards success is

WATERING.—If you have reason to think the soil is moderately moist, and that your plant is not thoroughly established as a young seedling, if the flagging occurs through sun heat, shade rather than water. If an old plant watering will not do harm at any time, but in most cases in summer the evening or early morning is more desirable. In winter little watering is necessary as a rule for window plants at any time, as in most cases, except bulbs and essentially winter plants, growth should not be encouraged. Nothing is more undesirable than watering by routine. You may examine your plants morning, noon, or night, but you must not water by any means so systematically. The necessity for watering at all depends very much on the action of the sun. Well, during the month of June, up to the 18th we had not one day's warm sunshine, and instead of the thermometer standing at 80° it did not, as I remember, once exceed 60° in the shade. During the past week alone the rainfall exceeded 2½ inches. Need I say for outdoor plants watering was wholly unnecessary, and owing to the humid state of the atmosphere, and consequent non-evaporation, watering for window plants was also almost undesirable? Now, if this is so in June, the same principle of atmospheric observation must very much guide you at other times in your waterings. Great heat will produce evaporation or perspiration from your flower pots or flower leaves, and this must be returned some way. Watering is not always the best way to do it. Syringing the plants, the glass, or the flagging of the floors produces a moist atmosphere in a greenhouse in hot weather, and the more nearly window gardeners can imitate this the better. I have grown Balsams beautifully shrubby and healthy in a window by closing during warm sunshine and taking a bunch of feathers and some soft rain water and lightly showering it on the leaves and around, thus creating a moist atmosphere around the plants, which, owing to having plenty of air and their dry situation, were prevented from

being shanky or drawn. I mention this as an illustration. There is less necessity for a moist atmosphere in most other cases, as this moist atmosphere, uninterrupted growth, and plenty of hot room is for them a necessity for success. A few words how one may generally know when their plants want watering: For small plants after a little experience you can absolutely know by the weight of the pot. Generally you know by appearances, but to this there are many exceptions; for instance, a dry March north-east wind will leave the surface as dry as ashes in one half hour, but the roots may want no water—in fact if cold it would be injurious. By striking the knuckles against the side of the pot—this is the plan adopted with large pots that cannot easily be raised or weighed on the hand; and lastly, even though the surface may appear dry, should the soil effervesce on the application of water nothing but a regular plunging in a vessel of water will be sufficient. As to what water is most desirable—Soft water is much to be preferred; chills are avoided, and a French *savant* published some experiments to show that in absorption hard water had a caustic effect on the spongioles and minute rootlets, while rain water exposed to the sun appeared to have a soothing effect as well as an evident stimulus to elaboration. This seems reasonable, and were plants treated as living organisms, subject to many of the climatic vicissitudes that affect human beings, and were it remembered they are circulated by sap as our frames are by blood, and with many other peculiarities in common, it might be hoped a more intelligent interest would be taken in their welfare, errors in the treatment of which often arise from a want of knowledge to do better. To those who love plants—and who will not plead guilty to the soft impeachment?—there is no sorer sight than a dying waterlogged beautiful plant incapable of effecting its own cure. Therefore keep a vessel for rain water, and expose it to the sun and air to make it warm and soft. Little watering is necessary except in a warm sitting room during the winter months, and then use water of the temperature of your room by leaving it one side of a fire or on a boiler until the cold is gone out of it. If you cannot have rain water you can soften spring water, by boiling and subsequent cooling, by the addition of carbonate of soda or potash, though I must confess my dislike of those latter means as compared with the other.

Manure Waterings.—I have always been of the opinion this is too little resorted to. Window gardeners must generally use small plants and small pots. This is principally because their space is limited and because they love variety, and it can hardly be denied that a neat, compact, well-grown little plant is much more to be preferred than an unduly forced and consequent short-lived larger one. This can be even better done by an intelligent study of how liquid manure can be advantageously applied and used in preference to a large body of earth with loss of space and loss of variety. As a rule sheep droppings, cow manure, guanos, or phosphates, &c., can be had inexpensively—and the two first in the country for gathering—and must be used weak and clear. It should, however, be frequently used for plants in robust health in small pots, and still more so towards the time of the expansion of the flower blooms. An intelligent use of manure waterings will save much trouble in repotting, will keep your plants in rude health, and if soot is sparingly used with it will give a tint and finish to the foliage and bloom that well repays the trouble. A sponge to wipe up what passes through as surplus, and some dry dust as a deodoriser, will facilitate its use in the costliest of drawing-rooms, and render it unobjectionable either to the olfactory nerves or superior taste. A small tank in the ground that takes up little space, and that may be furnished with a cover, and into which you may throw slops occasionally, with the horse, cow, or sheep droppings to be often had for nothing, is all that is necessary; only when the supply begins to fail should it be stirred.

INSECTS.—I grow hundreds of plants, most of them suitable for windows, and rarely ever see an insect. I attribute this to providing them with a suitable atmosphere both as to air and temperature, and cautious and careful watering—I say cautious watering, for invariably a water-sodden sickly plant will be covered with green fly and communicate them to its neighbours. When one appears immediately remove it and syringe or wash. Some have small conveniences for fumigation, but remember precaution is better than cure. A healthy well-grown plant will seldom give any trouble that way; if it does a syringing with a diluted solution of tobacco water will effect a perfect cure either of green fly, thrip, red spider (which I have never seen on a window plant), &c. Calceolarias, Cine-

riars, Primulas, and Pelargoniums are the gems of window plants, and subject to green fly. To avoid the possibility of this grow them slowly onwards to a certain stage in moist pits or frames, and insects will give you no trouble. Mice and other vermin care little for plants, and will disappear if nothing is left in their way upon which they usually feed.

Were the limits of this article not already exceeded I should feel bound to separately notice such necessary operations to be borne in mind as cleanliness, washing and syringing; respiration, perspiration, or evaporation; shifting, light and shade, &c.; but there is the less necessity for this, as the several points have been cursorily referred to in connection with other points as we proceeded. It now remains to mention some window plants, which with very limited means I have myself successfully grown and flowered during the past twelve months without the use of any extra appliance but a pit with some hotbed manure to start seeds and cuttings in early spring:—

1, *Indispensable Window Plants*.—Calceolarias, Cinerarias, Fuchsias, *Primula sinensis*, Petunia, and Verbena.

2, *Very Desirable Plants*.—Abutilon, Acacias, Ageratum, Amaryllis, Balsams, Bouvardias, Cuphea, Coronilla, Camellias, and Citrus family, Daphnes, *Deutzia gracilis* and the double variety, *Dielytra*, Epacris and Ericas, Gazania, Hydrangeas, Heliotropes, Justicia (I have one in flower at present in a window), Lilies, Myrtles, Richardias or the Nile Lily, Salvias red and blue, Tree Carnations, &c.

3, *Plants that with Care do better Outside*.—Antirrhinum, Auricula, Asters, Anemones, Chrysanthemum, double Primroses and double Rockets, Marigolds, Mimulus, Polyanthus, Portulaca, Pentstemon, Phloxes, Ranunculus, Sweet William, Stocks, Zinnias, &c.

4, *Creepers and Climbers*.—These are for sides of windows or trailing along sides of boxes.—*Cobaea scandens*, *Dianthus Heddwigii*, Ipomeas or *Convolvulus major*, Lobelias, Sweet Peas, *Tropæolums*, while *Saponaria* and *Nemophila insignis* make nice edgings.

5, *Sweet-smelling*.—Musk, Mignonette, Violets, Wallflowers, &c.

6, *Bulbs*.—Crocus, Hyacinths, Gladiolus, Ixias, Sparaxis, and Tritonias, Tulips, with such handsome things as *Tigridia*, *Scilla*, *Babiana*, &c.

7, *Succulents*.—Aloes, Cactus, Crassula, Sedums, &c.

8, *Tender Plants*.—With a little bottom heat to start with you can readily, as I have at present, tuberous Begonias, Celosias, Achimenes, Gesneras, and Gloxinias. If the three last mentioned never flowered the foliage would be "a thing of beauty" itself, which Shakespeare calls "a joy for ever."
—W. J. M., *Clonmel*.

GRAPES WITHOUT FIRE HEAT.

THIS subject, mooted by "A KITCHEN GARDENER," criticised by Mr. David Thomson, and reviewed by "NORTH LINCOLN," is one of very great importance. Gardeners know tolerably well that excellent Grapes can be ripened without fire heat over the greater portion of England. In the extreme north of the island it is not expected they will so ripen, but let not this fact deter those residing in more sunny and favoured districts from erecting vineries from the fear of incurring after and permanent cost by the purchase of fuel.

I can confirm what has been said by your correspondent, on page 22, as to Grapes ripening in Lincolnshire without fire heat. I have seen splendid Grapes produced in that county where the heat has been wholly supplied by the sun.

The means of heating a vinery is, as has been suggested, undoubtedly valuable, especially for protecting plants in winter. But even that is not always an advantage in the case of amateurs, who are sometimes rather fond of "playing with fire." An amateur of my acquaintance grew Grapes of superior quality without any fire heat, such Grapes that held their own at autumn exhibitions. Thinking to achieve still greater results he at considerable cost heated his vinery, and never afterwards produced Grapes of such fine quality as before when the sun did all the heating.

I believe that Grapes may be satisfactorily grown without a shovelful of coals in any sheltered situation south of the 53° of latitude, except, perhaps, in the dull western counties; on the more sunny east coast as far as Yorkshire I know they may be so grown in sheltered gardens. It would be instructive if gardeners residing further north than the locality indicated would state their experience on this question. I have seen very fine Grapes grown in Nottinghamshire without any fire heat having

been applied. Will they not succeed also in Derbyshire, Leicestershire, and Staffordshire under the same conditions? and what about Shropshire, Herefordshire, Warwickshire, and other of the inland counties?

If evidence can be afforded that Grapes can be produced in the counties alluded to under the simple conditions suggested a great impetus will be given to the erection of plain vineries as adjuncts of the homes of many who otherwise cannot obtain Grapes either for their own families or for distributing amongst their sick neighbours. Vineries and icehouses in country districts are far more beneficial than alehouses, and every encouragement should be given for the erection at least of the inexpensive and enjoyable structure first mentioned.
—A LINCOLNSHIRE GARDENER.

SECURING GRAFTS AND BUDS.

A LETTER from a correspondent detailing the loss of some much-cherished grafts by their not having been properly secured reminds us that many grafts and buds are annually broken off by the wind. Remedies are often submitted just too late to be of use, and warnings circulated after evil has been

Fig. 6.

done. Grafts are now growing rapidly, and buds of Roses and of fruit trees are many of them in danger of being blown out by the storms and gales. In many cases the stocks themselves may form the means of support; all that in such a case is required is the securing of the graft to the stock as represented in the engraving from the excellent work of M. Baltet, the stock being shortened at the winter's pruning at the point D. In other cases stakes affixed in the ground and reaching a sufficient height to afford the requisite support are necessary, or in the case of standard trees and Roses stakes must be affixed to the stems of the trees in such a manner that the new and as yet insecure growths can be fastened to them. Whatever means are adopted for securing the grafts let them be adopted in good time, or injury may be done in an hour that cannot be repaired in a year. Be the grafts or buds few or many, it is important that they be made safe at this period of the year—hence this reminder, suggested by a loss that has caused much regret.

ROSES.

COULD not prizes be offered for Roses which were cut a certain number of hours before the time fixed for judging? This would place those competitors coming from a distance on an equal footing with those who live on the spot. Of course

the judges would have to trust in the honour of competitors, but I hope that there are not many true Rose lovers who are not men of honour.

I have noticed that soft soap has a very bad effect on light-coloured Roses; for instance, John Hopper and similar sorts, turning the edges of the petals a bluish purple and withering them.—C. C.

GRAPES SCALDING.

WE are approaching the time when late Grapes will be passing through the stoning process, and "scalding" is likely to occur, as it often does, owing to the false economy of dispensing with fires, which results in a low night temperature and consequent deposition of moisture during the night, which, from the powerful rays of the sun drying up the moisture, causes the destruction of the skin of the berry so acted upon. Scalding may also have its cause in too scant foliage, as in the case of Muscats, which, unless the foliage is good, not infrequently scald, or rather scorch, when they are hurried into ripening early in the season. This may be entirely prevented by hexagon netting drawn over the roof for a few hours in the hottest part of hot days. The best preventive of scalding is admitting air early and plentifully by day, and providing a night temperature of 70°, not omitting to maintain that temperature by day in a dull moist period, for in a hot time following a cold and moist one, and no fire heat being employed to supply the deficiency of natural heat, scalding is almost always prevalent.—PRACTICALIST.

THE ROCK GARDEN AT ST. ALBAN'S COURT, WINGHAM,

THE RESIDENCE OF W. O. HAMMOND, ESQ.

WHEN my friend Mr. Hammond wrote, "Will you come and see my rockery next week?" I felt glad to be able to fulfil an engagement long since made, as I was sure from all that I had heard that I should have a real treat, and hoped also to be able to let the readers of our Journal know something concerning it; for although a florist I am not by any means insensible to the charms of Alpine and herbaceous plants, and do, indeed, endeavour in my own small way to grow them. There are gradations in all these things, corresponding to the tastes and capacities of the owners, and ruled more or less by that very important factor the purse; and although after seeing such a rockery as this my own sinks into insignificance, it is some consolation to think that Mr. Backhouse has reached an eminence no amateur is likely to attain.

St. Alban's Court is situated close to the village of Nonington in Kent, about four miles from the Adisham station of the London, Chatham, and Dover Railway, in the midst of the chalk downs which give their character to the whole neighbourhood. The house, which is a very old one, is coming down, and Mr. Hammond is now building in a more elevated position a house which will be when completed a very perfect specimen of Tudor architecture, for no trouble has been spared to obtain accurate models for it throughout; and its owner's consummate taste, which is never at fault, will, I feel confident, make it what it professes to be, and no modern sham of "architects' improved Tudor."

The gardens present no special object of interest, but the Rock Garden is, next to Mr. Backhouse's, the best that I have seen. It is made in the form of an amphitheatre. The red sandstone rocks of which it is composed have been obtained from Tunbridge Wells and Hawkhurst, and are well adapted for the purpose. They are very naturally arranged, and placed so as to afford suitable houses for the various tribes of plants cultivated. On the more elevated portions Saxifragas, Sedums, &c., grow in profusion; others are placed on the face of the rocks, while there are boggy places in which Cypripediums, Pinguiculas, &c., find their home. In all the earlier months of the year such a garden affords a continual source of interest and pleasure, and for months a succession is kept up. When I went the Primulas, Gentians, &c., were over, but they were succeeded by many equally interesting. Take for example the well-known Edelweiss (*Leontopodium alpinum*), dear to all who have travelled in Switzerland as a memento beautiful in itself of many enjoyable days. This, the result of Mr. Hammond's own wanderings, is to be found growing quite at home in various places in the rockery. And here let me say that the owner's interest in this garden is not that merely of one who likes these plants, but of one who makes frequent expe-

ditions in search of them, and many of them have a personal history. Here, for example, are splendid groups of the lovely *Ramondia pyrenaica* in far greater abundance and beauty than I have ever seen it before. "This," says Mr. Hammond, "first made me a lover of Alpines. I was travelling in the Pyrenees and saw it growing above me on the face of a rock. I marked the spot, and on my return mounted on my friend's shoulders and secured it." It is grown here in the shade of the rocks with comparatively little soil, and seeds abundantly. Amongst the Saxifragas were to be found *S. longifolia*, undoubtedly the queen of Saxifragas; but no plant here was equal to one which Mr. Hammond had some time ago, which measured 14 inches across. I have a very fine one myself, now, alas! in flower, the stem quite 2½ feet high, but killing itself, I fear, with the effect. *S. Burseriana*, with its silvery compact tufts; *S. calyciflora*, with stiff, cylindrical, silver-edged rosettes; *S. oppositiflora*, of course now past, but evidently thriving, and earlier must be a thing of beauty. Some of the mossy section were also very luxuriant, forming dense cushions of velvety green and covering the surface of the rocks. In a deep boggy piece to which a supply of water can be let on were found a quantity of the Butterwort (*Pinguicula*), which had been brought from Scotland. *Cypripedium spectabile*, the beautiful North American species, was doing well, as was also our pretty English one *C. calceolus*. The Androsaces, as all lovers of Alpines know, are difficult to manage, but one of them at least—*A. lanuginosa* with its woolly foliage—is grown well here, having been raised from seed, as also does *Saponaria cespitosa*. *Geranium cinereum* is one of the prettiest of an extensive genus, bearing large and handsome pink flowers veined with red on plants 2 to 6 inches high. *Geranium argenteum* is another low-growing, almost prostrate species. Of the *Drabas* *glacialis*, *cuspidata*, and *gigas* were in full vigour, as were also the *Soldanellas* and *Globularias*. Then the lovely little *Lychnis alpina*, delicate enough for a fairy's bouquet, was in flower. There were also large masses of the beautiful *Silene acaulis*, which forms so lovely a contrast to the brilliant blue of *Gentiana verna*, but these had past. The latter had been successfully grown by placing it amongst some minute-growing Alpine, as it has done with me amongst *Arenaria balearica*.

However, it is needless to run through the names of the Alpines to be found here. Suffice it to say that whatever is really good is sure to find its way to this garden, and whoever really loves flowers for their own sake ought to try and extend such a taste as this. If a man be strong and young, then the records of many an expedition will bring to his mind as he goes through his garden many pleasant memories and afford unceasing pleasure, as I know they do to the owner of St. Alban's Court.—D., Deal.

MY CHRYSANTHEMUM HOUSE IN SUMMER.

THE winter bloom of Chrysanthemums past I prepare the borders by trenching and working into them a quantity of good rotten dung for a summer display of Fuchsias which I have ready for planting. They are struck in a cold frame in June the previous year, and are nice little plants about a foot in height. I plant three rows in each border, keeping free growers in the back rows, mixing the colours, and planting them alternately about 16 inches from plant to plant. When planted and the borders well watered I pot off all bedding Geraniums and any other small plants requiring potting and place them on the surface of the border, taking care not to smother the Fuchsias. Of course the Fuchsias would be as well without them; but space under glass is valuable, and the treatment required for young Fuchsias just suits the newly potted plants, such as keeping the house pretty close and sprinkling often. In April I remove all the bedding plants to cold frames. The Fuchsias by this time are growing pretty freely, so I hoe and clean the border, pinch and stake any that are inclined to run away from their friends, fumigate if required, and give the borders a good watering. In regard to water, the Fuchsia, like the Chrysanthemum, must get plenty, and occasionally manure water, besides sprinkling overhead. The planting-out system reduces this labour one-half, besides saving pots and the time taken up by the different pottings, prolongs the time of flowering, gives finer blooms, and is altogether the most natural. Last season the Chrysanthemums were bloomed in another house as I wanted to renew the borders of this one, and instead of being thrown out in the autumn were left for a time, and at Christmas there was still a good show of Fuchsias. I keep the flowers picked off till

the plants get established in the borders, and during the summer remove all seed pods. About the middle of June I prepare a cold frame with about 6 inches of light soil, such as equal parts of loam, leaf mould, and sand, pressed pretty firmly; select as many cuttings as are required, dibble them in, give a good watering, shade from bright sunshine, and keep the sash close till rooted, when they get air gradually, and the sash is removed altogether as soon as the young plants can bear full exposure. There they remain till autumn, and all they require is a good watering with a rose if the weather be dry. Free growers are pinched and all blooms picked off. Before winter sets in I pot them off, using a light rich soil, and from 3 to 5-inch pots, according to size of plant. Most of them keep growing all winter, so they must not suffer for want of water, and must be kept clear from green fly. I store them in a cool greenhouse along with bedding plants.—ALEX. M'MILLAN (in *The Gardener*).

ROSE MÉLANIE WILLERMOZ.

NEVER before have I seen this Rose so beautiful as it has been this summer; and it is not improbable that I might have remained ignorant of its full value if I had seen it, as in other years, under its ordinary guise of a bush trained to a wall. The plant was vigorous and healthy enough, but with its flowers so pendant that the interiors are not visible unless turned up to sight with the hand. This year, however, it has been my good fortune to see an unusually large plant of it that had thrown its stout rampant shoots over the top of a wall buttress and in that position put forth flowers abundantly—nothing could be more charming. At a little distance off one was attracted by the mass of large snowy blossom—some nestling among the large, deep green, handsome foliage, and others resting upon it and upon each other, drawing one on involuntarily to a closer inspection, which was well rewarded by a full view of the interior of so many fine blooms tinged in the most exquisite manner with a soft yet bright pink tint, each petal receiving and imparting beauty to the others.

This fine Tea-scented Rose should be associated with *Maréchal Niel*, the pendant flowers of both requiring a high wall or building to show their full beauty, both being as well worthy of an extra amount of space as they are adapted for it naturally by their free strong growth.—EDWARD LUCKHURST.

THE LATE SHOW AT PRESTON.

SUPPLEMENTARY REPORT.

OWING to the celerity with which our report of the Royal Horticultural Society's Show was transmitted by electric telegraph one or two slight errors crept in; they were so few, however, and generally unimportant that we readily bestow a word of praise on the telegraphic operators engaged at Preston.

A few corrections necessary to be made are the following:—Messrs. Rollisson & Sons, not Mr. Robinson, had the first prize for six Orchids; Mr. Mackellar, gardener to Sir James Watts, Bart., Abney Hall, and Mr. Cowan had the second and third prizes respectively in the class for baskets of Grapes. Mr. Harris, gardener to Mrs. Vivian, Singleton Abbey, had the first prize for the best Queen Pine Apple, which was credited to Mr. Gretton; and for three Pine Apples Mr. Hepper, gardener to C. O. Ledward, Esq., not Mr. Coldward, had the first prize. J. Dodds, Esq., Penwortham, had the chief, indeed the only, prize awarded for Fuchsias; Mr. Barron, Elvaston, had the first prize for a hundred hardy plants—not hardy, and stove, and greenhouse plants, as stated in the report; and Mr. Harding, not Mr. Hardy, had the third prize for *Dracænas*. An official list, however, of the prizes awarded appears in our advertising columns, and to this we refer our readers.

A few of the prominent honours granted after we left the Show may be referred to, also some of the more notable plants and collections, with a fuller reference to the other sections of the Show than it was possible to give last week. To the marvellous collection of specimen plants exhibited by Mr. Shuttleworth a gold Lindley medal was worthily awarded. The collections comprised about forty ornamental-foliaged plants and Ferns, and eighteen flowering specimens. Amongst the latter the good old *Plumbago capensis* was admirably grown; it was a delicate blue floral mass about 5 feet by 3. *Lapageria alba* was remarkably fine, and *Statice* were quite splendid. *Dipladenia Brearleyana* was remarkable by its large richly coloured flowers, and *Allamanda Hendersonii*, *Ixora Colei*, Orchids, and Heaths were all exhibited in excellent style. The flowerless section included *Gleichenias*, grand in size and symmetry, brightened by splendid *Crotons* and a fine specimen of *Yucca filamentosa variegata*, which is quite one of the most effective of variegated plants. *Davallia Mooreana* was very

fine, and still finer was *Nephrolepis davallioides*. One of the finest specimens extant of the true *Cordyline indivisa* attracted much notice, and Palms and Cycads were admirably represented. The collection as a whole was such as we have never before seen arranged by any exhibitor.

A gold Lindley medal was also awarded to Messrs. James Veitch & Sons for their remarkable miscellaneous group of plants—remarkable alike by its richness, variety, and admirable arrangement. Than the noble *Alocasias*—*Veitchii*, with its handsome corrugated leaves nearly 3 feet long, *Thibautiana* and *Warroqueana* with their massive foliage and ivory-like veins—no plants in the Show were more striking. Gorgeous Orchids, curious Pitcher and insectivorous plants, brilliant-coloured *Crotons*, elegant Ferns, fine *Gloxinias* and *Begonias*, &c., were represented in this singularly beautiful and diversified collection. Mr. B. S. Williams was awarded a large gold medal for a smaller but very beautiful group composed of plants of great value. Orchids, *Dracænas*, *Nepenthes*, *Crotons*, &c., were of such quality and arranged in such a manner as to well merit the award granted. The same remark applies to the adjoining collection of Messrs. Rollisson and Sons, for which a gold medal was also awarded. Besides the *Ericas* in this group which were referred to last week, remarkably fine *Dracænas*, Orchids, and *Crotons* commanded much notice. The collections of plants referred to, taken in the aggregate, and arranged as they were near the entrance of the tent, constituted one of the most imposing and most admired features of the Exhibition. Silver medals—a Flora to Messrs. Cranston & Co., and Banksians to Mr. Prince and Mr. Davison—were granted for Roses.

First-class certificates were awarded to Mr. J. R. Pearson, Chilwell, for a beautiful trio of Cape Pelargoniums—Beauty, rosy pink, maroon blotch, white centre; Pixie, dark rose, chocolate blotch, pale centre; and Ariel, rosy crimson maroon blotch and feather, and pale centre. The blotches are on all the five petals of the above varieties, and the plants are dwarf in habit and floriferous. A first-class certificate was, we were informed, granted to Mr. D. Thomson, Drumlanrig, for a fine seedling *Croton*, but we had not an opportunity of seeing the plant. Messrs. Downie and Laird, Edinburgh, exhibited cut blooms of Pansies remarkable for their bright and varied colours and clearly defined lacing, and were commended by the Judges.

We next refer to some of the more noteworthy plants in the competitive collections. The finest specimens were undoubtedly those staged by Mr. Tudgey, gardener to J. F. G. Williams, Esq., and Mrs. E. Cole & Son in the class for sixteen plants, eight of them in bloom. Mr. Tudgey, who won first honours, may now be regarded as the champion specimen plant exhibitor. His example of *Erica Parmentieri rosea*, a perfect globe 5 feet in diameter, is a model of good culture, and *E. tricolor impressa* bore the impress of a master hand. *Ixoras coccinea superba* and *Dixiana*, *Clerodendron Balfourianum*, *Dipladenia amabilis*, and *Allamanda grandiflora* were all well grown and admirably bloomed specimens. The fine-foliaged plants, which consisted chiefly of Palms, Cycads, and *Crotons*, were very large, but some of them were somewhat worn by having been previously exhibited. Messrs. Cole's collection was one of great excellence. The fine-foliaged plants were in splendid condition, surpassing those staged by their rival, but some of the flowering plants were rather weak. The best specimen, and fine it was, was *Ixora Colei*. *Dipladenia amabilis* was very good, as also were one or two *Ericas*. Two *Azaleas*, Brilliant and President, were wonderfully fresh for the time of year but were small. *Crotons angustifolium*, *Weismannii*, and *Johannis* were in brilliant colour, and the Palms and Cycads were in exuberant health. Mr. Tudgey may be justly proud of beating such a meritorious collection. In the class for twelve plants in bloom Mr. Tudgey was the only exhibitor, and staged specimens of the same good quality as those above described. In the class for six plants in bloom, also in that for twelve plants six of them in bloom, Mr. Pilgrim won the chief honours with excellently grown specimens, especially of *Cycas circinalis*, *Latania borbonica*, *Croton longifolium* (fine), *Phormium tenax variegatum*, *Anthurium Schertzerianum*, *Bougainvillea glabra*, *Clerodendron Balfourianum*, and *Stephanotis floribunda*. Heaths were only of moderate size, and the plants were more or less drawn, probably by having been retarded in shaded places. Some good stove and greenhouse plants were staged by local exhibitors in response to several prizes offered by the Preston Nursery Company, but owing to the old and bad system of judging under number and the waste of time it involves in affixing the prizes we could not wait for the awards.

Orchids were not numerous, the season being late for these gorgeous flowers, yet some fine collections were staged. In the amateurs' class Mr. Osman, gardener to R. B. Dodgson, Esq., Blackburn, who won the chief prize in the class for twelve plants, exhibited admirable examples of *Cattleya Warnerii* with thirteen flowers, and C. Mendeli with eleven, *Vanda suavis* seven spikes, *Aerides odoratum* nine spikes, *Dendrobium densiflorum* and nobile, and some very fine *Cypripediums*. Smaller but very good plants were staged by Mr. Mitchell, gardener to Dr. Ainsworth; *Aerides Lobbi* *Ainsworthianum* was very beautiful in this group. Amongst Mr. B. S. Williams's twelve first-prize plants, which were not noticed last week, we observed excellent examples of *Dendro-*

biums formosum giganteum, densiflorum, and Bensoniæ; Cattleyas Mendelii (fine), and Leopoldii; Cypripediums barbatum superbum and niveum; Aërides odoratum majus; Epidendrum vitellinum majus, and Lælia purpurata.

Fine-foliaged plants were excellently represented in the several classes. Noteworthy were remarkably healthy Palms and Cycads from Mr. Pilgrim, well grown and admirably coloured Crotons and fine Ferns from Mr. Rigg, gardener to James Foreshaw, Esq., Fulwood, Preston; capital Crotons, Palms, and Alocasias from Mr. Osman; and remarkably well-grown plants from Mr. Hammond, gardener to Sir Wilfrid Lawson, which were noticed last week. Crotons were both numerous and excellent, nearly all the plants being well grown and in fine colour. *C. angustifolium*, *C. Weismannii*, *C. undulatum*, *C. picturatum*, *C. Johannis*, *C. Rex*, and *C. Disraeli* were amongst the more striking of the specimens; and of the smaller and newer varieties *C. Hanburyanum* and *C. maculatum* Katonii exhibited by Messrs. Veitch; *C. Prince of Wales*, *C. Williamsii*, and *C. Victoria*, exhibited by Mr. B. S. Williams; and *C. Mortii* and *C. roseo-pictum* in Mr. Bull's collection, were much admired. *Dracenas* were stately and rich, and were seen to great advantage on the isolated circular mounds near the water. Messrs. Rollisson's first-prize collection included *Salmonæ*, *amabilis*, *Baptistii*, *Smithiana*, *Nitzschnerii*, *Gladstonei*, *Guilfoylei*, *Youngii*, *Regina*, and *Goldiana*.

Ferns were good, but not grand. Mr. Pilgrim exhibited fine *Gleichenias*, as also did Messrs. Cole and Mr. Dodgson. The Preston Nursery Company staged fresh and healthy Tree Ferns, and Mr. Osman excellent *Adiantums*. Hardy Ferns were well exhibited by Mr. Bolton, Fern Cottage, Warton; Mr. Pilgrim, and Mr. E. J. Lowe. The collections were chiefly composed of varieties of *Athyriums*, *Polystichums*, and *Scelopendriums*.

In the classes for new plants the results both as to plants and prizewinners were repetitions of the classes at previous great shows—Messrs. Bull, Williams, and Rollisson retained their old positions with plants that have been previously enumerated. For Mr. Bull's prizes Mr. Hammond, Mr. B. S. Williams, and Mr. Tudgey again won cups; the maiden cupwinners being the Preston Nursery Company and Mr. McIntyre, gardener to the Hon. A. C. C. Maxwell, Dumfries. Mr. Bull exhibited an unnamed *Lilium* remarkable alike by its great size and rich colour. It is of the *L. auratum* type, the coloured ray down each petal being chocolate crimson. The flower had passed its best condition, yet was very striking.

Florists' flowers were only of moderate quality. Fuchsias were poor, and Pelargoniums were far from superior; but Tuberous Begonias from Messrs. J. Laing & Co., Forest Hill, were represented by the following very fine varieties:—*Gloire de Nancy*, *Lælia*, *John Laing*, *Baron Hruby*, *F. M. don Santos Viana*, a fine variety of the *Pearcei* type; and *Corail Rose*. Nine very finely grown *Gloxinias* were exhibited by Col. Cross, who was the only exhibitor in the class for those flowers.

ROSES.—"As regards quantity," writes "D. Deal," "these were but feebly represented, and had it not been for the extra collections not for competition sent in by Messrs. Cranston, Prince, Corp, and Davison they would have been still more so. Nor is this to be wondered at; the rules prohibited either nurserymen or amateurs from taking more than one prize, not in any one class, but in all the classes. It was not at all likely that the expense, time, and trouble necessary to send or go to Preston would be encountered for the chance, perhaps, of getting £1: hence not one amateur of note was there, the prizes going to some in the neighbourhood, while of our great professional exhibitors—Messrs. Cant, Paul and Son, Keynes, Turner, Mitchell, and Francis were all conspicuous by their absence.

"The collections which were sent in by the exhibitors above named were of first-rate quality—indeed I do not think they have been excelled this season. Notably was this the case with the stand of Louis Van Houtte exhibited by Mr. Cranston. I do not remember having ever seen one to equal it, and how the colour of such flowers is preserved passes my comprehension. I was again in the tent on Thursday afternoon, and yet the freshness and vividness of colour had not departed from those glorious flowers, while in all the stands there was far more staging quality than I thought they could have possessed. In his seventy-twins were grand examples of *Duchesse de Morny*, which has quite taken a first rank this year; *Camille Bernardin*, *Antoine Ducher*, *Etienne Levet*, *Comtesse d'Oxford*, *Mdlle. Marie Rady*, *Xavier Olibo*, very grand; *Duke of Edinburgh*, *Marie Baumann*, *Le Rhone*, *Le Havre*, *Alfred Colomb*, and *Madame Lacharme*. In the class for forty-eights Mr. Prince's collection was a grand one, and taking it altogether was about the most even lot that I have seen exhibited this year; there was not even an indifferent bloom in it, while many of them were superb. I have never seen *Richard Wallace* so well shown as in this stand; there were besides magnificent blooms of *Dupuy Jamain*, *Mdlle. Marie Rady*, so good that it was difficult to distinguish it from a good bloom of *Marie Baumann*; *Baronne de Rothschild*, *Le Havre*, very fine; *Reynolds Hole*, very good; *Mons. E. Y. Teas*, *Auguste Rigotard*, *Madame Charles Wood*, *Comtesse de Nadaillac*, most lovely; *Jean Ducher*, *Souvenir d'Elise Vardon*, which has everywhere been shown grandly this

season; *Niphetos*, &c. Mr. Corp's collection also contained some excellent blooms, amongst them *Star of Waltham*, *Marie Cointet*, *Edouard Morren*, *Mons. E. Y. Teas*, and *Marguerite Brassac*. In the exhibits not for competition there were some grand blooms of well-known varieties, but nothing that calls for special notice."

FRUIT AND VEGETABLES.

FRUIT.—To gardeners, and indeed to many of the visitors, the vegetable and fruit tent possessed the greatest attraction. A prominent, and one might say rather unusual, feature in this tent was the generally good quality of the exhibits. The collections of fruit, though limited in number, were certainly very good, and fully deserved the awards made to them. The class for Black Hamburg Grapes was a particularly good one, fourteen lots being staged, and the prize bunches were in every respect excellent. The Muscats throughout were very fine in bunch and berry; none, however, were really ripe or "finished." The *Madresfield Court* and *Foster's Seedling* were also well shown. There was nothing sensational among the Pines. Only Queens were staged. All were very good, the prizewinners particularly so. The Peach class was a capital one. All three prizes were won with the *Bellegarde*. This variety is undoubtedly one of the best in cultivation, and ought to be in every collection however limited. The same remark applies to *Elruge Nectarines*, of which there were many fine highly coloured dishes both in the collections and in the class for single dishes. There were many larger fruit staged than either *Bellegarde Peach* or *Elruge Nectarine*, which, however, did not find favour with the Judges. Melons were shown in good numbers. A fruit of *Golden Queen* gained the premier award. This good old variety is of easy culture, but seldom of late years has been found placed first in competition with newer varieties. Another excellent old variety—*Conqueror of Europe*—was placed second. The *Khiva Melon* is evidently inconstant, as fruits were staged of various shapes. The Strawberries were very good, but on the whole were not equal to those we have seen at some local shows this season. The dishes of *Oxonian* (by some grown under the name of *Eleanor*) were the most attractive. *British Queen* and *Dr. Hogg* were also well shown. The first-prize collection of ten dishes consisted of the following:—*Marguerite*, *Sir C. Napier*, *Oscar*, *President*, *Eleanor*, *Cockscomb*, *Wonderful*, a *Seedling*, *Dr. Hogg*, and *Sir Harry*.

VEGETABLES.—Some of the collections of vegetables, notably those which gained two first prizes for Mr. Miles, were beautifully staged, and the vegetables were of the finest quality. Mr. Miles's Carrots, Peas, and Tomatoes were excellent. The schedule offered no inducement for superior staging, but it is very probable that a liberal use of Parsley influenced the Judges in their decision with regard to the second-prize collection staged for the Society's prizes, as this collection we thought inferior to others in the same class which received no award. Cucumbers generally were not superior. Exhibitors, as in this instance, too frequently err in staging too large overgrown specimens. Tomatoes were shown well, a round good-shaped variety of the *Excelsior* type receiving the preference from the Judges. The Peas generally were very fine, those shown in competition for Messrs. Carter's prizes—viz., *Culverwell's Telegraph*, *Carter's Little Wonder*, and *Challenger*, being remarkably so. These varieties were largely shown in the other classes; also *Laxton's Supplanter*, *Criterion*, *Ne Plus Ultra*, *Dr. McLean*, *Suttons' Giant Emerald Marrow*, and *Duke of Edinburgh*. The competition for three varieties of Potatoes was very spirited. The first-prize collection consisted of *Snowflake*, *Porter's Excelsior*, and the *Waterloo Kidney*. A dish of the *Prince of Wales Kidney* was very good. White *Tripoli Onions* were very fine indeed, and there was some very good unnamed white Celery exhibited. Cauliflowers throughout the Show were much too large. Some excellent Turnips were shown, the best being *Suttons' Snowball*. Messrs. Sutton & Son's prizes for collections of vegetables did not attract much competition, but this is accounted for from the fact of their conditions necessitating the competitors growing their vegetables in the open air, and certain stipulated varieties were too late this season. The idea is a good one, as it gives gardeners with a limited quantity of glass a better chance against their more favoured rivals.

IMPLEMENTS.—The principal collections were referred to last week. Messrs. R. Halliday & Co. were awarded the gold medal for a collection of glass structures, and a silver medal for garden appliances, which included boilers and improved valves for hot-water pipes. Messrs. W. Rollisson & Co. were awarded a silver medal for a combined water and plant barrow, a very useful aid to nurserymen and gardeners. Besides the collections previously noticed we observed the patent paragon greenhouse and other structures glazed without putty, exhibited by Messrs. Horley of Toddington, Beds. Mr. J. H. Critchley of Cheltenham exhibited specimens of patent hot-water regulators, and a brass model of the large boilers in the Palm stove at Kew, shown by Messrs. Simpson & Co. of London. Mr. Matthews of Weston-super-Mare exhibited an extensive display of garden pottery. Fumigators, waterproof labels, paper flower pots, &c., were shown by Messrs. Blake & Mackenzie of Liverpool. Water engines and hose reels

from James Quin & Co. Samples of peat came from Mr. W. J. Epps of Vauxhall, and Messrs. James Fraser & Co. of Leighton Buzzard.

Although as an exhibition the Show was a success the administration of it, especially as regarded the system of judging and placing of the awards, was very faulty. It is probable that the Royal Horticultural Society will at future shows retain more of the management in the hands of their own officials, as local administrators, however zealous they may be, cannot be expected to carry out the details of a Show of such magnitude smoothly and well.

The fixture of the Show proved somewhat unfortunate. The weather on the opening day was unpropitious, and on the second day the opening of the Winter Gardens at Blackpool by the Lord Mayor of London attracted many thousands of local visitors; yet we are glad to learn by a special telegram from Preston that the Show is regarded there as a success and is expected to clear itself financially. The admissions on Wednesday (a dull showery day) were 460; on Thursday (the Blackpool demonstration), 1123; on Friday, 5140; on Saturday, 12,320; on Sunday, 520; and on Monday (an extra day), 5032. Total, 24,595.

To Mr. Troughton and all the officials of the Show we are indebted for much courtesy; and the Exhibition was rendered enjoyable by the excellent order kept by a detachment of the metropolitan police. We hope at the next provincial to find metropolitan—i.e., South Kensington and Chiswick officials, discharging their usual duties in their wonted smooth and efficient manner.

OUR BORDER FLOWERS—COMPOSITES.

WE may say of this family that they would require a field of no very small dimensions to cultivate them, but there are many of the family that are useful for decorating our borders and other places in the spring and summer time. Some of them we find to be indispensable for flower garden purposes, and in other ways we find them useful, not the least being for cutting from for indoor decoration, and some of the species have done us good service on the exhibition table. The species vary much in stature; some are small and compact, others are almost of unruly dimensions.

White and yellow are the predominating colours of the Achilleas, the name of which is said to be derived from Achilles, a disciple or pupil of Chiron, who first used the plant for the healing of wounds. The Sneezewort (*Achillea Ptarmica*), when dried and converted into fine powder and taken as snuff produces sneezing. *Achillea Ptarmica plena* is a very useful border flower in dry situations. It is said of our common Milfoil (*Achillea Millefolium*) that water and proof spirits extract the virtue of this plant, and by distillation it yields a penetrating essential oil, possessing the peculiar flavour of the plant in perfection. It is also said that it possesses narcotic properties, imparting to beer an additional intoxicating quality. I have known inveterate smokers use it as tobacco. *Achillea compacta* is a very striking plant with its great yellow plate-like flower heads. In open spaces in the shrubbery or other places when once well established it lasts a long time. It is not at all particular as to soil, and requires staking to keep it from being broken by the wind, as it attains the height of from 4 to 5 feet. The dwarfier kinds, as the Golden Milfoil (*Achillea aurea*), is a fine late summer and autumn border and edging plant, deserving of extensive cultivation. The Silver-leaved Milfoil (*Achillea Clavennæ*), is one of the most effective of bedding or edging plants we possess. It is useful also for pot culture for indoor decoration.

There are others of this numerous family that are equally useful for edging purposes. The red variety of our common Milfoil (*Achillea rosea*), is a showy border flower, and lasts a long time in flower. The variegated form of *Achillea Millefolium* would be seen more frequently if its merits were sufficiently known.

A word for our Downy Milfoil (*Achillea tomentosa*), and then I must leave the family. It is a fine plant of very dwarf habit for rockeries, borders, or pots; but is most at home on the limestone. Some of them are increased by seed, and all may be increased by division in the spring when growth is commencing.—*VERITAS*.

IMPRESSIONS OF THE NATIONAL ROSE SHOW.

IN your number of the 4th inst. "A. C." gives us his impression of the National Rose Show, and he makes particular mention of Jean Liabaud, for, although admitting its wonderful colour, he states that it is "inferior in form to the good old Camille de Rohan."

I have had a fortnight's acquaintance with Jean Liabaud.

Since it gladdened me with its first bloom my first visit every morning has been paid to it, and my last one in the evening. I find my steps involuntarily tending in its direction in order that I may get another and yet another view of the grandest velvety Rose which, in my humble opinion, has ever been raised; and as to invidiously comparing it with Camille de Rohan, all I can say is that I heartily wish "A. C." had seen the glorious blooms of Jean Liabaud which I have regarded so lovingly. Its wondrous colour and perfect form, its fullness and free-blooming, will place Jean Liabaud, I firmly believe, in the front rank of the velvety class. My plant is on the Manetti.—C. W. MILNE, *The Rosery, Selby Park*.

WEST KENT HORTICULTURAL SOCIETY.

JULY 13TH.

THE annual Exhibition of this Society was held at Widmore, Bickley, on Saturday last. The site chosen for the tents was an admirable one, the weather was splendid; the temperature under canvas was perhaps a little too warm, but the grateful shade under some fine old trees where the numerous visitors congregated to enjoy the music afforded full compensation. The Exhibition was displayed in four tents. The first, a very large one, contained several elaborate collections of plants from our leading nurserymen; the second was filled with productions of both the gardeners and cottagers (principally plants); the third marquee was set apart for dinner-table decorations, bouquets, button-holes, &c.; and the last tent, but by no means the least, was well filled with Roses, fruit, and vegetables.

In the large tent Messrs. Veitch & Sons occupied the centre stage at one end, and Messrs. Laing & Co. the other end. About midway on either side were extensive collections from Messrs. Carter & Co. and Mr. Wills, Anerley Nursery. Messrs. Rollisson and Sons staged a very effective group in another tent, and the collections from Mr. Ley of Croydon, and Messrs. F. & A. Smith, Dulwich, were very prominent. The whole of these collections commanded much attention, for in them were to be found the cream of the new and rare plants with which our nurseries abound—plants which we hope by-and-by to see in larger-grown specimens at future exhibitions.

Roses constituted one of the principal features of the Show. Near the entrance were a dozen boxes not for competition from the Putney Vale nurseries of Messrs. Veitch & Sons; amongst them we noticed fine examples of *Souvenir de Monsieur Boll*, *General Von Moltke*, *Pauline Talabot*, *Jean Souper*, *Mlle. Eugénie Verdier*, *Duchesse de Vallombrosa*, and *Rev. Reynolds Hole*. In competition for forty-eight varieties three trusses of each, for which prizes to the value of £5, £3, and £2 were offered, also for twenty-four varieties, distinct, and twelve Roses of any one variety, those veteran growers Messrs. Paul & Son of Cheshunt and Mr. Cant from Colchester were placed first and second respectively in each class for exquisite collections. Messrs. Paul and Son's forty-eight trebles comprised *La Duchesse de Morny*, *Mons. Boncenne*, *Baronne de Rothschild*, *Senateur Vaisse*, *Centifolia Rosea*, *Maurice Bernardin*, *La France*, *Mlle. Prosper Langier*, *Charles Lefebvre*, *Queen Victoria*, *Pierre Notting*, *Mlle. Marie Rady*, *Olivier Delhomme*, *Mlle. Eugénie Verdier*, *Louis Van Houtte*, *Abel Grand*, *Henri Ledechaux*, *Monsieur E. Y. Teas*, *Mlle. Thérèse Levet*, *Camille Bernardin*, *Marie Louise Pernet*, *Elie Morel*, *Devienne Lamy*, *François Michelon*, *Duke of Edinburgh*, *Marguerite de St. Amand*, *Exposition de Brie*, *Annie Laxton*, *Duc de Rohan*, *Princess Beatrice*, *Edouard Morren*, *Jean Liabud*, *Mme. Hippolyte Jamain*, *Marie Baumann*, *Felix Genero*, *Marguerite Brassac*, *Niphotos*, *John Stuart Mill*, *Marie Finger*, *Abel Carrière*, *John Hopper*, *Alfred Colomb*, *Star of Waltham*, *Xavier Olibo*, *Comtesse de Serenye*, *Horace Vernet*, and *Reynolds Hole*. Mr. Cant's collection contained splendid blooms of *Madame Charles Wood*, *Etienne Levet*, *François Louvat*, *Dupuy Jamin*, *Louise Peyronny*, *Madame Sophie Tropot*, and *Ville de Lyon*. Mr. Coppin, Croydon, was awarded the third prize in this class; and in the class for twenty-four varieties it fell to Mr. Laing, Forest Hill, both showing very good collections. A splendid box of *Baronne de Rothschild* from Mr. Cant was awarded the first prize for twelve Roses of one variety, Mr. Coppin taking the second place with *Marie Louise Pernet*, and Mr. Laing third with *Marie Baumann*. Several other boxes of Roses not for competition were staged by Messrs. Laing and Coppin, and were very much admired, especially those dark Roses *Louis Van Houtte* and *Reynolds Hole*, of which these stands contained grand examples.

In the classes set apart for amateurs Captain Christy, Westerham, Kent, was an easy first with a very even box of twenty-four blooms, distinct, composed of *Madame Clémence Joigneaux*, *Baronne de Rothschild*, *Mlle. Marie Rady*, *Capitaine Christy*, *Mlle. Eugénie Verdier*, *Edouard Morren*, *La France*, *Dr. Andry*, *Louis Van Houtte*, *Marquise de Castellane*, *Alfred Colomb*, *Duke of Edinburgh*, *Abel Grand*, *Comtesse de Serenye*, *Dupuy Jamin*, *Madame Hippolyte Jamain*, *Prince Camille de Rohan*, *Felix Genero*, *Camille Bernardin*, *Marguerite de St. Amand*, *Marie Baumann*,

Madame Charles Crapelet, Madame Thérèse Levett, and François Michelon. Mr. Moore, gardener to W. C. Pickersgill, Esq., was awarded the second prize, and Mr. Maynard, gardener to J. Whitehead, Esq., third. For twelve Roses, distinct, Messrs. Talmage, Field, and Cole were placed in the order of their names; and for six of any one variety Captain Christy won the first prize with Marie Baumann.

PLANTS.—Substantial prizes were offered both for stove and greenhouse plants, fine-foliage plants, and for show and fancy Geraniums; but the Show is held too late in the season for many large flowering plants, particularly Pelargoniums. The nine fine-foliage plants from Mr. F. Moore were excellent; *Livingstonia altissima*, *Croton Weismannii*, *Alocasia metallica*, *Cycas revoluta*, *Marantas Veitchii* and *Makoyana*, *Cocos Weddelliana*, *Areca lutescens*, and *Alocasia macrorrhiza variegata* were in admirable condition. Mr. Gammon was placed second and Mr. Mumford third. Mr. Mumford staged an exquisite group of flowering and fine-foliage plants, amongst which were two very large specimens of *Allamanda Hendersonii*, *Anthuriums*, *Begonias*, *Orchids*, *Dracenas*, &c. Mr. Coppin took the principal prizes in all the classes for Geraniums. Both flowering and foliage *Begonias* were well staged; Messrs. Talmage, Sawyer, and Gammon were the principal prizetakers. *Lycopodiums* came from Mr. Pepper, gardener to G. W. Norman, Esq.; they were very good indeed, and well deserved the first prize awarded to them. For a single specimen *Lycopodium* Mr. Talmage won the first place with a large plant of *L. Martensii variegatum*. *Caladiums* and *Gloxinias* were extensively shown and well finished. Messrs. Bridger, Maynard, and Mumford secured the prizes for *Gloxinias*; and Mr. Mumford, Mr. Bridges, and Mr. Archer in the order of their names for *Caladiums*. Hardy Ferns were particularly fine, and Mr. Moore's huge single specimen Fern of *Davallia Mooreana* commanded general approbation. This plant is quite 8 feet in diameter and in the perfection of health.

FRUIT.—This was not extensively exhibited, but was of a fair average quality. For a collection of six dishes Mr. W. Pepper took first honours, and Mr. J. Horwood, gardener to J. L. Lovibond, Esq., the second. The best three bunches of black Grapes came from Mr. J. Maynard, gardener to J. Whitehead, Esq., and the best Muscats from Mr. Pepper. Peaches and Nectarines were fairly exhibited, and Strawberries numerous considering the lateness of the season. Mr. John Archer was placed first for a Melon, Cox's Golden Gem, and Messrs. Clifford and Pepper were second and third respectively.

VEGETABLES.—For a collection of nine sorts Mr. Gammon took the first prize, C. L. Norman, Esq., the second, and Mr. Maynard the third, all exhibiting excellent produce. For six dishes Messrs. Archer, Eke, and Cole were placed in the order of their names; they also held similar positions in the class for a collection of salads. Cucumbers were plentiful and good, the prizes falling to Messrs. Pepper, Eke, and Gearing. A splendid collection of vegetables and a dozen sorts of Potatoes not for competition staged by Mr. J. Neighbour, gardener to G. Wythes, Esq., deserve notice: had they been placed in competition it is certain they would have wrested first honours from the other competitors. We also noticed several good collections of flowering and foliage plants from the same exhibitor, but not in competition. Mr. Cannell of Swanley exhibited several boxes of cut flowers of *Verbenas* and double and single *Geraniums*.

Dinner-table decorations were on the whole very tastefully arranged. Button-holes were good, but the hand bouquets were generally poor. Mrs. Wood, Bank Grove, Bromley, was awarded the first prize for dinner-table decorations, wild flowers and Grasses alone being used. This was very chaste and pretty, blue Cornflower and Grasses preponderating. Miss Beatrice Turner, Knockholt, was placed second for a table more heavily arranged. Miss Lovibond was awarded the first prize for a single decoration for the table, Miss Whitehead the second, and Miss Lucy Thompson, Swallowfield, the third prize: all showed great taste in their arrangements. For a vase or ornamental basket of cut flowers the prizes fell to Miss E. Lovibond and Miss Lovibond, who were placed first and second respectively. Miss Lovibond also won first honours for arranging the flowers for the larger dinner-table decoration, Miss Boosey and Miss Whitehead being placed second. An extra prize was deservedly awarded to Miss J. Scott, Abbyfield, for a decoration for a sideboard. The arrangement consisted of one large centre trumpet vase, two smaller end pieces, and four lesser vases at the corners. The arrangement was very light and beautiful, and the principal flowers used were white Lilies and Cornflowers, relieved with the foliage of the variegated *Acer* and fronds of *Adiantum cuneatum*.

The Exhibition was well arranged, and was attended by a very large number of visitors.

NOTES AND GLEANINGS.

WE have received the schedule of the NATIONAL CARNATION AND PICOTEE SOCIETY'S SOUTHERN SHOW, which is to be held at South Kensington on the 23rd inst. The prizes

offered are both numerous and liberal, and the classes are so arranged as to give encouragement for both large and small growers to compete. The prizes are open to all exhibitors whether subscribers or not on giving four clear days' notice to Mr. E. S. Dodwell, Hon. Secretary, 11, Chatham Terrace, Larkhall Rise, Clapham, S.W. To obtain uniformity it is urged that the collections be shown in each case in boxes, of which, for twelve, the following are the dimensions—viz., three rows of four each, from centre to centre $3\frac{1}{2}$ inches; from centre to outside, $2\frac{1}{4}$ inches; outside length, $15\frac{1}{2}$ inches; width, 12 inches; depth, $4\frac{1}{2}$ inches; to be painted a bright green. The collections of sixes should be in three rows of two each; with the flowers at the same distance from centre to centre, and centre to outside, as in the collections of twelves. The collections of twenty-fours may be composed of two boxes of twelves, making three rows of eight in each row, or in one box as may be convenient to the exhibitor, but the same space should exist between the flowers. We hope to see a large display of these beautiful and sweet hardy flowers. The Society's Northern Show will be held in the Manchester Botanical Garden on August 3rd, 5th, and 6th. Of this section the Rev. F. D. Horner, Kirkby Malzeard, Ripon, is the Hon. Secretary.

— HER MAJESTY THE QUEEN AND H.R.H. THE PRINCESS BEATRICE visited MR. CHARLES TURNER'S NURSERIES at Slough on Tuesday last, and greatly admired the Roses, Carnations and Picotees, *Verbenas*, *Fuchsias*, and the flower beds, all of which are now in full beauty.

— A PROOF copy of the entries for the NEWCASTLE SHOW which opens this day (Thursday) and continues over Friday, suggests that the Show will be a good one. The Rose entries are especially numerous, and include such famed exhibitors as Messrs. Cranston & Co., Paul & Son, Prince, Davison, Corp. Harrison, and May. The entries represent upwards of two thousand blooms, so that Roses will constitute an important feature of the Exhibition.

— WE shall be glad if any of our readers could inform us of the HISTORY OF THE LORD SUFFIELD AND STIRLING CASTLE APPLES; where and when they were raised, or any other particulars respecting them.

— MR. MOORMAN, writing from Coombe, says that the POTATO DISEASE has severely attacked some of the Potatoes grown under his care, particularly Snowflake. The disease has been very noticeable in the foliage for some days, and the tubers are also much affected. Several tubers of Myatt's Ashleaf are also found diseased; but the haulm of Snowflake has nearly decayed. He intends lifting the early crops at once, thereby hoping to save the tubers that are not affected.

— A BALTIMORE correspondent replies as follows to "ONE IN A FIX" as to PARAFFIN LAMPS:—A lamp is made in Baltimore, U.S.A., that never deposits any soot nor does it in any way blacken the bottom of the boiler. Prices from 5s. to £1. I will send a descriptive prospectus as soon as printed and order a lamp if desired. This lamp will give a degree of heat up to 500° Fah., and melt copper wire like sealing wax, and is quite safe. Cost of oil about 2d. a day.

— THE daily production of MUSHROOMS in and around Paris when the beds are in full profit is stated to be about twenty-five tons. The Mushroom caves, together with the beds in the market gardens, not only supply the Paris markets, but large quantities are exported to England and other parts of Europe, one house alone in Paris sending fourteen thousand boxes annually to London. A single French firm uses over two hundred tons of Mushrooms per annum, mostly for preserving.

— MR. W. LOVEL-CAMERON has sent us a photograph of a splendid specimen of *LILIU GIGANTEUM* which is growing in his garden near Ross, Herefordshire. The plant, which appears quite tree-like, is surmounted with, so far as we can perceive, twelve flowers. Several weeks ago we saw a similar specimen in Mr. McIntosh's garden at Duneevan. The stem of the plant then exceeded 8 inches in circumference measured at a foot from the ground. Such stately specimens of this fine Lily produce a grand effect in any garden where they can be so well grown.

— AT a recent meeting of the Royal Geographical Society Mr. W. T. Thistleton Dyer delivered a lecture on PLANT DISTRIBUTION AS A FIELD FOR GEOGRAPHICAL RESEARCH. The transference of plants from one part of the earth's surface to

the other was, observed the lecturer, brought about by the aid of the winds, migratory birds, and the currents of streams. Botanists would ultimately be able to distinguish the characteristic of plants which had existed in ages long gone by in the same manner as physiologists discovered the shape and nature of antediluvian animals. Owing to the varied and irregular conformation of the earth and to other causes, which made certain plants spread over portions of ground previously occupied by others, no broad areas of uniform vegetation were to be found on the globe, while geological disturbances had isolated at different periods groups of plants from their fellows. The plants now existing were, to an enormous extent, the descendants of plants of the most remote antiquity, and it was likely that in their case, as in that of animals, the great primal divisions of earth would be found to have been to a great extent maintained to the present day. The lecturer next alluded to the herbarium at Kew. Several valuable additions to the herbarium have been made by various travellers, among them Col. Grant, Dr. Kirk of Zanzibar, and others. Mr. New had brought from the top of Kilimanjaro some plants which on examination proved to be of the same species as those found by Commander Cameron on the other side of Africa. A tree brought from the Isle of Amsterdam by Commodore Goodenough in 1873 was discovered to be of the same species as certain trees in the small island of Tristan D'Acuna, five thousand miles away. That botanical knowledge was of value economically was shown in the discovery of an indigenous Tea plant in Assam; for the want of it the Dutch had imported into Cinchona a spurious and valueless plant, which they had supposed to be tea. Again, the opinion had obtained for a long time that the Latakia and Cuba Tobaccos were different from the more ordinary kinds of the weed, whereas on the seeds being examined they were found to be perfectly similar. It was now known that all commercial Tobaccos belonged to the same class. In the case of some grass brought from Jamaica the botanists were able to show, on discovering its efflorescence and seeds, that it was suitable for paper-making. There could be no more important or interesting task than to unravel the botanical mysteries of Africa, which were still to the student of nature a *terra incognita*, and in this he hoped to obtain the co-operation of the Society.

— MR. WILLS of South Kensington decorated the Charing Cross Railway Station for the RECEPTION OF THE EARL OF BEACONSFIELD on his return from the Congress of Berlin on Tuesday. Over ten thousand plants were used, many of them 20 feet high, and part of the decoration consisted of three thousand Roses.

— THE annual summer Exhibition of the CROYDON HORTICULTURAL SOCIETY was held in the Fairfield, Croydon, on the 10th inst., and is acknowledged to have been the best summer Show ever held by the Society. The productions were above the average, and amongst the principal exhibitors and prizetakers are the familiar names of Mr. T. N. Penfold, gardener to the Rev. Canon Bridges, Beddington House; Mr. Chaff, gardener to C. H. Goshen, Esq., The Ballards, Shirley; Mr. Orchard, gardener to F. W. Harris, Esq., Coombe; Mr. King, gardener to S. Clarke, Esq., Croydon Lodge; Mr. Fewell, gardener to J. C. Lanyon, Esq.; Mr. Glasscock, gardener to F. Banbury, Esq., Shirley Park; and Messrs. Roffey, Hamblin, Brice, and Charman were prominent. Both stove and greenhouse plants and fine-foliage were very extensively and admirably exhibited; in fact, the same remarks will apply to almost every class in the schedule, for it was difficult to find an inferior collection. We congratulate this Society on their success. The Exhibition has clearly shown that there are some good gardens and gardeners in the neighbourhood of Croydon.

— A LARGE proportion of the area of the Bahama Islands is devoted to the cultivation of FRUIT, of which Oranges and Pine Apples are the principal, and at the present time the fields in the estates on which the Pine Apples are growing form a peculiar feature in the landscape. The appearance of the broad expanse of young fruit, with its clusters of delicately tinted but sharp and serrated leaves, rising only a short distance from the ground, and covering the undulating fields, produces a very remarkable effect. In no other branch of agriculture can so curious a picture be produced as in the growth of these vast numbers of Pines. As many as a million and a half of the fruit have been collected from a single acre at one crop. The appearance of these Pine Apple estates has as little in common with sugar plantations or paddy fields of the tropics as with the corn fields or vineries of Europe. In a few weeks

these Pine Apples will be making their appearance in the English markets. They are shipped in an unripe state and mature during the voyage, and hence are not so excellent in quality as the English hothouse fruit, or as if they were properly ripened in the ground. The Pine Apples of New Providence, however, are superior to any other variety, and often attain an enormous size. One, grown in Pembroke-shire, weighing 10½ lbs., and measuring 10½ inches in height, exclusive of the stalk and crown, and 22 inches in circumference, was served up at the Coronation banquet of George IV., and since then the improved modes of cultivation have greatly increased the size and quality of the fruit. There is an enormous demand for the Bahama Pine Apples both in Europe and America.—(*The Colonies and India*.)

PORTRAITS OF PLANTS AND FLOWERS.

HEMANTHUS MANNII. *Nat. ord.*, Amaryllidaceæ. *Linn.*, Hexandria Monogynia. Flowers crimson.—“The leaves, as in *H. multiflorus*, grow upon a special stem, which is produced after the scape, and do not arrive at maturity until after the flowers are faded. It was gathered in April, 1861, by Mann, on the banks of the Bagroo river, but was not introduced into cultivation until last year, when it was sent to Mr. Bull from Liberia by his collector Mr. Carder. It flowered at Kew this present spring.”—(*Bot. Mag.*, t. 6364.)

FRITILLARIA ARMENA. *Nat. ord.*, Liliaceæ. *Linn.*, Hexandria Monogynia.—“The drawing was made from a living specimen received at the end of March from Mr. George Maw, who procured the bulbs from Jas. Zohrab, Esq., the British Consul at Erzeroum. We have dried examples in the Kew herbarium from the same gentleman and from two other collectors, Aucher Eloy (from whose specimens Boissier's diagnosis was made), and Huet du Pavillon. The latter localises it on the Tech-dagh above Erzeroum at an elevation above sea level of from 7000 to 8000 feet.”—(*Ibid.*, t. 6365.)

LEUCOPOGON VERTICILLATUS. *Nat. ord.*, Epacridæ.—“The great beauty of *L. verticillatus* is due to the tender rose colour of the young leaves, which appear in drooping masses surrounded at the base with rigid sheathing scales. The flowers are very minute. Sir J. D. Hooker was indebted to Isaac Andrew Henry, Esq., for a living specimen of this remarkable plant, which flowered in autumn of last year. It was raised from seed sent from Western Australia, where the species inhabits the country from King George's Sound to Swan River.”—(*Ibid.*, t. 6366.)

GRIFFINIA ORNATA. *Nat. ord.*, Amaryllidaceæ. *Linn.*, Hexandria Monogynia.—“This new Griffinia, for horticultural purposes, surpasses all the other known species with the exception of the very rare *G. dryades*. It is a typical Griffinia, most like the old well-known *G. hyacinthina*, but is much more robust in habit, with more numerous larger leaves with closer cross-veining, and larger flowers mounted on long pedicels. Like all the other species, it is only adapted for stove cultivation. It was first imported by Mr. Bull in 1875 from the neighbourhood of Rio Janeiro. In the Kew collection it flowered in February, 1878.”—(*Ibid.*, t. 6367.)

MASDEVALLIA POLYSTICTA. *Nat. ord.*, Orchidaceæ. *Linn.*, Gynandria Monandria.—“*M. polysticta* was introduced from northern Peru by M. Roelz in 1874, along with *M. melanopus* and a hitherto unfigured species, *M. caloptera*, *Reichb. f.* It has flowered in Mr. Williams' nursery and at Kew and elsewhere in the winter months.”—(*Ibid.*, t. 6368.)

CLEMATIS GREWIEFLORA. *Nat. ord.*, Ranunculaceæ. *Linn.*, Polyandria Polygynia.—“The Himalaya Mountains are the head-quarters of the genus Clematis in respect of number and variety of forms, and many of the species are of great beauty. Witness the *C. montana*, *C. graveolens*, *C. smilacifolia*, *C. barbellata*, and others not hitherto introduced, though none of them attain the size or have the beauty of colour of the Japanese species of the Florida and Fortunei set. Most of the above are perfectly hardy; this is not the case with *C. Grewieflora*, which requires a cool greenhouse, when it forms an immense rambling climber, which at Kew ascended in a few years to the gallery of the Temperate house, along the rail of which it ran for many feet, flowering profusely in early spring. The species is very nearly allied to *C. Buchanania*, also a Himalayan species, under which name it was received from the Calcutta Botanic Gardens about twelve years ago. It, however, differs from that plant in its much more dense clothing of villous fulvous hairs, as also in the shape of the leaflets. It has a very wide Himalayan range, being common towards the

base of the range from Kumaon to Bhotan, ascending to 4000 feet elevation. In Sikkim and East Nepal I found it flowering in November. A variety is found in Kumaon with almost white pubescence."—(*Ibid.*, t. 6369.)

CLEMATIS INDIVISA LOBATA.

HYBRIDS so numerous and so beautiful of this fine genus of plants could scarcely fail in causing some of the less gorgeous species being comparatively overlooked, yet many of these are highly desirable for various purposes of garden and shrubbery decoration. "Several of the more free-growing species of Clematis," says Mr. Thompson in his "Flower Garden," "are old favourites in our gardens, particularly the *C. flammula*, or white sweet-scented, which is of so rapid a growth that in a single season it will cover an arbour or trellis of some extent; and the purple *C. viticella*, a still older species, which when

Fig. 7.—*Clematis indivisa lobata*.

well managed, is one of the most elegant and ornamental of hardy climbers. Among other interesting species worth cultivating are the *C. crispa*, recently introduced from North America, with pale fragrant blossoms; *C. graveolens*, from Chinese Tartary, with yellow flowers; *C. montana*, and its variety *grandiflora*; *C. cirrhosa*, an evergreen species from Spain, with whitish blossoms, produced very early in the spring; *C. Hendersonii*, with flowers of a fine violet blue, one of the most desirable of the genus; and *C. austriaca*, *C. sibirica*, and *C. verticillaris*, three species formerly known under the name *Atragene*, but now united to Clematis. Perhaps the most showy species yet introduced is the *C. indivisa* var. *lobata* (fig. 7), with pure white blossoms 3 inches across, and bright red anthers. In its native climate, New Zealand, it quite festoons the trees for 15 or 20 feet from the ground with its dense foliage and large panicles of flowers. It is said to require a greenhouse, a statement we shall regret to see confirmed. Certain it is that some of the plants introduced into England from New Zealand require with us but little protection, unless in very severe weather."

We shall be glad to hear if this beautiful New Zealand Clematis has been successfully cultivated in British gardens.

THE PRESTON SHOW.

As far as the exhibits were concerned the Royal Horticultural Society's meeting at Preston was undoubtedly a success. The Committee's arrangements and system, however, were anything

but perfect. I, for one, quite expected to see everything carried out in the well-arranged system followed at Kensington. More especially in the vegetable and fruit tent all was confusion at Preston, as no one knew where to stage. Luckily there was plenty of space allowed or matters would have been worse. Why not have adopted the simple plan followed at Kensington—*i.e.*, to have marked out the spaces allowed for each collection, and also for the single-dish classes? Again, why follow the nearly obsolete custom of placing numbered cards only to each exhibit, instead of following the Kensington system? At the latter place the exhibitor has one number only throughout and receives a properly filled card containing name, address, class, &c., these are placed face downward with the exhibitor's number on the back: to each exhibit the Judges make their awards, which are at once entered, and in their presence an assistant places a simple prize card, turns over the exhibitor's card, and the work is done. At Preston the prize cards had all to be filled up, &c., which entailed much work, and after all was very imperfectly carried out. The Committee were very hard-working and obliging, but were far from being practical. It seems strange for the Royal Horticultural Society when holding provincial meetings to have so little to do with the management. In all probability the Local Committees little know what they undertake, or they would much rather leave to Mr. Barron and his men what to them is, if not a light, at all events not a difficult task.—EXHIBITOR.

SINGLETON ABBEY,

THE RESIDENCE OF MRS. J. H. VIVIAN.

AMONGST the many gentlemen's residences which cluster round the great commercial seaport town of Swansea none possess more horticultural interest than Singleton, with its beautiful climber-covered walls, rare Coniferae, fine fruit, and splendid situation. The house stands about two miles and a half from Swansea, and commands a delightful view of the bay, and has a background of picturesque woods and hills. It is easily reached by road from Swansea, and the visitor will not have seen much of the place until it becomes evident that originally a very great amount of good taste and prudent forethought must have been brought to bear on its construction, and it is pleasing to observe that all that has been done in the past is duly appreciated at the present time.

The house itself is of modern construction, it having been built and the whole place made by the late Mr. Vivian. The front door is surrounded with a spacious yard or wide piece of gravel, and this is belted with trees and evergreens, amongst which *Chimonanthus fragrans* and *Viburnum Tinus lucidum* have grown into conspicuous specimens. On the south front, represented in the engraving (fig. 8) there are many flower beds, grass terraces, and trees of numerous sorts. In some of the beds Tom Thumb and Flower of Spring Geraniums stand out all the year round, and they look better now than plants that have been protected. *Magnolia conspicua* and *M. grandiflora* grow luxuriantly and flower abundantly as standards.

The climbers growing against the house attract much attention. As if to throw all the others into the shade *Pittosporum Tobira* has ascended 20 feet with the same width, and it produces its lovely scented flowers in great profusion. The yellow and white Banksian Roses have grown most luxuriantly, as they are about 40 feet high and cover a large space. The Malmaison Rose has also grown about 20 feet, and so has the Lemon-scented Verbena. Flower beds abound on both the south and west sides of the house, and some of these are effectively filled with Geraniums, Calceolarias, Verbenas, &c., but many of them contain old-fashioned Petunias, Heliotropes, Carnations, and other sweet-scented flowers. Magnolias are forming fine standards on the west side of the house; *M. conspicua* has attained a height of 25 feet and the same in width.

Close to the flower beds attached to the house and elegantly draped with climbers is the conservatory, a structure 60 feet in length. It contains some fine specimen Camellias, Tree Ferns, Orange trees, and many other plants; but here there is no need to go under glass to find rare specimens of vegetation, as they adorn every nook and corner in the open air. Several of the Indigoferas are doing good service as climbers against the end of the conservatory, and so is the Climbing *Devoniensis* Rose, which flowers very freely and is never pruned or restricted in growth in any way. Many of the finer sorts of Clematis are also used as climbers. On the west side of the conservatory there are some splendid specimens of Camellias both growing in boxes and planted out in the ground. The position is rather

exposed to the sea, which is only about 400 yards away, and the winds sometimes injure the leaves of some of the trees, as is the case with some Hollies, Laurels and Bays close to the Camellias, but not a leaf of the latter has been touched, and here the Camellias are regarded as the hardiest of shrubs.

Going northwards from the conservatory by shaded walks beautifully overhung with choice trees and shrubs we come to the archery ground, a fine piece of grass, and pass on to another flower garden. There are no finely trimmed carpet beds here, but there are many features equally attractive. Round the centre fountain all kinds of sweet flowers are growing luxuriantly, and Roses hang in long wreaths from pillars. In the bed which surrounds the fountain *Yucca gloriosa* is finer than ever we saw it, and so is *Y. filamentosa*, many dense clumps of them being as much as 24 feet in diameter, and the mass of flowers which they produce has a very imposing appearance.

The lawn tennis court is situated at the end of the archery ground. Looking through a long vista of trees we find a most effective terminal group of Palms, including grand specimens of *Latania borbonica*, *Seaforthia elegans*, *Sabal umbraculifera*, also *Dracæna Cooperii* and *D. australis*. As an edging to this tropical-looking bed fine plants of *Begonia Rex* appeared to great advantage, as they were growing freely and were finely coloured. From the west side of the house a walk leads to what is called the Crategus garden, which contains fine specimens of nearly every species of the Hawthorn. Time, however, would not allow us to inspect this fine collection, and we could only look in their direction and at the same time admire the beautiful wood of Clyne and the magnificent castle of W. G. Vivian, Esq., which lay in the distance. Still going north from the house we arrive at another flower garden; but like the others there were no glaring masses of colour, the beds

Fig. 8.—SINGLETON ABBEY.

here and there being intersected with all kinds of choice shrubs, *Yuccas*, Palms, *Araucaria excelsa*, *A. Cunninghamii*, and *Cycas revoluta*. The last-named Cycad was not protected in any way during the winter, and it has thrown up many young fronds this spring. The double-flowering Cherry is a great feature when in bloom in spring, some of the trees being 40 feet high and as much in diameter. Further north and completely hid from the last flower beds there is a Rhododendron garden containing many fine plants both in size and variety. *Argenteum*, *Gibsoni*, *Falconeri*, *Dalhousii*, *Countess of Haddington*, and *Edgworthii* are amongst the leading sorts grown. Many of these Himalayan Rhododendrons that are usually grown in greenhouses are 20 feet high and as much through; they are growing luxuriantly and bloom profusely. *Azalea indica* does equally well planted out. At one end of this Rhododendron garden is a large slope arranged as a wild garden with rocks, Ferns, and wild flowers.

Leaving this and winding our way through various walks to the east side of the mansion we came to the pinetum and another large garden of Rhododendrons. Many of the shrubs here are the same as those just named, with the addition of some grand specimens of *Rhododendron Thompsonii*, *R. campanulatum*, and *R. barbatum*. All the best of the hybrids are also planted, and when in bloom in spring produce a rich effect. Ghent *Azaleas* are mingled with the Rhododendrons, and *Azalea*

mollis forms a beautiful edging to some of the beds. Many of the large Rhododendrons and *Araucarias* 25 feet high were transplanted from crowded places into more open positions last winter, and not one of them appears to have sustained the slightest check or injury. Space will only permit a few of the finest specimens of *Coniferae* being named. *Pinus Menziesii*, 60 feet; *P. grandis*, 70 feet; *P. excelsa*, 70 feet; *P. insignis*, 100 feet high, 40 feet through; *P. Morinda*, 55 feet; *P. Pin-sapo*, 40 feet; *P. Sabiniana*, 40 feet; *Cryptomeria japonica*, 30 feet by 20; *Thuja Lobbiana*, 35 feet; *Cedrus Deodara*, 90 feet; *Taxodium fastigiatum*, 80 feet. Many smaller specimens are growing plentifully, and help to constitute the finest and most extensive arboretum in South Wales.

The kitchen garden and glass houses are about 400 yards from the mansion. The houses are in three ranges, two of the ranges being span-roofed and the other lean-to houses. The vineries are six in number, and are altogether about 180 feet in length. They are mostly devoted to a single variety of Grape in each house, such as Black Hamburg, Foster's Seedling, Muscats of sorts, Lady Downe's, &c. Many of the Hamburgs were cut, plenty were ripe, some just commencing colouring, and others recently thinned. All are bearing very fine crops, and the Vines are in a highly creditable condition. In one of the back ranges Peach trees occupy an important part. Most of the early fruit was gathered, and heavy crops

of later were coming well on. At the end of the Peach range there is a large span-roofed greenhouse. Many *Maréchal Niel* Roses are planted out, and their usefulness for supplying cut blooms in spring cannot be over-estimated. The body of the house was filled with a variety of healthy plants of the kinds generally used for decoration in greenhouses at this season of the year. The next range we enter, a span-roofed plant stove, where *Caladiums*, *Dracenas*, *Begonias*, and many fine-foliaged plants are growing freely, and their high colourings are relieved with the soft green tints of many choice Ferns. Round some of the shelves *Maiden-hair Ferns* are planted out, and they do much better in this way than in pots.

The next house is a successional Pine pit containing many fine plants. Cucumbers grow along the back wall and bear wonderful crops, and at the further end from the door is a collection of Orchids, amongst them the *Aérides* and *Vandas* are particularly fine. The next house is a large three-quarter span-roofed Pine stove. Mr. Harris is regarded as the best Pine-grower in Wales. Scores of Queens were in fruit, some of them green, others ripe. Not one of them would weigh less than 4 lbs., and many of them over 5 lbs. In fact the average may safely be taken at the last figure, and those who are practically acquainted with growing Queen Pines will understand that to have scores of fruit averaging 5 lbs. a-piece is no mean achievement. Mr. Harris depends a great deal on atmospheric moisture and water at the axils of the leaves to develop the fruit properly. The soil in which they are growing contains a good admixture of peat and a little horse droppings. Moscow Queens and Smooth Cayennes were much larger than the Queens, and altogether they reflect the highest credit on Mr. Harris, who was the premier prizewinner for a single fruit at the great Preston Show.

The kitchen garden is about four acres and a half in extent, and replete with fine crops of all kinds of vegetables. The brick walls are substantial and well covered with finely trained healthy fruit trees. The Peach trees on the open walls were especially fine, and although the cold winds had injured the leaves the crops of fruit are heavy. The kinds are chiefly Royal George, Noblesse, Bellegarde, Late Admirable, and Salwey. The last named comes in very late, fruit weighing three-quarters of pound having been gathered from it on November 20th. Small fruits are a heavy crop, and Apples, Pears, &c., moderate. Mr. Harris has a comfortable house looking into the kitchen garden, and it is nearly hid with large Fig trees which generally bear heavily.

Many names and dimensions of plants and other features worthy of note have been omitted in these brief notes, but we do not think that any person could visit Singleton without coming away with our impression, that Mrs. Vivian possesses a remarkably fine garden, a gardener highly worthy of encouragement, and a conviction that this is given and fully appreciated.—VISITOR.

A GARDENERS' HOLIDAY.

ON Wednesday, July 3rd, the members of the Darlington Gardeners' Institute had their annual holiday and spent it in an excursion to Riveaulx Abbey and Duncombe Park, the seat of the Earl of Feversham. The weather was all that could be desired—bright and pleasant, without the tropical heat of the preceding week. The route was along the Malton line, running by hedges gay with wild Roses and Elders in full bloom. Coxwold, one of the prettiest villages in the North Riding, was reached. The station was worthy of the village, its garden blazing with Geraniums and other summer flowers, grouped and disposed with consummate taste, and evidently tended with loving care. Laurence Sterne was once curate of this place, where he wrote his "Tristram Shandy" and other books. As the train rushes on a good view is had of the Roman Catholic College of Ampleforth, pleasantly situated at a short distance from the village. Gilling is the next station, where a stay of twenty minutes is agreeably employed in a walk to the village and a look through the pretty country church. There are many objects of interest in it which well repay a visit. The stay was not sufficient to admit of a walk to the Castle, long the residence of the Fairfaxes. The more ancient part of the edifice is said to be of the time of Edward II.

At the pleasant quiet town of Helmsley the rail is left, and the journey is by meadows laden with huge crops of fresh-cut grass, by houses covered with Vines or garlanded by Roses, amongst which the superb *Maréchal Niel* in full bloom was conspicuous. A brief visit to the church, lately restored at

the cost of £15,000 by the Earl, and the road to Riveaulx Abbey is taken. The walk was uphill, but amply compensated by the grand prospect of Duncombe Park, surrounded by its dense woods, and the extensive and varied country, comprising a portion of the Castle Howard estate and reaching to the edge of Hambleton Moors. On by corn land and pasture, by shady woods, and down a steep grassy "bank on which the wild Thyme blows" profusely, and the little hamlet of Riveaulx, built out of the ruins, gives a pleasant halt. Riveaulx Abbey is now reached. The Abbey (or rather its ruins) occupies a romantic position in the vale of Ryedale, not far from the place where three well-wooded valleys meet, built in a deep valley surrounded and sheltered by banks clothed with ancient trees, a fit retreat for that contemplative devotion which shuns the duties and avoids the cares of active life. The ancient monks had, as the remains of their buildings show, an appreciation and love of the beautiful, and nowhere has it been more clearly exhibited than in the choice of the site for this the first Cistercian house erected in England. The nave is entirely destroyed, but the walls of the refectory and portions of the transepts, the most ancient parts of the building, and the magnificent choir, 144 feet in length and 63 in width, still remain. The latter is divided from the nave, which measured 166 feet, by a light and graceful arch 75 feet high, and has three rows of windows richly carved, but the lofty vault, framed

"To gather
And roll back the sound of anthems,"

no longer rests on the spreading arches. Roses and wild flowers grow on the lofty walls and wave in windows once gorgeous with tinted glass and pictured saints. Conspicuous amongst the wild flowers were fine specimens of the beautiful Viper's Bugloss, growing on the window sills and ruined walls at an elevation of 60 and 80 feet. One great attraction of Riveaulx is the terrace, a well-kept piece of grass half a mile long, and bordered on each side by woods, in front of which are planted various flowering shrubs. Openings in the woods offer many fine views of the ruins far below and the fields and moors above. At the head of the terrace is a Grecian temple with scenes from heathen mythology skilfully painted in fresco. Beautiful it may be as a work of art, but Venus and Vulcan, Hercules and Omphale, Pan and Cupid, have little harmony with the monastic ruins beneath and the ascetic celibates who once dwelt in them.

Leaving the terrace, the walk to Duncombe Park leads through a wood and breezy fields by the home farm, sheltered by splendid Ash trees. Here are kept the high-bred costly Shorthorns in which the Earl of Feversham takes great interest, and for one of which, the Duke of Oxford, he gave £2500. In the adjoining fields many fine animals of the same famous breed were grazing. The park, where large herds of deer were feeding, is of great extent and bordered by woods. The pleasure grounds round the hall are charming, laid out with skill and furnished with well-grown shrubs and trees. Near the hall are the north and south avenues, which afford a cool and delicious shade from the summer sun.

The great charm of the place is the home terrace, to which, by the kind permission of Thomas Parington, Esq., the Earl's agent, the party was admitted. This avenue, of the softest and greenest sward, is of considerable height above the valley, and from it grand views of the adjoining country can be had. Below, stretching into the far distance, is the luxuriant valley of Ryedale, its meadows and cornlands, its farms and cottages, basking in the bright sun of July, with glimpses of the glittering river, and in the far distance the edge of the Yorkshire wolds. Passing along a walk overshadowed by ancient Yews, some of them measuring 16 feet in circumference, Helmsley was reached. After this the ruins of the once-powerful castle taken by General Fairfax and dismantled by order of Parliament during the civil wars was visited, and then the excursionists, favoured by lovely weather and with nothing to mar the pleasures of the day, took the train home, much gratified by their visit to one of the loveliest spots in the fair county of the white Rose.—B.

EXTRACTS FROM SIR J. D. HOOKER'S REPORT ON THE ROYAL GARDENS AT KEW DURING 1877.

THE annual number of visitors to the Royal Gardens has during the past five years shown a disposition to fluctuate about an average of 670,000. Rising to nearly 700,000 in 1874, it sank in 1876 to a little below 600,000, while in 1877 it rose again to a number somewhat above the average—

687,972. As in the preceding year, the Bank holiday in August (the sixth) brought the greatest number of visitors in any one day—nearly 58,000, while on two days in January and February it sank to a minimum of twenty-four.

A proposal has been made, emanating in the first instance from the occupants and proprietors of the houses opposite, to remove the wall and substitute in its place an iron railing. This proposal I have felt it my duty to strenuously oppose. The Richmond Road is one of the great highways out of London, the traffic upon it is great, and, especially since the abolition of the toll on Kew Bridge, is increasing. The wall is not merely a most valuable and efficient screen against the driving and destructive easterly winds of spring, but it also checks the dust and litter of a great thoroughfare from being drifted into the Gardens. It has been judiciously remarked that a question of this kind must be decided from the inside. If this is done the public utility of the wall cannot be combated. It is one of the first principles of landscape gardening to conceal boundaries and produce an effect at once of privacy and interminableness. There is no better means of accomplishing this than by a wall backed by well-arranged shrubberies. If the wall be removed the wind will soon exterminate the shrubs, and the eye will rest with little satisfaction on glimpses of iron railing, passing vehicles, and clouds of dust.

Nor have the residents on the opposite side of the road any real ground of complaint. The wall existed before their houses; it effectually prevented any view into the Gardens from the ground floor windows, and the addition to its height in no way intercepts such views as can be obtained from the upper storeys. In a few years the top will be clothed as before with Ivy, while the trees planted in the Richmond Road will in course of time be a more effectual screen than any boundary wall.

My experience of the management and working of the Royal Gardens, extending now over upwards of thirty years, leads me unhesitatingly to the belief that neither the collections nor grounds can be maintained up to their present standard if the public are to be admitted in the morning. During the hours before one o'clock the labourers and gardeners practically accomplish the daily work necessary for the culture of the collections and the keep of the grounds, and in my judgment they could not do so if surrounded by visitors. At one o'clock the Gardens are "dressed" ready for the admission of the public; and though I believe our visitors are proud of Kew and deserve the highest praise for the small amount of mischief which they individually commit (apart from that which is unconsciously and inevitably brought about by the movement of large crowds), still a certain amount of depredation and wanton injury continually goes on, and our gardening staff is therefore more occupied in the afternoon with the business of protecting and supervising the collections under their control, to say nothing of answering inquiries, than of doing anything for their care and cultivation, which is indeed impracticable on full days. There is therefore a marked difference between their duties at the different parts of the day, and this division of their labour I consider it essential to preserve. It is, I am aware, proposed that this difficulty might be met by closing the houses and museums up till one o'clock. My experience, however, leads me to the belief that this, though it might be satisfactory to the local residents, would not be so to visitors from a distance. The only principle which does not lead to disappointment and difficulty is that when the Gardens are open at all they should be so in every department.

With regard to the grounds I must point out that there is this radical difference between them and any other public garden—that they are really to be regarded as an open-air museum, where specimen plants and collections of the greatest possible value are freely displayed. Here again the necessity of constant supervision during the presence of the public is obvious. Nor must it be forgotten that grounds so occupied require, unlike other public gardens simply needing to be maintained up to the same standard from year to year, constant improvement and development. The laying-out and planting of new collections, and the verification, examination, and re-arrangement of old ones, is work which must be done with the co-operation of the scientific staff, which it cannot and ought not to be expected to give during public hours.

A very large class of persons for whose use the Royal Gardens have always been primarily designed, I mean those who visit the collections with some special end in view,

whether botanists, horticulturists, students, manufacturers, &c., would have serious grounds of complaint if there were no time when they could pursue their studies in quietude. Persons with proper credentials interested in particular groups of plants are freely allowed to handle and examine them in private hours, a privilege which must be withdrawn if the public are admitted at all times. To artists, also, leave to draw during public hours is practically useless.

On Bank holidays, which are in every way days of an exceptional character, I have willingly assented to the opening at ten o'clock. On these days arrangements will be made for suspending all the work of the Royal Gardens, and the whole staff will have, even with additional assistance, more than sufficient occupation in watching and controlling the crowds.

I may mention that having had the length of walks in the Royal Gardens which have to be maintained in order carefully measured I find they amount to a total of nearly 15 miles.

The following plants of special botanical interest, amongst others of less importance, have flowered during the past year in the Royal Gardens:—*Aglaonema*, sp. n., West Africa; *Aloe tricolor*, *Baker*, "Bot. Mag." 6324; *Alpinia*, sp. n., ex. "Hort. Bull."; *Ansellia africana*, var.; *Anthurium spathiphyllum*, *N. E. Br.*; *A. trifidum*, *Olin*, "Bot. Mag." 6339; *Billbergia macrantha*, *Baker*, sp. n.; *Calamus fasciculatus*, *Howb.*; *Caralluma fimbriata*, *Wall.*; *Carludovica Plumieri*, *Kth.*; *C. sp. n.*, Costa Rica; *Ceropegia Barkleyi* *Hk. f.*, "Bot. Mag." 6315; *Crocus alatavicus*, *Regel* and *Semenov*; *C. vitellinus*, *Wahl.*; *Duvalia albo-coronata*, *N. E. Br.*; *Dyckia frigida*, "Hort. Lindl.", "Bot. Mag." 6294; *Epidendrum Sophronitis*, *Lindl.*, "Bot. Mag." 6314; *Fritillaria Munbyi*, *Baker*; *F. (Korolkowia)*, *Sewerzowi*, *Regel*; *Gasteria colubrina*, *N. E. Br.*; *Hoodia Bainii*, *Dyer*, "Bot. Mag." 6348; *Huernia reticulata*, *Mass.*; *Hypoxis Arnotti*, *Baker*; *Inula Hookeri*, *C. B. Clark*; *Ione paleacea*, *Lindl.*, "Bot. Mag." 6344; *Iris speculatrix*, *Hance*, "Bot. Mag." 6306; *Lilium cordifolium*, *Thunb.*, "Bot. Mag." 6337; *Microstylis Josephiana*, *Reichb. f.*, "Bot. Mag." 6325; *Muscari (Botryanthus) conicum*, *Baker*; *Szovitsianum*, *Baker*; *Pedicularis Hookeriana*, *Wall.*; *Phaenosperma*, (gen. n.) *globosa*, *Munro*; *Piaranthus pulsus*, *Mass.*; *Pitcairnia*, sp. n.; *Rhipsalis penduliflora*, *N. E. Br.*; *Silene Baldwini*, *Nutt*; *Stapelia comata*, *Jacq.*, var.; *S. (Gonostemon) erectiflora*, *N. E. Br.*; *S. (G.) glandulifera*, *Mass.*; *S. (Orbea) namaquensis*, *N. E. Br.*, var.; *S. grandiflora*, var. *lineata*, *N. E. Br.*; *Tillandsia usneoides*, *L.*, "Bot. Mag." 6309; *Tovaria oleracea*, *Baker*, "Bot. Mag." 6313; *Tulipa undulatifolia*, *Boiss.*, "Bot. Mag." 6308; *Xanthorrhoea minor*, *Br.*, "Bot. Mag." 6297.

CHAPTERS ON INSECTS FOR GARDENERS.

No. 22.

ON seeking a definition of a "moth" from ordinary persons not particularly observant of Nature (but avoiding those who apprehend that a "moth" can only be some such insect as that well known for its attacks upon clothes), we find that we get very various replies. A tolerably common one would be to the effect that a moth is a duller-coloured insect than is a butterfly, with a stout body and a propensity for hiding by day, taking excursions after darkness has set in, on what object intent, however, opinions will greatly differ. Viewed as a general idea of the moth tribe this is not a particularly successful attempt, yet it would apply tolerably well to the family of the *Noctuid*, a large group in Britain, embracing about three hundred species, though we are thrown into the shade by the enormous array that the Continent of Europe presents to view, where *Guerée* has described nearly nineteen hundred species!

In this family are found some caterpillars that are exceedingly troublesome in gardens, attacking culinary plants chiefly, but it does not follow from the figures just given that foreign horticulturists have six times as many of these pests to contend with, because the vast majority of these *Noctuas* feed, when caterpillars, on the roots, stems, or leaves of plants and trees that are not of special importance to mankind. Yet it is the case that in such countries as France and Italy insects pass through their transformations more rapidly than they do in

these islands, and where we should have but one annual brood of a species, abroad there may be two or three broods. Gardeners in the course of their digging during the winter destroy often, without being aware of it, a goodly number of the pupæ of the Noctuidæ, for a great many species live from autumn to spring in that stage at a depth of from 2 to 6 inches in the earth, and therefore are liable to injuries from the spade or fork. Some, however, have the caution to place themselves close to a fence or in the angles formed by roots, or in other positions of partial shelter. Thousands of these pupæ furnish an agreeable article of food to ants and to the predacious larvæ of certain beetles; indeed, in the case of any caterpillar that we may notice in the act of going down for his change to pupa the chances are considerable against his making a re-appearance as moth.

From the Geometrine group, already commented upon, the Noctuidæ are distinguished not only by their stout bodies but by the circumstance that when the moths are reposing the fore wings, which are narrow usually, cover the hind wings by these folding-up under them. The fore wings do not resemble the hind wings, and they have in their centre two spots of an eye-like appearance, varying much in size and tint, one being called the "orbicular discoidal spot," the other the "reniform discoidal spot." All these moths are provided with a stout tongue or maxilla, which coils up spirally, and which at night enables the insects to feast on the nectar of flowers. Attracted by their perfumes many of the Noctuidæ fly from the fields and woods into our gardens. As they hover above the blossoms their eyes frequently shine like tiny stars, the cause of which may be phosphorescence, but we do not precisely know. The caterpillars are mostly smooth-skinned and of dull colours. The Acronyctas, however, or "Dagger Moths" have caterpillars as thickly clothed with hairs as are those very familiar Arctias in the Bombycina family, and which are commonly called "Woolly Bears." A few species, among which is the Gamma Moth or Silver Y (*Plusia Gamma*), have not the full complement of legs in the caterpillar state, in consequence of that fact they move when crawling somewhat in the Luper fashion. To enumerate even a tithe of the common species amongst the Noctuidæ would occupy too much space here, and it will be in accordance with our design in this series to indicate those species merely which to gardeners seem the more important from the rapacious habits of the caterpillars.

Obviously we have few friends amongst them; we cannot say we have none, for the caterpillar of the Dun Bar (*Cosmia trapezina*), though it can eat the leaves of trees, is fond of devouring the troublesome caterpillars of the Winter Moth (*Cheimatobia brumata*), that also of the Satellite (*Scopelosoma satellitia*) has similar tendencies, but it is not quite so ferocious. We have not yet heard it recommended that these cannibals should be encouraged in gardens, where they occasionally appear, though more common in woods or lanes. These excepted, Noctuid caterpillars feed on vegetable substances. Some attack specially roots or the subterranean stems, and do a great deal of mischief ere it is observed. This large group is again subdivided. In some families few or none interfere with horticulture; the numerous species called "Wainscots," for instance, mostly live while in the caterpillar state upon Grasses or Sedges, but the moths may fly some distance from the place where they were bred. On many garden walls scores of the pretty little moth, the Marbled Beauty (*Bryophila perla*), may be seen in July or August, but they have never had to do with leaf or flower; the caterpillars thrive on the small lichens which commonly cover old brick or stonework.

The hairy caterpillar of *Acronycta Psi* (rather absurdly called the Grey Dagger, for several of its brethren are just as grey) feeds on fruit trees as well as on the Limes and Elms in our shrubberies. It is easily recognised by the yellow stripe down the back and the straight lump on the fifth segment. Like the rest of the Acronyctas it spins a cocoon when adult, choosing a crevice in the bark of a tree or a crack in some paling. Another species feeding on the Alder (*A. Alni*), and having a caterpillar with curious appendages on each side like flattened horsehairs, is so rare that specimens have fetched 15s. each. A very determined hunter after sweets either natural or artificial is the Moth of the Dark Arches (*Xylophasia polyodon*), and when swarming about gardens these insects have occasioned needless apprehensions, for they do not deposit eggs in such situations; the caterpillars are indeed subterranean devourers, but they attack plants in fields and waste places. The caterpillar of the Anther (*Chareas graminis*) is noteworthy, because in France and Sweden it has in

some seasons laid waste much of the grass land; it has not however, as yet proved a serious enemy to our farmers. But the caterpillars of the Rustic Shoulder-knot (*Apamea basilinea*) do destroy when they are young more of the grain of Wheat than is agreeable to those who have stored it ready for thrashing, the moths laying their eggs in June on the ears. Of all the Noctuidæ it is likely none is as well known and as sincerely disliked as is the Cabbage Moth (*Mamestra Brassicæ*), which in activity and artifice excels the Cabbage Butterfly by far, and by no device can it be excluded from our gardens. There appears to be but one yearly brood, the moths emerging in succession, so that we find in our plants caterpillars of different ages in the same month. Not satisfied with the revels they have amongst the Brassicaceous plants of the kitchen garden, many of these wander insidiously into the flower garden, hiding by day to regale by night on Geraniums, Dahlias, and a variety of plants. Near akin to this, yet less common, is the Dot (*Mamestra Persicariæ*), the greenish-brown caterpillar with V-shaped markings, feeding openly, is a frequent mark for the birds, and also readily found by the gardener. It occurs in both the kitchen and flower garden, and at times upon Lilacs, Elders, and other shrubs. Oddly enough it is unknown in Ireland, where *M. Brassicæ* is as abundant as in Britain.

A near competitor to the preceding in its powers of doing damage to vegetation is the caterpillar of the Turnip Moth (*Agrotis Segetum*), nor may we presume from the name that it confines itself to that esculent, for the juvenile individuals have a penchant for attacking young Cabbages and Carrots just at the surface of the ground; moreover beds of China Asters have exhibited hundreds of drooping plants, a testimony to the "deeds of darkness" of which the insects have been capable. "It is tedious work," says Mr. Newman, "looking for the mischief-maker at night with a lantern, and awkward to dig between the plants; some gardeners therefore sprinkle lime, or sawdust, or soot, or ashes, or salt, or ammoniacal liquor on the ground, but the result is far from certain, and therefore unsatisfactory." The species was particularly common in 1864, and it was then pointed out by this same entomologist that by our foolish discouragement of several birds, especially the rook and the starling, we had increased the numbers of the detested "Turnip grub." Also common and injurious to similar plants is the caterpillar of the Heart and Dart (*A. exclamatoria*), which doubtless causes not a few gardeners to utter exclamations of disgust. The dingy brown caterpillars of the two species are so much alike that even entomologists are puzzled to distinguish them. A larger species than the preceding, and which in the moth state often enters houses and public buildings, dashing at the lights, is the Yellow Underwing (*Tryphæna pronuba*). It has a caterpillar very variable in colour, of velvety texture, and which conceals itself during the day to feed on Cabbages, Lettuces, and other plants after dark. As the caterpillar life is continued from autumn to spring this species does damage at a time when many of its brethren are in a state of quiescence.

Passing by a host of Darts, Rustics, Clays, Quakers, and allied species, some of which are handsome and rare, we stop at that striking moth the Angle-Shades (*Phlogophora meticulosa*), noticeable on fences in May or September, the rather leech-like green-and-white caterpillar of which feeds on several garden flowers in summer, and in winter contents itself with such wild plants as the Groundsel. It is not so prolific as to be specially injurious. Then there is a Noctua that is particularly attached to the common Brake Fern, though named from the Broom (*Hadena Pisi*). I have seen Ferns nearly stripped in the vicinity of London by the beautifully striped caterpillar of the species. The Early Grey (*Xylocampa lithorhiza*) has a fancy for the Honeysuckle, on which the caterpillars occur from June to August. Amongst other species bearing the mark which is compared either to the letter Y or the Greek gamma, the Silver Y (*Plusia Gamma*) is remarkable for its habit of flying in the daytime; nor does it appear to require rest at night, for specimens will assemble at sugar spread upon trees. The moth is as much at home on an extensive common as within the walled precincts of a garden, and the caterpillar is not critical with regard to food, though preferring plants of low growth.

An oddly named moth, the Gothic (*Nania typica*), has a caterpillar whose habit it is to feed in small companies of from ten to twenty upon the leaves of fruit trees. I have also observed them on the Chrysanthemum. In about a month they descend to feed on Lettuces, Mint, and various herbaceous

plants, hibernating to re-appear in the spring. One of the largest of our Noctuidæ, and one of very dull tint, is called the Old Lady (*Nania maura*). The caterpillar, which is necessarily of good size, is reported to feed on fruit trees, also on the Strawberry, but it is seldom seen. The moth is partial to outhouses, where, large as it is, it sometimes falls a prey to spiders. The last species that we can specify is the Mouse (*Amphipyra Tragopogonis*), so styled from its mode of shuffling along when alarmed, the caterpillars of which occasionally feed on Larkspurs, more generally upon the Whitethorn.—J. R. S. C.

WORK FOR THE WEEK.

FLOWER GARDEN.

FLOWER beds require frequent looking over for the removal of decayed leaves and flowers, and for pinching-in the growths so as to keep the marginal and divisional lines of the various patterns clear and distinct. Seed pods of *Pelargoniums*, *Verbenas*, *Violas*, and all plants employed for bedding should be removed immediately the petals fall, as the production of seed tends to weaken the plant and impedes its continuous flowering. *Verbenas* and *Violas* should not only have the seed vessels removed frequently, but have the branches moderately thinned and pinched back so as to induce young growth, thereby securing continuity of flowering. *Calceolarias*, *Violas*, *Verbenas*, and all plants delighting in moisture should have water abundantly in dry weather, avoiding giving it overhead, as it impairs the beauty of the flowers, especially those of *Calceolarias*, which from their form fill with water and fall off. Carpet-bedding plants of free growth must be kept pinched, so that the lines forming the various designs be kept clear and distinct, as these beds owe much of their effect to their trimness.

Dahlias, *Hollyhocks*, and all plants having a large leaf-surface should be timely staked and have their growths well secured, so as to prevent them from being broken or damaged by winds. Similar remarks apply to subtropical plants, which with *Dahlias*, *Hollyhocks*, &c., should have liberal supplies of liquid manure, especially in dry weather. *Asters*, *Phlox Drummondii*, and other annuals should also receive copious supplies of liquid manure, and if extra large flowers are wanted the flower buds must be freely thinned. *Gladioluses* should have copious waterings in dry weather, and have a mulch over the surface of the soil of short manure, which will not only have an invigorating tendency, but will keep the soil cool and moist, which is of no little consequence in light open soils; in heavy soils the mulching keeps the surface from cracking.

Roses will be greatly benefited by free application of liquid manure and thorough mulching, which will help them to push fresh growth and keep up a good successional bloom. Continue removing the faded flowers, and check any straggling rampant shoots by cutting back, so as to retain order and regularity in the form of the heads, and to equalise the sap, preventing undue vigour in one part and weakness in another. Push on the budding whilst the stocks are in good condition, and continue inserting cuttings under handlights on a north border, or in a gentle hotbed.

Seeds may yet be sown of biennials and perennials, paying attention to pricking off plants produced by a former sowing as they become large enough to handle, for they do not have a chance to become stout and well furnished when allowed to remain thickly together in the seed beds.

In "dressed" grounds a variety of trees and shrubs enter into the arrangement, which without free use of the knife are not in keeping with the trimness that pervades the surroundings. To keep such evergreens as common and Portugal Laurel, &c., in anything like presentable form severe spring pruning is not more important than a judicious removal at this season of irregularities of growth, so as to afford the desired shape of the specimens or outline of the groups of which they form part, but any stiffness, such as that likely to result from clipping with the shears (which greatly disfigures the leaves by severing them), should be avoided.

There can be no doubt that the present is much the most preferable time of year to operate upon choice trees and shrubs needing assistance in the formation of symmetrical heads by the shortening back of straggling branches or removing altogether those that cross each other, for at this season the wounds caused by cutting off the branches heal much more quickly than at any other period of the year. Many fanciers of fine trees, notably coniferous trees, are averse to the knife or saw being employed upon them, alleging that trees left to assume their own natural forms are preferable to those receiving aid from man, to which we cordially subscribe, except always when two leaders start away and contend for chief place it is of importance that one of them be removed, also that irregularities of growth be checked, so as to aid Nature to produce the finest specimens of her works.

FRUIT HOUSES.

Pines.—Plants started early in the year for fruiting will now in the case of early sorts have ripened-off the fruit, and the later kinds will be so advanced in ripeness as to admit of their being

removed to a vinery or other house rather cool and dry, to finish off, which will have the advantage of prolonging the season and admit of the successional plants being afforded more room, it being impossible to have fine fruit unless the plants have plenty of room and light to induce sturdy habit. Let there be no delay in getting in the suckers from the early-fruited plants, potting them in fibrous loam rammed firmly into the pots and around the base of the suckers, watering at once, having in readiness a bed of fermenting materials at a temperature of about 90° at the base of the pots to plunge them in. They root best in a close moist pit. In plunging bring the material over the surface of the pots so as to prevent the soil becoming dry near the top; the soil will then have sufficient moisture until the suckers have rooted, they doing so more quickly if shaded from bright sun and ventilated a little at 85°. Care must be had in not subjecting the suckers to too strong bottom heat. Beds that had a supply of fresh material in spring will not require any now. They may, however, with advantage be turned over to a depth of 20 to 24 inches, but those that had not a renewal of the material in spring should have an addition of about a foot of new tan mixed with the old to a depth of 18 inches, avoiding if possible the making of new beds, but if it be necessary 24 inches in depth of new tan will afford all the heat necessary for the suckers.

Figs.—Those ripening-off the fruit must have a circulation constantly of dry warm air to produce it in the highest perfection, which can be secured at this time of year without resorting to artificial heat except in dull cold weather. The second crop will be advanced in size; and if the fruit be too thick it must be thinned if not already done, remembering that this crop must not tax the energies of the trees too severely if the trees are expected to afford early fruit next season. Attend to stopping and tying-in the shoots, watering the borders copiously, especially those of limited area, and syringing forcibly twice a day to keep red spider under. Do not neglect to syringe trees in pots intended for early forcing at least once a day, in hot weather twice, affording liquid manure at the roots, and pinching to induce fruitfulness in young plants. Stopping must be regulated by the vigour of the plants and kind. Vigorous growers will need to be more closely pinched than those of moderate growth. Such kinds as Early Violet, Black Ischia, Bordeaux, Negro Largo, White Ischia, Ciel de Perdrix, and White Marseilles are of good habit and do not require such close stopping as Angelique, Brown Turkey, and others of more vigorous growth. It is important that the trees have plenty of light, are not crowded, and are well ventilated to solidify the growth as it is made.

Melons.—Plant without further delay in the Melon house for producing fruit in October, and sow seed at once to raise plants to ripen a crop of fruit in November. In Melon houses artificial heat may now be dispensed with, except when dull cold weather prevails when the fruit is setting or ripening. Syringe growing plants freely in the afternoon at about 4 P.M. or earlier, allowing the temperature to rise, but not above 85° to 90° after closing. Afford a plentiful supply of water at the roots, when shading of the foliage will seldom be needed. The latest plants in pits and frames will now be setting or far advanced to setting their fruit, it being important that the fruit be set at the close of this or early part of next month to allow time for its swelling and ripening. Give a good watering before the flowers open, line the sides of the beds with some hot dung or short grass, and leave about three-quarters of an inch of air on constantly at the back of the lights until the fruit is set and commences swelling, then keep the growths well stopped and maintain a warm moist temperature by early closing with sun heat, and sprinkling the foliage, and watering in bright weather twice a week.

Cucumbers.—Pot off the plants for autumn fruiting, pinching out the growing point beyond the second rough leaf, and complete the preparation of the dung for affording bottom heat, presuming fermenting material to be employed, and have the soil in readiness for planting in due time. The house must have a thorough cleansing after the old plants and soil have been removed. Although fire heat is at this time of year in bright weather unnecessary, yet in a prolonged period of damp dull weather the nights are cold, and the low temperature induces yellow fruits, canker at the collar of the plants, and mildew on the foliage. In such weather employ gentle fire heat by night, and day also if cold. Against mildew flowers of sulphur dusted freely about the foliage is an infallible remedy, and against canker there is nothing better than rubbing the infested parts until dry with freshly slaked lime. Upon a return to bright weather after a dull period shade from bright sun to prevent flagging, which if allowed wastes the energies of the plants, resulting in ill-shapen stunted fruits, and offers a strong inducement to red spider.

PLANT HOUSES.

Orchids.—Many of the *Masdevallias* and *Odontoglossums* will now require a shift, especially those that are growing strongly and have filled the pots with roots. Keep the temperature in the *Odontoglossum* house cool by sprinkling plenty of water about the floors, and ventilate freely. The bottom ventilators should be left open all night, using the syringe freely. This is a good time to pot *Cattleya Mossiæ* and *Lælia purpurata*, as these will have

started into growth. Cattleyas when growing freely require plenty of moisture, which will enable them to make good plump pseudobulbs. Ventilate the houses at about seven in the morning, closing at about four in the afternoon. As many plants will have completed their growth they should be removed to a cooler house with an average temperature of about 60° without sun heat, it being less charged with moisture and heat than that in which the growths were made. When continued in their growing quarters a majority of the plants start into second growth, which, as a rule, does not become properly matured. Afford weak liquid manure to Calanthes and keep the leaves freed of red spider, thrips, and scale by sponging with soapy water and afterwards with clear soft water. *Thunia Bensoniæ* and *Thunia albus* come in about this time when flowering plants are waning, and are therefore the more valuable, and being of easy culture should be grown in every collection. They require similar treatment during growth as *Calanthe vestita*. *Sobralias* are subject to red spider, and should be frequently sponged and syringed. Syringe all blocks and plants overhead, especially after a hot day, giving plenty of air to all pseudobulbous plants to enable the growths to become ripe and solid. *Anæctochilus* when growing and in good health should have plenty of water; those under bellglasses should have a crock placed so as to tilt the glass to admit air, which if not attended to the plants are liable to damp off. It is a good plan to remove the glasses every morning early for two or three hours.

Stove.—Plants of *Eucharis amazonica* that flowered early will now have made a good growth, and should have water withheld until the leaves commence flagging, then give a little to restore the foliage, keeping the plants in a light cool airy house for about five or six weeks, when if returned to heat and moisture they will soon throw up the flowers. *Anthurium Schertzerianum* after it has ceased flowering should, if required, be shifted into larger pots. Being a surface-rooting plant it does not require a great depth of compost to grow in, but must have very liberal drainage, as the waterings require to be abundant. Good fibrous peat in lumps as large as eggs, some sphagnum and charcoal or crocks moderately small and a free admixture of sand, removing all the earthy portion from the peat by shaking in a sieve, form a suitable compost. Attend to climbers with water and liquid manure, especially those planted out, as when the borders are dry red spider thrives famously upon the foliage notwithstanding that it be syringed. Fires may for the most part be dispensed with, but in a dull cold period they should be called into requisition; for notwithstanding that the plants may not immediately show any of the effects of cold, they will do so all the more markedly when subjected to warmth again, whether it be natural or artificial.

TRADE CATALOGUES RECEIVED.

Jules de Cock, Faubourg St. Lievin, Ghent, Belgium.—*Catalogue of Specialities of Hardy and Tender Ornamental Plants and Trees.*

George Brunning, St. Kilda Nurseries, Brighton Road, near Melbourne.—*General Catalogue of Plants, Flowers, and Trees.*

TO CORRESPONDENTS.

* * All correspondence should be directed either to "The Editors," or to "The Publisher." Letters addressed to Mr. Johnson or Dr. Hogg often remain unopened unavoidably. We request that no one will write privately to any of our correspondents, as doing so subjects them to unjustifiable trouble and expense. Correspondents should not mix up on the same sheet questions relating to Gardening and those on Poultry and Bee subjects, and should never send more than two or three questions at once. All articles intended for insertion should be written on one side of the paper only. We cannot reply to questions through the post.

CARNATIONS BURSTING (*Amateur*).—They are too well fed. A poorer soil and less water would enable all the parts to develop equally.

ROSES (*A Lover of Rose Shows*).—There would be no difference in the hardness of the plants.

BEAUTY OF TROWBRIDGE FUCHSIA.—We are informed that it was raised by Mr. J. Smith of Trowbridge.

GREENHOUSE ASPER (*T. K.*).—Facing the south with one end open to the east will not be objectionable for your greenhouse.

BEGONIAS (*T. B.*).—The varieties are a legion and not nameable.

SOWING SEED OF ECHEVERIA SECUNDA GLAUCA (*M. B. S. D.*).—Sow the seed immediately upon fine well-watered soil in large pans, which cover with some opaque substance to exclude light, and place in a pit or greenhouse. Inspect the pans occasionally, and as the seed vegetates admit light, and prick-out the seedlings thinly in other pans as soon as they are large enough. You do quite right to shade your *Geraniums* sent by post. The loss of the foliage is attributable to the exhaustive effects of such a method of transit.

VINES FOR A SMALL VINERY (*W. C. B.*).—According to the common method of procedure three Vines would be planted in a house 12 feet long; but as your house is only 8 feet wide we advise you to rest content with your one Vine of Black Hamburgh, planting it in the centre of the front of the house, and training three rods or canes from it up under the roof, and

thus secure a much more vigorous root-action than you could do if more Vines were planted. If your light, rich, friable loam is well drained, you may plant your Vine in it next November without any other preparation than a dressing of manure to be forked-in just as for a crop of Cabbages. Afterwards when the Vine is established and its roots have traversed the border from back to front, as they are quite certain to do in a year or two, apply surface dressings of manure, but avoid forking the border or the roots will sustain serious injury.

TRANSPLANTING RASPBERRY CANES (*Idem*).—Do not attempt to transplant your old Raspberry stools, but select stout young offsets in the autumn, cutting them back to 2 feet and planting them about 2 feet apart in well-manured soil. Retain the old bed till the young plants throw up strong canes, which they will do the first season in very rich soil. Plentiful waterings of sewage or liquid manure tend materially to promote that early strong growth which is so desirable.

YOUNG GRAPES WITHERING (*J. Williams*).—Remove 3 or 4 inches of the surface soil, then apply mulch, keep it on during the growing season, and water so as to keep the soil moderately moist. Your object must be to encourage by every possible means the emission of surface roots, and when you achieve this your Vines will improve. Perhaps your Vine border requires draining.

KITCHEN GARDEN FOR A SMALL FAMILY (*S. S.*).—Under good culture a dozen square perches of ground would afford you the quantity of Potatoes you require. Figures may be made to prove anything. Here are some for you. A bushel of Potatoes weighs 56 lbs., and land that is moderately rich will yield 2 bushels of large Potatoes from a square perch. A quarter of an acre of ground would probably supply you with other vegetables. So much depends, however, upon the nature and condition of the soil, upon the treatment it receives, and upon your requirements that it is impossible to be more explicit, for if you require a large supply of vegetables and a succession of such as are usually grown in large gardens double the area of land would not be too much.

DISEASED CUCUMBERS (*New Subscriber*).—Some notes on Cucumber culture are in course of preparation, and will shortly be published.

VINE LEAVES DECAYING PREMATURELY (*C. D.*).—No doubt the premature decay of your Vine leaves is owing to imperfect drainage. Why your border is so much below the level of the garden surface you do not state. If this cannot be altered and the border raised, then sink a shaft or make a tank close outside the lower end of the border, into which drain all superfluous water. The small size of the leaves you sent us betokens want of vigour, apply therefore a heavy top-dressing of rich manure from the stable or farm-yard immediately; see also that no more time is lost about the drainage, and then you may reasonably look forward to a better state of things next year.

ROSE FOR AN EAST ASPECT (*H. F. C.*).—As you require a Hybrid Perpetual for your fence we suggest climbing Countess of Oxford, but *Gloire de Dijon* is much preferable; no Rose is more hardy, and few are equal to it in robust vigour of growth and the still more important merit of continuity of flowering from early summer till late in autumn.

JAPANESE ROSE (*Somerset*).—Yours is the true Japanese Rose, *Rosa rugosa Regeliana*.

MAIDEN BLOOMS FROM SEEDLING BRIAR (*A Lover of Rose Shows*).—We think that they are not equal to those of the standard or Manetti. They come later and are very large, but not of so good form as the others. We see no advantage in having standards 5 or 6 feet high, though often some of the best sorts of Teas are budded on them. They require longer stakes and are less secure in gales of wind. They certainly are very fine when budded with varieties which, like *Maréchal Niel*, are inclined to weep. Perhaps the buds usually grow more freely on the high standard.

COLEUS LEAVES EATEN (*J. C.*).—A very small caterpillar often attacks *Coleuses*. It is very difficult to find, being nearly of the colour of the leaves. Shake your plants sharply over a sheet of paper, or examine them closely by candlelight, and you may find the marauder. There are so many varieties of *Coleus* so much alike that we cannot with certainty name from leaves only. As to form of plants for exhibition that is entirely a matter of taste. Adopt the form which you can best carry out.

NAMES OF PLANTS (*J. H.*).—*Lilium umbellatum*.

THE HOME FARM:

POULTRY, PIGEON, AND BEE CHRONICLE.

MEETING OF THE ROYAL COUNTIES (HANTS & BERKS) AGRICULTURAL SOCIETY AT SOUTHAMPTON.

(Continued from page 38.)

HORSES FOR AGRICULTURAL PURPOSES.—Class 17.—This is an important class for the conductors of home farms, and whether the horses are reared for sale or for work on the farm, it is of great consequence that the best style of animal should be selected. The first prize for the best cart stallion foaled before the year 1876 is awarded to a powerful Clydesdale belonging to Messrs. Stanford Ashurst, Steyning, Sussex; Mr. Stratton of Chilcombe, near Winchester, being a good second with a beautiful well-bred dark grey. In this class there were twelve entries. Class 18, for younger stallions, the first prize is taken by Mr. G. Newland of Micheldever, Hants. Class 19, for the best gelding or filly the Messrs. Stanford are again first with a capital Clydesdale filly, descended from his celebrated horse "Duke." Classes 20 and 21, for the best entire cart colt and filly respectively, were well contested by well-known breeders with superior animals. Class 22, for the best mare and foal, eight entries.—This was a splendid

exhibition, every animal shown being worthy of high commendation, Messrs. Stanford, however, taking first honours with a most powerful Clydesdale mare and foal. Class 23, for the best mare for breeding purposes, twelve entries.—Messrs. Stanford were again successful against a strong competition, Her Majesty the Queen being a competitor in this as well as several other of the classes. Taking the show of agricultural horses altogether it was worthy of study, and we particularly noticed that no animal had any chance of receiving an award from the Judges unless it was not only large and powerful, but the Clydesdale was always preferred as stock for the cultivation of the land, they being not only heavy but extremely active as well.

Cattle (Shorthorns).—This noble breed of cattle, alike advantageous, being profitable as well as ornamental for the park or home pastures, was not very well contested as to numbers at this Show. Class 29, for the best Shorthorned bull.—First prize was awarded to Mr. J. Proud, East-end Farm, Lymington, Hants, and in this he gains a great victory with a white bull of rare shape and quality over the other competitors, but especially as opposed to Mr. Joseph Stratton of Alton Priors, Wiltshire, who takes second honours with a magnificent animal of extraordinary weight and of full pedigree. The other bulls in this class were all commendable animals, reflecting great credit for the judgment displayed by their owners. Class 31 and 32, for bull under two years old and bull calf, were contested by five and seven entries respectively, the chief honours going to Mr. J. Stratton, Rev. R. Kennard of Marnhull, Blandford, Dorset, and Col. Loyd Lindsay, M.P., Lockinge Park, Wantage, Berks. Although there is nothing particular to notice in these animals, yet they were meritorious stock and full of promise for the future, especially the Rev. Mr. Kinnard's calf from his celebrated cow "Queen Mary." Class 33, for the best cow in calf or in milk, seven entries.—This class is remarkable for the value and beauty of all the cows shown. The first prize is awarded to Col. Loyd Lindsay for a well-bred cow which we cannot find fault with, except that we do not consider her a great milker; she is, however, well bred, of full pedigree, a good handler, very fat, and covered with soft mossy hair. The second prize is awarded to the choicest dairy cow in the yard without a name or pedigree, but belonging to Mr. H. C. Dorrington of Boyat Farm, Otterbourne, Hants. This cow has a calf by her side a month old, yet she shows excellent condition, is an extraordinary milker, and we think ought to have received the first prize because she is everything that can be wished for as a dairy cow, possessing all the points required of the Shorthorned breed; whereas the first-prize cow in our opinion is only calculated to rear stock for show purposes, or for calves to be steered and sold as "baby beef." Mr. Dorrington's must be therefore considered a great victory in such a noble class of cows; and although he is only placed second, yet in all our experience we have never seen a greater triumph of intelligence connected with dairy management. Class 34, heifers under three years old, three entries only, yet the first prize, taken by Mr. R. Browning of Old Alresford, Hants, is an animal which would stand well in a numerous class; she is, however, too fat for breeding purposes, and we would have the owner bear in mind that the greatest of drawbacks in Shorthorned breeding are barrenness and abortion, produced, as we believe, from over-feeding, which often mars or destroys the productive powers, and it is much to be regretted that the fashion of the day for high feeding (particularly that of allowing young stock to take milk from nurse cows up to twelve or fifteen months old) prevents many of our best breeders from exhibiting some of their most valuable females. Class 35 and 36 have eight and seven entries respectively, and although the stock here is really good it does not require from us, in the interest of the home farmer, any special notice, there being no improvement upon former shows. In concluding our remarks upon Shorthorned cattle we wish to say that as there has been no real improvement in the breed of Shorthorned cattle, whether for the production of beef or milk, since the time when "Master Butterfly," belonging to the late Col. Towneley of Lancaster was exhibited at the Royal Society's meeting at Canterbury in 1856, that being the best bull we have ever seen for getting stock adapted to all purposes. It is now, therefore, desirable to purchase only animals of full pedigree, which are celebrated especially for the milking capacity, and every other requirement will follow as a matter of course. As space will not at present allow us to remark upon the Longhorns, Devons, Herefords, and Sussex classes, although some points of interest must be omitted, we will pass on to the Channel Island cattle, hoping in our usual weekly article to refer to all the others in due course.

Channel Island Cattle.—This is certainly one of the best exhibitions in quality and numbers we have ever witnessed within our recollection at the meetings of the Royal Society or any other; and as this stock is more fashionable than ever as furnishing both profitable and handsome ornamental stock for the parks and pastures of the mansions and villa residences of the suburban and other districts, we must give a prominent notice of them upon this occasion. The "little beauties," as they are called in this neighbourhood, are great favourites, and certainly attracted more attention (especially from the ladies) than any other stock exhibited.

Class 56.—The first prize is taken by a capital specimen of the Jersey breed, belonging to Mr. J. Cardus of Town Hill, West End, Southampton. He is just under three years old, and is as near perfection as any bull we have ever seen, being also of the fashionable silver-grey colour. The second prize was given to Mr. T. Hepburn of Clapham Common for a fine large animal of a light silver-grey colour; he was, however, double the age of the first-prize bull. Three commendations were awarded in this class, one of which was to the celebrated Mr. G. Simpson, of Wray Park, Reigate, and it is the greater credit to the winners of these prizes that Mr. Simpson should be left in the commended rank.

Class 57, Bulls under two years old, twelve entries.—First prize to Mr. G. A. Fuller. This is a prime animal of good outline and character, and is nearly equal to the first-prize in the former class. Second prize goes to Mr. Simpson for a light silver-grey, showing the good breeding peculiar to this stock, and well deserves the second prize.

Class 58, For the best bull calf.—Mr. Simpson first prize, and Mr. J. F. Burrell, of Frimley, Surrey, second prize. The eight entries in this class all promise well for the future of this breed.

Class 59, Thirty entries, for the best Jersey or Alderney cow in calf or in milk.—Mr. Simpson in this class takes the first prize, two extra, and a third prize, the first prize being awarded to "Luna," an animal of a light fawn colour, the winner of the first prize also at the Bath and West of England Society's Meeting at Oxford. She is certainly the choicest cow of the breed we have ever seen; she shows great absence of flesh, which is one of the proofs of her extraordinary milking capacity. Nos. 315 and 316, shown by the same breeder, are exquisitely beautiful cows of a light fawn colour. Mr. H. A. Rigg takes the second prize with a nice handsome cow, and evidently a profuse milker. In this class Mr. Cardus obtains a high commendation. He is also commended for a good cow of silver-grey colour. Mr. C. B. Dixon, who is a very careful breeder of Jersey stock, obtains two commendations in this class with very good and well-bred cows. Mr. C. Purrott of West End, Southampton, has a really good dairy cow of this breed commended. This class as a whole, taking the number shown and their extremely nice quality and condition, has never been equalled in any show we have ever seen; this, however, was to have been expected in a neighbourhood where so many are kept, and Southampton being the chief importing town for this stock direct from the Channel Islands.

Class 60, For the best Alderney or Jersey heifer under three years old, twenty entries.—This is an extremely handsome array of promising heifers, but the choicest received the prizes, Mr. Rigg being first, Mr. Simpson second, and Mr. Fuller third, with a high commendation to Mrs. Malcom, Beechwood, Lyndhurst, Hants—in fact this class was so beautiful that we should have commended the whole had we been judge at the Show.

Class 61, For the best heifer under two years old, eighteen entries.—Here again we have very pretty row of stock, showing exceedingly well for future excellence in the dairy. The first prize to Mr. Simpson, second Mr. Rigg, Mr. C. Dixon taking an extra prize and high commendation, and the same to Mr. J. Cardus.

Class 62, For heifer calves.—This is an interesting class, and promises in the future to maintain the celebrity of the Channel Island stock, not only for beauty but for profit in the dairy. Mr. G. Simpson is again to the front, and has the honour of placing Her Majesty in the secondary position, the second prize only having been awarded to the stock from Osborne.

In the Class 63, for the best Guernsey bull, only two entries, the first prize going to Major Mackay, Lyndhurst; the second to Mr. G. H. Errington, Merry Oak, Southampton. Both these were good animals, but they do not find much favour in this district, the breed being more generally used (on account of the extremely yellow and rich milk) for colouring the butter or cheese where poor milk prevails.

Classes 64, 65, 66, and 67, for Guernsey cows and heifers, no entry. **Pigs.**—In Classes 72, 73, 74, and 75, for Berkshire pigs, Mr. H. Humphrey, Kingstone Farm, Shrivernham, takes first prize for the best boar; but Mr. Charlwood, Padworth, Berks, who takes second honours, is not far behind, both animals, however, being excellent specimens of this valuable breed. For sows Mr. N. Benjafield, Motcombe, Shaftesbury, Dorset, takes the first prize with a capital animal, Mr. Humphrey being second with a choice animal of this now profitable stock. The whole of these classes are worthy of the highest commendation. In Classes 76 and 77, for any large breed not being Berkshire, there were no entries; this is much to be regretted, for had the large white Yorkshire stock been exhibited it would have been seen that they are extremely valuable when killed for quarter pork, and also valuable for crossing with the Berkshires for general purposes, and especially for early maturity. Classes 78, 79, 80, and 81 represent small black pigs not being Berkshires.—Although these classes are highly meritorious, yet in these classes the Sussex and Essex breed prevailed, and these stocks are much esteemed in the southern and eastern counties. Classes 82, 83, 84, and 85, for small white pigs not being Berkshires.—The boars in these classes were very good, but we must demur to their being shown in very fat and perfectly helpless condition. The sows exhibited were capital stock, and we

were especially pleased with the sow and eleven pigs shown by Col. Portal, Ashe Park, Micheldever, Hants. In Class 85 Her Majesty again takes the prize with a pair of young sows, sent from the Prince Consort's Farm at Windsor, which were deservedly admired. The Sussex breed of pigs represented in classes 86 and 87 was a very poor competition, although this breed is kept more than any other in the South Hants district. The prizes were, however, taken by Mr. Kent of Bognor, Sussex.

We have entered at some length into the sheep, horses, cattle, and pig classes, each of them being very important to persons engaged in the management of home farms, and we trust that our observations and remarks will prove not only useful to young men commencing business, but that the names of the prizewinners will direct them where to obtain the best of all the kinds of stock they may require.

WORK ON THE HOME FARM.

Horse Labour now consists of preparing the land for turnips as fast as the green crops are cleared; but these will soon be finished, and we prefer drilling the turnips at once ploughing as fast as the land is ploughed in order to retain the moisture in the land, and when the turnips are drilled the same day as the land is ploughed the seed is sure to start into vegetation immediately. Sometimes, particularly in sandy or sandy loam soils, little bunches of couch grass will be found, which should be dug out with the prong as fast as the green crop is removed, but sometimes the labour is not available through haymaking and other urgent work; we do not, however, hesitate ploughing-in a few bunches of grass, because we always look over the turnip land before folding off the roots with sheep. In fact this is best and cheapest way to keep the land quite clean, and time can always be found for this work in the winter months; and the advantage is great, because an outlay of a few shillings per acre will save a pound in extra ploughing, besides the fact of the land being always ready when the season comes, without the delay caused by extra ploughing, &c. Horse-hoeing will still be required for the latest mangold crops and also for the Swedes, and in many cases where hand labour is scarce the implement invented for cutting out the plants into bunches in the lines may be used, but it can only be done where the plants are thick and regular in the rows. This, however, saves the plants from getting stunted, as the hand-singling and hand-hoeing may be done more leisurely afterwards; but we like the work of horse-hoeing across the lines quite as well as the implement for hoeing, as it moves the land better. The hand-hoeing and singling require great care in order that the plants may be left singly, and we have often remarked to our shepherd when he has been hoeing Swedes and other roots that we did not require any twins until lambing time. When vacancies occur in the root crops, and particularly in mangolds, we like to plant the large Drumhead Savoy cabbage plants, and always set them with the spade; they are then sure to grow if the weather is ever so dry and the land hard. The odd horse will still find plenty of work in various ways, such as carting and clearing away hedge clippings, carting clover for horses, cattle, and pigs. We like the system of feeding cattle in the stalls with clover in summer time, because in using the clover thus it may be cut three times instead of twice only for hay; there is no risk of spoiling like hay, and the result after feeding, as compared with that of hay as regards manure, is immensely in favour of foddering young growing cattle in this way, and we have never had nicer fat cattle at Christmas upon arable farms than where they have been fed in this way during the hot weather in summer, with a small allowance of cake, say 2 lbs. or 3 lbs. each per day.

The herdsman should now look to his heifers coming two years old, and turn out with them a young bull about fifteen months old; the calves will then come about the right time, that is in April and May, and this is the best time for heifers to bring their first calf, whether the breed is Shorthorns or otherwise.

Preparations should now be made for the harvest, and arrangements made with the men required, fixing the rate of wages, &c., otherwise when the time comes and casual labourers are the only ones to be obtained it will be found very uncertain as to how the work and the men's wages can be adjusted; also it is well to look to all the implements, carts, &c., required in the busy time of harvest, so that all may be in good condition for use at short notice. The cutting of winter oats, rye, and early peas will be begun in a few days, and it must be anticipated by getting all the work—such as hoeing of root crops, &c.—finished, in order that there may be no delay, as it will be indeed a busy time, because the second crops of clover will be ready at about the same time. The shepherds now will be drafting stock wether lambs for sale, some perhaps being required on the home farm, and care must be taken of the ewe lambs to have them dipped to kill ticks and prevent the attack of the blowfly; the ewes also will soon require to be treated in the same way where the wool grows up sufficiently.

We have received the schedule of a Poultry and Pigeon Show to be held at Winchester on August 14th and 15th, in connection with the Dog and Flower Shows. The poultry classes, twenty in number, are for chickens of the year, with three prizes in each of

respectively 30s., 15s., and 5s. Cockerels and pullets are shown separately. Pigeons have twelve classes, with three prizes in each, 15s., 10s., and 5s. Mr. W. B. Tegetmeier is to be the Judge. The rules against fraudulent practices seem to be stringent, and to be modelled on those of the Poultry Club. The name of Mr. T. C. Burnell is on the Committee, which is a guarantee that the regulations will be honestly and well carried out.

POLISH FOWLS.

THE increase of poultry shows has not done unmixed good to fancy poultry. The breeding of the most useful varieties, or those which from time to time are believed to be such, has been greatly stimulated by them, and the classes of these fashionable breeds are often immense; but the difficulty of making those for the rarer kinds pay, and the caprice with which old favourites are discarded for new ones, has brought down many ornamental—aye, and useful—kinds to the "any variety" class, where honours must necessarily much depend on the taste of individual judges. Many breeders unfortunately think too much of the results of these wheels of fortune, and so discard really valuable birds because they do not win. Such has to a great extent been the case with some beautiful varieties of Polish, now nearly extinct. We had not long ago at the Paris Exhibition the opportunity of seeing some of them, and, as we promised in our report of that Show, now proceed to give some further notes upon them. The varieties which there appeared over and above those which are well known were six.

1. Chamois.—There are no doubt some of these still in England. Within three or four years we have seen them at the Birmingham Show, but always of a dull mealy colour; not the bright yellow birds with white laces, such as they have in France. It was not that there were one or two good pens of these in Paris, but enough to make a class. The first-prize trio of hens and the first-prize cock were such as we had never before seen; the second-prize cock (which by the way has come to this side of the Channel) was even richer in colour, but a little spoilt by his close-fitting crest. The French judges seem really to have some definite idea as to the points which they desire in this breed, the chief of them being brightness and richness of colour, specially in the tuft hackles and tail of the cock.

2. Then came pure White.—We must say there were not enough of these. The characteristics of those there were did not strike us as being sufficiently defined to lead us to believe that the breed still exists in any great purity. We have vague recollections of some of this breed, which we then thought fine specimens, in a north country village some twenty years ago. It is true that in childhood we are apt to exaggerate the size of everything, still our belief is that there were large robust birds, pure white and bearded, in size more like Houdans than Polish, yet with real Polish heads. We have since seen a farmyard in Lombardy full of birds approaching this type yet showing signs of some cross from the smallness of their tufts and absence of beards; however, we had never before seen anything like good specimens in the show pen. There was in Paris one cock, deep in the moult and deeply tinged with yellow, yet evidently from his general expression a pure Polish fowl, which struck us much. Shown by the same exhibitor were four hens, matching in general form, but not so in legs. There were two or three more entries, but the birds were smaller and bore evident marks of relationship to Sultans.

3. Cuckoo.—These, we believe, are not so rare as the White, but less pure. Cuckoo is an easy colour to produce, and our British strains of Cuckoo Dorkings or Scotch-Greys have been spoilt by crosses. Some years ago a good pair of Cuckoo Polish were shown in England by the Rev. A. G. Brooke, but we have not seen any since in this country. There are a few at the Paris Jardin d'Acclimatation, and there were some at the Exhibition shown by an Italian Baron; these latter were good in colour, but small and poor in crest; they had combs, too, which looked as if they might be related to Houdans.

4. Ermine (French, *Hermine*) are certainly pretty. They are white birds with black spots on tail, hackle, and their well-developed crests. They are evidently a cross-breed between Silver-spangles, to which they are indebted for their fine crests, and White; indeed, the great Parisian dealer told us that he had so produced his exhibits.

5. Blue.—We have sometimes heard of Blue with white crests, but we never saw them. These were, however, entirely blue. They were shown by two Italian exhibitors, the hens being entered as Cremonese. Their appearance was spoilt by heavy fleshy-looking combs.

6. Frizzled.—We had never before seen Frizzled Polish, and thought both the Chamois and the White specimens good, for their size was large, their crests fine, and their colour pure. The French Judges were not taken with them, and considered them mongrels. We could not agree to this in the general acceptance of the term, for their uniformity of crests and thoroughly Polish look showed that the variety must have been long bred to a fixed standard.

We inquired about the long lost and now almost fabulous White

with black crests. We would fain add them to our list of the rarer Polish. We could get no tidings of the existence of any in France, or even of anyone who had ever seen them.

We heard much from French fanciers of an amateur in one of the central departments who devotes his attention greatly to Polish, and has fine specimens of every known variety. We have been promised an introduction to him, and hope on some future day to visit his yards and report upon them. Meanwhile we shall be very glad if these notes upon breeds which, though almost lost to us, yet do exist not far off, should induce any fancier to give them a trial.—C.

FATALITY IN YOUNG RABBITS.

EVERY doe Rabbit will breed half a dozen times, and have as many young at each litter; therefore a stock of three does and a buck may be multiplied in one year to over a thousand, because each young one will be able to breed when six or eight months old. Fortunes could be quickly reaped at Rabbit keeping if the increase continued at such a ratio, but unfortunately it does not, for many of the young are lost. These causes are not far to look for. The first plan seems to be to ascertain what kind of food the Rabbits like best, and then to force this upon them almost to their death, and certainly to the great detriment of their health. Young cabbage is often a great favourite with little Rabbits, but nothing is so bad for a constant supply of food. It is often given entirely, and many diseases result from it. When the young Rabbits are born they are apparently quite free from hair, but on looking carefully on the back a little silk hair can be discovered, which increases every day till the Rabbits are about a fortnight old, when a little wool grows. This increases for a week or two, and when they are about five weeks old they pass through a moult. This is a very dangerous time, and seems, like distemper in dogs, quite unavoidable and always to be expected. The best thing to do is to leave the young with the doe till the attack is over, and then to remove them into warm hutches. With the utmost care some will die, but the numbers may be greatly reduced by proper precautions. Extra attentions in warmth and food will not be thrown away and will be likely to save a few lives. As they attain a little over a month old a kind of looseness is very prevalent. The damp excrement sticks to the hocks and dries on, forming a hard scale, and frequently causes diseases of the hocks and feet. It has other bad effects: it gets on the skin and causes the hair to mat; then it can only be pulled off by causing pain to the Rabbit. The worst effect of the disease is that it is very weakening, and is as often caused by excessive heat as by improper food. Too much green or moist food will also cause the disease at any time. The only cure is to suddenly change the diet and give plenty of dry farinaceous food. The hutch should be cleaned out frequently, and a change to another hutch will be well.

Exercise is very good for the young Rabbits, and they should have it every day, the more the better if they enjoy it. The yard should be dry and inaccessible to cats. A grass plat well bounded affords a nice running ground for the young ones on a fine day, and they will nibble the short grass. If there has been much rain for some time the grass will be too damp. One of the results of a want of exercise is pot-belly, of which we have already spoken. Young Rabbits are particularly liable to it, and it is a very serious complaint. One sees it very much in Rabbits bred under young people's care, and the cause is the giving of too much green stuff. Exercise and judicious feeding are the only remedies that can be prescribed, and they act much better as preventives than as cures. A cure may be effected in a week or two if taken in hand at once before the skin is very tight, but if left for a fortnight or more before being taken in hand the effects may be very disastrous, and may quite destroy the young Rabbit's chance of life.

The skin of young Rabbits is very soft. In their gambols, especially at exercise, sometimes a nail will tear the flesh and make an open wound. The amount of harm caused by this will depend almost entirely upon the state of the Rabbit's health. If it is poor and ill the wound will fester if not taken in hand, but if the Rabbit is plump—not over-fat—it will generally heal, and the hair will grow over the place if not deep. In any case precautions may be taken, especially if the Rabbit is either very fat or lean. The wound should be washed out with warm water at once as soon as it is discovered, and the hair around carefully cut off with a pair of scissors. A little sweet oil may be applied if the wound looks very raw, or a little water bandage if there seems any chance of festering.

Above all adopt with young Rabbits a systematic course of treatment, and keep them warm, dry, and very clean.—GETA.

VARIETIES.

FROM an admirable paper on dairy farming read at the Midland Farmers' Club by Professor Sheldon we extract the following on the testing of milk: The quality of really pure milk being

found to vary so very much, and according to such a variety of causes, it will be seen how very difficult it is to determine with fairness whether or not it has been adulterated with water; but if it is found to contain over 10 per cent. of cream it may be reasonably set down as being of average quality. There are various methods of testing the quality of milk, but most of them have the serious disadvantage of requiring either considerable time or skill, or both these, in their determination. The test by analysis is the most exact, but this can only be done by a clever practical analyst, and it is necessarily a tedious and expensive process. The quickest test is made by the lactometer, but the fatal objection to this is that it is easy to cheat it. The cheating may be done by simply taking a portion of the cream from the milk and putting in some water in the place of it. Cream and water being each somewhat lighter than milk, it follows that the specific gravity of the milk is easily maintained by a substitution of water for cream. The simplest test is the common graduated glass cream gauge, but the objection against this test is that it takes at least twelve hours in demonstration, yet it is sufficiently accurate for all practical purposes. There is yet another method; I saw it tried at the International Dairy Show in Hamburg in the spring of last year. The milk is put into a glass tube similar to a cream gauge, and the tube is then corked up and placed securely in a socket in a wheel, which is afterwards caused to revolve at a great speed. The rapid revolution causes all the cream to collect at one end of the tube—the outer end—and the creamless milk at the other. It is a simple contrivance, speedy and satisfactory in action, the whole operation being completed in about ten minutes or less.

— DURING the trying period of moulting, says Mr. Flower in the *American Fanciers' Journal*, on no account should the cocks be permitted to run with the hens; the birds should be fed generously, and given a little of the Douglas mixture if moulting does not progress satisfactorily. The mixture is composed of half a pound of sulphate of iron to half an ounce of sulphuric acid dissolved in two quarts of soft rain water; dose one table-spoonful to a pint of water, placed in a vessel for the fowls to drink from at will. In lieu of this a few old rusty nails put into the drinking vessel will have a beneficial effect. Few if any fowls ever die from moulting, but in fowls where so much depends upon the colour and marking of the plumage as in this breed, it behoves the fancier to see to it that his stock are well cared for during this trying period of their existence.

— 109,000 quarters of foreign wheat recently came to the port of London in one week. As we have in the United Kingdom 23,903,314 acres of permanent pasture, and 6,459,404 acres of clovers, saintfoin, and grasses under cultivation, and as they are especially favoured this moist season, we need not be surprised at the fall in price of butter, milk, and cheese. Only 1s. per acre difference on this immense area represents a sum of £1,518,130, either in quantity or value. There must certainly be a considerable increase in the production of meat. Grass farmers have little to pay for horse or manual labour, seed, or machinery. —J. J. MECHI.

— It appears that a German colonist upon the island of Java has successfully tried the cultivation of the native bee, *Apis dorsata*, which hitherto has been valued by the natives only for the larvæ. Herr Mayerhöffer even expresses the hope that it will be possible to acclimatise the Javanese bee in Europe.

— On the evening of Sunday, July 14th, on the porter on duty at Ledsham station, on the Chester and Birkenhead Railway, going to light the lamp of the distance signal, a swarm of bees was found in the lamp. The swarm was hived and removed, and the lamp lighted in time to prevent danger to the trains.

— THE man, says Mr. G. W. Neihardt, that adorns his home with shrubs and flowers, raises delicious fruits for his table, and desires the education of his children in every useful art that agriculture and home affords, will succeed in keeping bees. On the other hand, the one who has not the interest or energy to do all these things need not expect to get either money or honey from bee-culture. Some of the requisites to care even for a few stocks of bees are first a love for the bees. No one succeeds well who keeps bees with only large profits in view, for in this business "he who maketh haste to be rich" will surely fall into a snare. Second, knowledge and energy to do the right thing at the right time. This can be attained by reading and observation, and time and money thus expended will prove a good investment. Third, faith that bees will pay if rightly kept. A like faith is necessary in this vocation as that which the farmer exercises in all his farm matters.

— YOUNG chickens and ducklings will obtain a large part of their living from insects, if they have the opportunity. It is a good plan to give up a part of the orchard to poultry. Chickens and ducks want shade as well as sunshine, and thrive better for it during the summer. They are always on the watch for worms and millers, and greedily devour every insect that falls from the trees. They are fond of fruit, and consume the windfalls, which harbour the insects that are so destructive to fruit. A brood of

chickens left under an apple tree affected with cankerworms or caterpillars, will reduce the stock and finally exterminate them. One of the most successful fruit-growers we are acquainted with keeps poultry constantly under his trees. The apples and pears are fair, and he has paying crops every year.—(*American Agriculturist*.)

STILTON CHEESE acquired its name from Stilton in Huntingdonshire, where it was first publicly sold; but it is said to have been first made at Wymondham, near Melton Mowbray. At the Bell Inn, Stilton, it obtained such celebrity as to be sold by the landlord at 2s. 6d. a pound, and was called the English Parmesan. The process of making it was long kept as a secret. To the morning's new milk add the skimmed cream of the preceding evening's milking, with a proper quantity of rennet. When the curd has come it should not be broken in the usual way, but should be taken off carefully, and placed in a sieve to drain gradually. As it drains, gently press the cheese till it becomes firm and dry, and when taken from the vat keep it till quite firm, and repeatedly brush it. Great care is required to keep the cheese sweet and good till fit for use; the time of keeping till quite ripe is from twelve to eighteen months. In order to eat a Stilton cheese in perfection you must not only have one made of rich milk, but manage it well after it is made. To hasten the growth of green mould, several pieces of mouldy or over-ripe cheese are inserted into holes made for the purpose by a taster; wine or ale is then poured in. But the best Stiltons do not require this, for they are in perfection when the inside is soft and rich, like butter, without any appearance of mouldiness. In France, when a Stilton has become very dry, dealers wash it several times in soft water, and then lay it in a cloth moistened with wine or vinegar till it becomes soft and mellow, which it will inevitably do if it be a rich cheese. This simple method is generally practised in Switzerland, where cheeses are kept stored for many years, and if they were not salt and dry they would soon be the prey of worms and mites. It is then put into a shape in the form of a cylinder, 8 or 9 inches in diameter. When it is sufficiently firm a cloth or tape is wound round it to prevent its breaking, and it is set on a shelf. It is occasionally powdered with flour, and plunged in hot water; this hardens the outer coat, and favours the internal fermentation, which ripens it.—(*Cassell's Household Guide*.)

HONEY PROSPECTS.

THE last paragraph of Mr. Pettigrew's letter, July 11th, is most encouraging, and will, I hope, be verified in many parts of Great Britain. Here in West Norfolk we have hitherto had a season of swarming rather than honey-gathering, though there was much of both at the beginning of June. The latter half of the month was on the whole unfavourable. With the "good time coming" which Mr. Pettigrew promises us the much-needed addition to our stocks may be of great service next year, and there may even be a fair amount of run honey. But it is now too late to expect much from supers, and those that do get filled will not command high prices.

I have this year taken two supers full but imperfectly sealed, and have two fine ones not quite ready; whereas last year, much abused as it was, I had taken several full and well sealed a fortnight earlier. Perhaps some of your correspondents who go in for early supers will tell us how this year suits them.—E. H. R.

P.S.—Has anyone observed the rich colour of the early comb this year? As a rule the first combs in hive or super are of a delicate straw colour, which deepens as the summer advances. This year my late combs are the paler of the two.

OUR LETTER BOX.

BLACK DORKINGS (J. S. T.).—We have often heard of jet black Dorkings, but have never seen them. Some of the largest and best birds of the breed were very dark, and appeared black when hatched. Such were the birds shown for some years by Lord Berwick. No speckle or spangle on the plumage, but a very dark, almost black, feather, relieved by a white shaft. Such generally had brown breasts. The cocks showed brown, and sometimes white feathers, especially in the tail. There are frequently many changes to take place after chickens are eight weeks old, and we have little hesitation in saying that if they are black-feathered now they will not remain so. A black Dorking is an impossibility. It is the only inadmissible colour. Our advice to you is to buy the cocks, to put them with your own, and to choose for size and symmetry, shutting your eyes to feather. We have often seen these dark cocks birds of great size, and many of those that gained renown for Admiral Hornby were very dark.

CHICKEN FASTING (F. C.).—Fourteen days is a long period for a three-months-old chicken to have been without food; but we heard of a hen that was rather longer fasting, yet survived and lived for a year after.

HIVES WITH OLD COMBS (Triceps).—As the combs of your hives which have not swarmed are old and discoloured we advise you to drive the bees out of them into two empty hives and take their honey. If the weather became unfavourable for honey-gathering let the bees in the empty hives be well fed, and they will become far better stocks for keeping than the old ones. Let the bees be driven on an evening about seven o'clock; the process is simple and easy.

TIERS OF SUPERS (F. J.).—Theoretically you are right in fancying that in placing a tier of supers on a hive the empty one should be next the hive

or nearest home. Bees naturally store honey at the utmost and outermost points of their combs, and fill-up towards the centre. Thus, naturally, the finished supers should be above those that are in process of being filled and not travelled over by bees carrying honey to empty ones above them. Mr. Fox's supers about 100 lbs. each were filled on his adjusting principle—that is, by raising the super stage by stage, and thus keeping the bees at work near the crowns of their hives. Mr. Fox said he did not think his large supers could have been filled on any other principle. Your idea of placing the empty supers beneath the full ones is quite in harmony with the laws of Nature and the opinions and practice of Mr. Fox. But those who have managed the Stewarton hives for years approve of the empty supers being placed uppermost, and it appears they practise this mode of action, and as they are honest practical apianians we are bound to respect their opinions. Though they have not given us good reasons, or, perhaps, any reasons at all for placing the empty supers above the full ones, doubtless they are able to do so. We should be thankful if our friends will give us their reasons for choosing the course they pursue. The subject is important and should be well ventilated and understood. At present we are in favour of full supers being removed from their hives as fast as they are filled and finished.

FOREIGN INSECTS (T. Dorset).—The insects forwarded are of the species commonly known as *Anthrenus Muscorum*, beetles belonging to the family Ptinidae, in which are included several species only too destructive to specimens preserved in cabinets. The fact that the case appeared to be securely closed-up would be no obstacle to the parent beetles; the eggs being laid in some tiny crack in the wood, the young larvae would gradually work their way in. In such a case the insects must be removed from the infected case and exposed to the vapour of benzoline, or they might be placed for a short time in an oven or placed in a new receptacle.

REMARKS.

- 10th.—Fair but overcast; dull cloudy evening. [evening.]
 11th.—Dull but pleasant morning, sunny and bright after 4 P.M.; very fine
 12th.—Fair day but very cloudy, and almost sunless; very slight rain in evening; dark night.
 13th.—Very bright sunny morning, cloudy dull afternoon; fine sunset.
 14th.—Fine throughout; very bright early, but afterwards overcast and close; slightly misty in evening. [fine afternoon and evening.]
 15th.—Another fine day, overcast and stormy-looking from 0 to 1 P.M.; very
 16th.—Bright, sunny, and warm day.
 A very fine week, but without extreme heat. No measurable rain.—G. J. SYMONS.

COVENT GARDEN MARKET.—JULY 17.

ALL kinds of soft fruit are now well in, and with fair crops are making good prices. The London season being nearly over, there has been a great decline in the value of Grapes, Peaches and Nectarines maintaining their prices. Pines are a good sale.

From observations taken near London during forty-three years, the average day temperature of the week is 74.9°; and its night temperature 54.1°.

JUDGING AT EXHIBITIONS.

FROM time to time the advantages of the system of judging and awarding the prizes at the great London horticultural exhibitions have been pointed out, and the corresponding disadvantages of the modes adopted at some local shows have been incidentally alluded to.

The two systems in operation may be broadly described as open judging and blindfold judging. The one is founded on the principle of trusting to the honour of judges, the other is dictated by the petty and paltry jealousies of local exhibitors. In theory there can be no question as to which of the two principles is the better; and in practice, at least in regard to great shows of a general character, the principle based on a virtue instead of the one founded on something of a very different character, gives by far the greater amount of general satisfaction. The one mode is circumlocutory, cumbersome, slow in being carried out, and not infrequently results in inaccuracies; the other is simple in its nature, essentially expeditious in its operation, is seldom attended by mistakes, and scarcely ever gives cause for complaint by any who are in any way connected with the exhibition.

Never, perhaps, were the faults of the blindfold system of judging more apparent than at the great Show at Preston. The manner in which the prizes were affixed and the general administration of this department of the Exhibition constituted the greatest blot of the Show. The way in which the officials were worked and the general muddle in which they were involved evoked the sympathies of those to whom the work would have been easy had it been conducted on the usual system adopted by the Royal Horticultural Society. When the Society holds its next provincial Exhibition it is earnestly to be hoped that the duties in the department alluded to will be administered by the Society's officials, and that the common-sense system usually in operation will not be departed from in favour of one dictated by local fancies, prejudices, or jealousies, and which is altogether inferior.

The system adopted at Preston was rude in comparison with the plan that it was permitted to supplant. It may be well to contrast the two systems and their working.

At the London shows, as noticed by "EXHIBITOR" on page 50, every exhibitor's name and full address is plainly written on a card, on which is also printed the class, number, and designation of the exhibit. These cards are placed on the several collections before the judges commence their duties, the cards being simply turned face downwards, and on the back of each is written the class and exhibitor's numbers, which are all the judges care to see or do see. The awards are made to the numbers, and an official in attendance on each set of judges is provided with a supply of boldly-printed "first prize," "second prize," "third prize," and "extra prize" slips ("highly commended" and "commended" slips being also in readiness if required), which he places on the successful exhibits, at the same time turning the cards, and the work is done. There can

be no delay nor error where this plan is adopted. The judging and affixing of the prize cards are done simultaneously, the reporters can discharge their duties correctly and expeditiously—which is not of less importance to the general public than to the Society—and all is in readiness for the visitors, who can see just what they desire to see the moment they enter the show.

That is the open, judge-trusting, common-sense system of procedure which works so smoothly and so well at all London exhibitions of the Royal Horticultural Society, the Royal Botanic Society, the plant and fruit shows of the Crystal Palace Company, the shows of the National Rose Society, the National Pelargonium Society, the National Auricula Society, the National Carnation and Picotee Society, and at many suburban exhibitions. London exhibitors and critics are as keen as most people, but a complaint is practically unheard of in connection with the awards at the shows referred to.

The blindfold system as adopted at Preston was worked as follows:—Exhibitors' numbers and class numbers were alone placed on the cards before the Judges. The awards were made and attendants conveyed the slips to the office. The names of the successful exhibitors were then searched for, three or four officials clustering round one book, and then having to refer to other books for gardeners' names, addresses, &c. The names were then written on the prize cards. Another body of assistants then conveyed the cards back to the Show, and after some trouble—often considerable in finding their places—affixed them to the exhibits. But after all the time occupied and all the labour expended no addresses were written on the cards, and not always the name of the gardener; while in other instances the name of the gardener was given with the honour of "Esq." attached, the name of the owner of the collections being omitted. Yet with all these imperfections three hours or more elapsed before all the awards were affixed; whereas by the London system the work is done in two minutes. The faults alluded to—for faults they are—pertain wholly to the system and not to the officials who carried it out. No body of men could have worked harder than did those engaged in this department at Preston, and if they had been under a less cool head than that of Mr Moore the work would not have been executed so well as it was.

The object, it is presumed, of blindfold judging is to remove any cause of mistrust that might arise lest the judges should favour any particular exhibitor. It is simply absurd to suppose that any judges having a reputation at stake would do other than judge justly; but even if they were disposed to act otherwise, the numbering system would not only not prevent their doing so but would assist them; and for this reason, that they know by the plants, &c., whose collections they are judging, so that in point of fact the numbering system is all a farce. When the exhibitors' names are placed with the collections, although the judges do not see them, nor want to see them, that is the best possible security that can be devised that everything will be judged strictly on its merits. If the judges did otherwise they would simply have no defence; but if they

judged under number the very numbers would afford them valuable shelter. Let the judges be trusted, as they ought to be, and the same satisfaction will be given at the large country shows that is such a striking and pleasant feature of the London exhibitions.

ROSE SHOWING.

As Mr. Hinton says, ever since the Rose election, articles have been appearing in the Journal discussing the various points of an exhibition Rose; and the one point upon which nearly all the writers seem to agree is that a medium-sized Rose having good form, colour, freshness, &c., should rank above a larger Rose lacking either of these points. An instance is mentioned by one writer of a gentleman setting up a stand of undersized Roses in a small box, so that they were brought close together, and were consequently awarded the prize, being referred to as a nice even lot; while another stand containing some larger blooms was compared to a lot of Cochins' and bantams' eggs mixed up together. But it would seem as if the Judges at Hereford (I have not the least idea who they were) were of a different opinion. This makes it more desirable that the suggestion of printing the names of the judges on the schedules should be carried out.

In "WYLD SAVAGE'S" glowing word-picture of the above Show (and what a masterly hand he is at this work!) there are four points of excellence mentioned about Mr. Jowitt's stand of thirty-six, and three faults about Mr. Baker's—viz., "Mr. Jowitt's was more even, had more Teas, were more varied in colour, and the arrangement was a little better; Mr. Baker spoilt his box by inserting in the back row a large coarse bloom; his Capitaine Christy was a little past, and three Roses were a little undersized;" and yet he was awarded the first place! This seems like the reverse of the case referred to above.

In closing, let me say I am not an acquaintance of Mr. Jowitt's disappointed at his defeat. I never to my knowledge saw him, neither do I know Mr. Baker. I simply write in the hope that the cognoscenti will write further upon the subject of Rose showing and judging, and so the smaller fry will gain information, and perhaps some may fall to the lot of—A LOVER OF ROSE SHOWS.

P.S.—What about the rules for judging decided upon by the National Rose Society? [They are published in another column.—EDS.]

SEASONABLE NOTES ON FRUIT TREES.

SHOULD the present fine weather which we have experienced for the last two or three weeks last much longer, we shall hear no complaints next year of fruit trees bearing badly through the wood not having been well ripened. No doubt this is often one of the causes of a deficient fruit crop, and it is also very often the cause of fruit trees losing their branches and fine healthy-looking limbs dying-off at all times of the year without any apparent cause. But allow me to state that when this takes place I think it is frequently as much the fault of the cultivator as the absence of sun or any other cause. If we may judge other people's trees from our own they will have made a great quantity of wood during the early wet part of this season, and to allow early spring and summer growths of this kind to "hang as they grow" until the end of the season, or until they are pruned and nailed again, as is very often the case, no amount of sun will have fruitfully matured the wood, simply because in masses of young wood the sun only scorches a few of the leaves on the face and never penetrates to the base of the shoots, which is the chief fruit repository of another year.

It is some weeks since we went over all our trees, and they are now being gone over again. On the wall trees all the shoots which have grown straight out were cut-in to 2 or 3 inches from where they started, and where there was room to extend the branches the points were left untouched. The standards were treated in much the same way, only some of the leading shoots were cut at 8 or 10 inches from the base, and the others from 2 to 3 inches. Before doing this it was quite impossible to see the main stems of many of the trees, and to leave such a quantity of wood with the intention of its ripening was quite out of the question; but after the shoots had been shortened the sun and air penetrated freely to every part of the wood, and whatever our crops fail for next year, it will not be for the absence of hard wood and plump eyes or

buds. The work at the second pruning is light, as it is only a twig of a second growth here and there that has to be taken off, and the leading points which were left last time tied-in. Many will say they have no time to go over their trees in this manner, and I know it is the case in many gardens where there is only one man to do the work of three; but even in cases where this false economy is carried out, I strongly advise that whatever else is neglected try to find time just now to cut-in the wood of your fruit trees. Do not leave it until winter when there is more time, as then all the good influences of the summer, and especially of the sun, will be lost.

Pears, Plums, Apples, and Apricots may always be "spurred" in; but Peaches and Cherries, especially Morellos, should have the strongest shoots tied in and all the weakly or superfluous growths cut away. It is this that insures the thorough ripening of the fruit-bearing wood, as well as balancing the growth of the tree and doing that justice to it which every tree deserves that is expected to produce a fair supply of fruit. The more wood there is on the tree the greater is the demand for attention, and the more shaded the situation may be the greater the necessity of exposing the permanent growth. Apart from the advantage the trees derive from work of this sort now it is a gain in other ways; as where cutting off the shoots is done carefully now little or no winter pruning is required, and the wounds at the points of the spurs are healed over without being exposed to severe weather in winter.

We do not nail-in the shoots of our Peach trees at the present time, but the points of the shoots are cut from the Currant bushes, the leaves stripped off, and the shoots pressed back with them, each end being fixed behind some of the old nailed-in branches. This holds them very well until the trees are overhauled in winter, and at the same time it opens up the Currant bushes by using their young shoots. When time will allow, Gooseberries, Raspberries, and all kinds of small bushes are benefited by having their wood thinned at the present time.—A KITCHEN GARDENER.

BUILDING A GREENHOUSE.

IN the construction of a greenhouse, he who best combines strength, lightness, and soundness is most successful, for these are the fundamental points of most importance. Add to them a good method of ventilation, of staging, of affording artificial heat when necessary, use good materials, let the workmanship be honest, strong, and true, and you will have all that is essential in your building and nothing that is superfluous. Ornamental ridging, porticos, ironwork, may of course be added *ad libitum* according to individual fancy, but they are unnecessary, and need not, therefore, be taken into account in a paper devoted solely to matters of practical importance.

A correspondent asks for assistance about the details of a span-roofed greenhouse about 20 feet wide, and I have made a few sectional drawings calculated to set the matter clearly before him and the numerous readers of the Journal to whom such hints are likely to prove useful. Fig. A represents a transverse section of a plain serviceable structure, drawn to a scale of one-fifth of an inch to a foot. The points of importance, and to which attention must be given, are:—

The Roof.—This is only 5 feet high at the eaves and 10 feet at the apex. It consists simply of fixed rafters morticed into a ridge-board at top and an eave-board at bottom. The width of the ridge-board (fig. B) depends upon that of the sashbars. Two inches will be thick enough for the house we are treating of. Fig. C represents a section of the beading fastened by screws or nails to the top of the ridge-board, as in fig. D, to preserve it from the action of the weather as well as to impart finish to the building. Fig. D also shows how the sashbars are morticed into the ridge-board, 1, 1, and how a groove, 2, 2, for the glass is ploughed in the ridge-board above each tenon. In glazing especial care must be taken to thrust the glass to the top of these grooves, so as to make the ridge weather-proof. The size of the sashbars is determined by their length and whether it is intended to strengthen the roof with stays or pillars with such excellent supports as shown in fig. A. A bar of the form shown in fig. E, $2\frac{1}{2}$ inches by $\frac{1}{2}$ at its widest part, answers very well, with every fifth bar like the section fig. F, in size $3\frac{1}{2}$ inches by 2. When interior supports are not used the bars should be 3 inches by $1\frac{1}{4}$, with every eighth bar $3\frac{1}{2}$ inches by 3. I have given all these bars a thorough trial and can recommend them. The eave-board (fig. G) should be 4 inches by 2, bevelled as shown, and with the small semicircular groove 1 to prevent any moisture creeping into the house under

the eaves, as will happen without the groove. In exposed windy situations additional strength may readily be imparted by bolting a few iron braces to the angles of the building at any convenient point, as in fig. H. Pieces of bar iron bent to the required angle, flattened, and holes pierced at the ends by a blacksmith, answer admirably, and are neat enough in appearance when painted.

The roof support which I have designed for this house, though somewhat novel, is, I think, preferable to the ordinary method. It consists of central pillars with two arms springing through the central tier of the stage at about 9 feet apart. The hanging baskets, 1, 1, have a counterpoise at the end of a chain or cord running over a wheel, so as to be raised or lowered at will for convenience in watering and inspection of

Fig. 9.—PLAN OF GREENHOUSE.

the plants. The effect of two such rows of baskets when well filled would be pleasing and materially enhance the appearance of the interior. To those who prefer the usual plan of side pillars fig. I will be useful, as showing a longitudinal sectional portion of such a pillar, with a slot cast in the top to admit a flat iron bar on edge, 1, running along under the roof from end to end, and forming a capital support, so slight as to make no appreciable shade, and yet very strong; in size it is 3 inches by half an inch. The brackets for hanging shelves in fig. A, 2, 2, are objectionable as spoiling the appearance of the interior, but such shelves are so useful that I have shown where they should be placed for the guidance of those who are compelled to use them.

The Sides.—Here the sashbars are similar to those in the roof, the only difference being in the large size, which, as they help to support the roof, are 3 inches by 3. They are morticed into the wall plate J, which is about 6 inches by 2½ or 3, as may prove most suitable, and into an eave plate K, 4 inches by 2½. The angle pieces for the corners of the building, L, are 4½ inches by 3, and have rebates, 1, 1, for glazing and for ventilators to shut into. When side ventilators are introduced, 3, 3, fig. A, they consist simply of a frame 2½ inches by 1½, grooved for the glass, with sashbars morticed into the frame, and are suspended by hinges to a fixed bar 2½ inches by 1½, into the upper side of which the top side fixed sashbars are morticed. Although mention is made of side ventilators, it is by no means

intended to imply that they are an indispensable necessity, for if the roof ventilation be but thorough, side ventilation is not wanted, and fixed sides point of course to a considerable saving. Let, therefore, the roof ventilators run from end to end of the roof, and consist of a clear space of quite 2 feet in width, so as to admit such a large volume of air as to insure a brisk and thorough circulation. Avoid a cheap opening apparatus, let it be strong, and yet so easy that a touch may set it in motion. The best principle is that of a spiral shaft and stout-jointed levers by which the ventilators may be regulated to a nicety. The brickwork of the sides and ends consists of five courses above ground and six courses below, inclusive of the footings. The walls are 9 inches thick, and the footings are respectively 13½, 18, and, 22½ inches, so that a yard in length of wall and footings will require 112 bricks, and to make enough mortar for five hundred bricks it requires three bushels of new grey lime and eighteen bushels of sand.

The doors should be 1½ inch in thickness, and the doorposts 4 inches by 3, with rebates and beading as in fig. M; rebate 1 in for door and 2 for glass. The central stage has upright supports 2 inches by 2 (see 4, fig. A), and the braces (see 5, fig. A) are 3 inches by 2. The strips forming the shelves are 2 inches by 1, with half-inch spaces between every two strips. The woodwork of the side stages is of the same size.

The glass for the roof to be 21-oz. seconds; size of squares, 20 inches by 12; and for the sides and ends 16-oz. answers very well. The hot-water pipes to be 4-inch and slightly elevated above the floor on pipe stands as shown. The scale is only for fig. A.—EDWARD LUCKHURST.

NOVELTIES IN THE ROYAL GARDENS, KEW.

ANTHURIUM BAKERI, a new species, is bearing splendid fruit in the house No. 1. It is always pleasing to note the adaptation of a novelty to some special purpose; and this, unlike any other species we remember, has decidedly ornamental and persistent fruit, and appears suitable for showing in a loose arrangement of cut flowers. To such, an addition of this kind is both in good taste and generally attractive. The berries are scarlet and grow very densely on a spike 4 inches long; its spathe is small and green without any beauty. In habit this plant is similar to *A. Schertzerianum*, but is quite distinct in its long, narrow, coriaceous leaves. It was introduced from Costa Rica.

In the herbaceous department *Fritillaria Hookeri*, an important and quite recent introduction, has just flowered. It is so intermediate in character as to be classed with almost equal propriety among the Lilies, and this with its unusual colour, a pale lilac, makes it a most interesting plant. Its nearest ally, *F. macrophylla*, is perhaps best known as *Lilium Thomsonianum*, but we follow Mr. Baker, who has devoted the most critical study to this as well as to most other groups of *Monocotyledons*. The peculiarity of its colour is immediately noticed, and also that there is no tessellation, then, that the bracts form but one series with the leaves. The lowest flower is subtended by a leaf of considerable size, and the highest by a small bract. It grows about a foot high, and bears five or six flowers an inch long. Sir Joseph Hooker discovered this *Fritillaria* in the temperate region of the Sikkim Himalaya, where it grows at a height of 9000 to 10,000 feet, and to Mr. Elwes is due the credit of its introduction. *Primula capitata* is a rarity of great merit on the rockwork. It has a dense head of remarkably deep blue-purple flowers, and the scape is covered with a dense white meal, making it still more attractive. It was introduced some years ago, but we believe had been lost till recently. The new *Delphinium Cashmerianum* is also in flower; it has blue flowers and very dwarf habit, which makes it suitable for positions to which most other species are not adapted. On the strip of rockwork devoted to the order in the herbaceous ground we find *Sedum sempervivoides*, a rare species not unlike *Sempervivum* in foliage, but when it flowers is strikingly like a small scarlet-flowered *Rochaea*. *Umbilicus Sempervivum*, now past its best, is also worthy of note; it has a pretty rosette of broad leaves and with a large number of pale pink flowers. *Antholyza angusta* and *A. Meriana* var. *Ludwigii* are Irids of great merit for the open ground, appearing as they do to be hardy. The first is scarlet and the latter inclines towards salmon. Both are of similar shape, having long tubular flowers with spreading limb.

Haemodorum aurantiacum is quite a picture in the house No. 4, and we venture to draw attention to it, since, though not new, it is still uncommon and known to few. The panicles

are a foot long and composed of numberless bright yellow flowers. It is planted out, and in that way, like its relative *H. elegans*, appears to do much the best. *Berberidopsis coralina*, perhaps the most ornamental of climbing *Berberids*, is now profusely bearing its globular deep red flowers.

Trapa natans is flowering and fruiting freely in the Victoria tank. It is known usually as the Water Chestnut—sometimes, however, as Water Caltrops, from its resemblance to an instrument of ancient warfare used to impede the progress of cavalry by strewing it on the ground. It has considerable interest and value, the first on account of its peculiar fruit, the horns of which, it is interesting to observe, are the enlarged persistent sepals. Here the transition is clearly seen. In the south of Europe, where very abundant, the farinaceous part is made into bread and also is eaten raw extensively; it is said to have formed a considerable part of the food of the ancient Thracians. It has been suggested that it would be a valuable introduction to this country and might be naturalised. The possibility of its becoming so is more than doubtful, since it rarely flowers under cultivation out of doors, and still more rarely fruits. In the Victoria tank, too, it seems to enjoy the temperature of 85° Fahr., and is quite at home. The floating triangular-toothed leaves form elegant radiant clusters, and the petioles have a spindle-shaped swelling analogous to that of *Pontederia crassipes*.

In the Palm house may be noted an *Acanthad*, evidently useful and ornamental, but still unknown, we believe, out of Kew. This is *Beleperone plumbaginifolia*, a native of Brazil. Its branches freely into many slender stems, which arch in a graceful manner. The leaves are ovate-lanceolate, 2 or 3 inches long, each in its axil bearing a cluster of flowers in shape and colour much like those of the old favourite *Justicia carnea*, but slightly reduced in size. In the Lily house *Batatas paniculatus*, a splendid climber with lilac flowers, similar in shape to those of *Ipomœa Horsfalliæ*, but still larger, is growing round the rails of the tank at a fast rate, and bids fair to form for it a floral wreath.

Among choice ornamental shrubs we notice several to be very fine at Kew. *Rosa moschata* has free growth, suitable for rambling over rocks or roots, and the profusion of single white flowers makes it highly attractive. Among the *Ligustrums* we know of none more graceful than *L. sinense*; it has light-looking foliage, and the panicles of white flowers have had a fine effect in several shrubberies. *Spiræa Nobileana* is in fine condition, and the less known *S. arisæfolia* will shortly have an appearance almost equal to masses of *Hoteia*.

Scolymus maculatus, a Thistle-like plant with many stems of brilliant yellow flowers, is now the most showy of herbaceous plants at Kew. It grows about 3 feet high, and for the wild garden is a splendid plant. *Salvias* are interesting to many, and a species we have not before seen is *S. farinacea*; it grows erect, bearing pretty ovate smooth leaves, with spikes of delicate blue flowers, each with a white spot on lower lip. *Veronica devoniensis* forms a neat-growing dense shrub; the leaves are small, and the racemes of white flowers are numberless. *Phlomis fruticosa*, the Jerusalem Sage, is an old favourite well known to many, and one of the most quaint plants for select shrubberies.

WOLVERHAMPTON HORTICULTURAL SHOW.

THIS was in every respect a good one, and showed a marked improvement on the last held. Some of the best exhibits came from very unpromising localities, being uncomfortably near to the Black Country, and consequently reflected greater credit on the exhibitor for the extra care and attention necessarily bestowed on them; in fact being a good instance of what competition will encourage men to do under difficulties. The best collection of plants was staged by Mr. Taylor, gardener to J. Evans, Esq., who was also first in the classes for stove and greenhouse plants, fine-foliaged plants, a collection of fruit, Pines, Peaches, and Tomatoes. Mr. Bucknell, gardener to H. Lovatt, Esq., was first in the classes for a single specimen foliage plant, *Achimenes*, and *Cockscombs*. Mr. Edwards, gardener to E. F. Smith, Esq., was first for Black and White Grapes, Cucumbers, Calceolarias, and a single plant in bloom. Mr. Coleman, gardener to W. Bayliss, Esq., was first for British Ferns, *Gloxinias*, and *Caladiums*. Mr. Crowe, gardener to Staveland Hill, Esq., M.P., was first for Zonal Pelargoniums, Potatoes, &c. Mr. Witts, gardener to D. North, Esq., was first for Exotic Ferns and the heaviest bunch of Grapes; and Mr. Dean, gardener to R. Kittle, Esq., for Pelargoniums, a collection of plants, Balsams, &c. The competition in the *Fuchsia* classes was very spirited, the first prize being well won by Mr. Collins, gardener to E. F. Gough, Esq., who was also successful in other

classes. There was an extraordinary competition in the class for a pot of Musk, Mr. Perry, an amateur, winning with a plant fully a yard high. The Show remained open for two days and was well attended.

STANDARD ROSES AT RATHRONAN MANOR, CLONMEL.

ANXIOUS to see a superior stock of standards well grown in Ireland, and to inquire into the mode of procedure, I visited the beautifully situated country residence of "Judge" Gough as he is popularly called here, and was shown over the gardens and grounds by Mr. Mulcahy, by whom they are managed. We were struck at the entrance by the tall colonnade of stately Beeches, and with their gently undulating grassy slopes on each side of the avenue. The lawn was studded here and there with old majestic-looking forest trees that must have braved many a storm and seen years of time and change. After a look through a carefully cultivated vegetable and fruit garden, well-stocked viney (the Grapes being a heavy crop), and one of the most neat and tasty greenhouses it has been our lot to see, we come to the pleasure ground and flower garden terraced immediately in front of the mansion. This space is divided into two squares, and along the margin of these we found the immediate object of our visit, a profuse bloom of healthy and well-grown standard Roses—a splendid contrast with the carpet bedding and subtropical gardening. Four beds of Tuberous Begonias particularly were also very striking.

There are peculiar circumstances where the Rose must be cultivated as a climber, as on walls, trellises, or pillars—cases, and too rare, where it should be employed as a bedder. None can compare, however, in my opinion to the standard shape and habit of growth. As there are always beginners in Rose culture, and as the present is the season for budding, a few notes thereon may be seasonable.

Attempts are sometimes made to bud on the Briar where found growing, with the view of transferring when established; but such experiments are generally not repeated. A better plan is to collect a sufficient number of clean, healthy, and sufficiently advanced Briars in the autumn, and transplant them in lines in a cool and rich border of the vegetable garden, trimming the roots and heads with judgment. There they grow luxuriantly, and the superfluous buds are rubbed off, leaving only shoots on which you intend to operate. In July they are growing vigorously, and as soon as buds are sufficiently advanced they should be inserted. If you have them not, no gentleman or gardener will refuse them to you. Success in budding very much depends on the state of the weather, dull damp weather conducing much to success; but it should ever be borne in mind that your main object is to insert the bud on the stock as it was growing on the parent stem, and to take every precaution that it receives few checks. Anything that induces reciprocity of sap-circulation between stock and bud, as damp moss, a Cabbage leaf, &c., in parching weather will materially conduce to success. Rather than attempt describing the process of budding, I say to beginners, Go and insert half a dozen buds under the direction of an expert, and you will, after understanding the object in view, be ever after able to do it for yourself.

At Rathronan, the soil being of a loamy nature, the Dog Rose answered admirably as a stock. In adjoining localities Roses only succeed well on the Manetti. For instance, at Minella Gloire de Dijon, John Hopper, Jules Margottin, François Arago, and many others were found only to succeed well on the Manetti stock by the intelligent head gardener there. As to soil, nothing is better than a good old loam with a suitable admixture of old decayed manure. The typical manure is one or two years-old hotbed, well decomposed. Thus prepared as here, the new Roses are removed as required from their lines in the vegetable garden border; and with due attention to pruning and disbudding for some time until the requisite form and shape are attained success will in nine cases out of ten reward your exertions.

The following are the principal Roses that flourish well as standards in this part of Ireland—

Hybrid Perpetuals.—Beauty of Waltham, rosy carmine; Charles Lefebvre, velvety crimson; Eugène Appert, dark crimson; John Hopper, rosy crimson; Jules Margottin, cherry; Baron Rothschild, carmine; Madame Victor Verdier, vermillion; Madame Rivers, flesh; Sénateur Vaisse, scarlet; Victor Verdier, cherry rose; Miss Ingram, white, with centre flesh. The foregoing are old-established favourites, and the following are very superior kinds more recently introduced—Etienne Levet,

almost thornless, carmine red; Ferdinand de Lesseps, purple; Edouard Morren, glossy pink; Alfred Colomb, fiery red; Abel Grand, silvery hue; Capitaine Christy, flesh, shaded to rose in centre; Boule de Neige, small flowers, pure white; Docteur Andry, brilliant red, imbricated; Duke of Edinburgh, fine vermillion; La France, lilac rose; Madame Marie Cointet, bright rose; Madame Lacharme, a fine white; François Michelon, deep red, seedling probably of La Reine; Centifolia Rosea, clear rose, very fragrant.

Noisette.—Céline Forestier. *Bourbon*.—Baronne de Boumont, light rose; Narcisse, primrose yellow; Triomphe de Rennes, canary yellow. Maréchal Niel and Gloire de Dijon and other climbing, pillar, and Moss Roses are well represented at Rathronan.—W. J. M., *Clonmel*.

ROYAL HORTICULTURAL SOCIETY.

JULY 23RD.

THE tables surrounding the Council-room were quite filled with plants, cut flowers, and fruit, some exhibiting superior cultivation, and others being new and submitted for certificates. There was also a good attendance of horticulturists, and the meeting on the whole was a successful one.

FRUIT COMMITTEE.—Henry Webb, Esq., V.P., in the chair. Mr. Clark, The Gardens, Melton Constable, East Dereham, sent five varieties of Melons, two of which were seedlings, named respectively Melton Gem and Melton Favourite, neither of which was of great merit, but a letter of thanks was awarded for the collection. Mr. W. Wynne, The Gardens, Worthorpe Road, Stamford; Mr. Andrew Donaldson, The Gardens, Stoodleigh Court, Tiverton; Mr. William Chapman, West Park, Salisbury; and Mr. J. Lane, Pyrgo Park, all exhibited seedling Melons, none of which were of sufficient merit. Messrs. Veitch & Sons exhibited a Pine Apple from Peru grown at Wycombe Abbey. It has a smooth leaf like the Smooth-leaved Cayenne, but the flavour was inferior. Messrs. Charles Lee & Son, The Vineyard, Hammersmith, sent a fruiting branch of Lawton Blackberry. Mr. Killick of Langley, Maidstone, sent a branch of Loddington Seedling Apple, showing its wonderful fertility. Messrs. Rivers & Son, Sawbridgeworth, sent eight varieties of their new seedling Nectarine, and seven of Peaches. The most remarkable of the former were Humboldt, Byron, Stanwick Elruge, and Dante. They also sent two dishes of Cherries Late Black Bigarreau and Gros Coureut, to which a cultural commendation was awarded. A few dishes of Doyenné d'Été Pears were sent from the garden at Chiswick, which were quite ripe.

FLORAL COMMITTEE.—Dr. Denny in the chair. Lady Dorothy Neville, Dangstein, Petersfield, sent some remarkable Cockscombs, the colour ranging from crimson to orange, and besides the large terminal combs smaller combs were freely produced from the stems of the plants quite down to the soil. A vote of thanks was awarded. A similar award was made to Messrs. James Veitch & Sons, who exhibited wonderfully well-grown examples of *Celosia pyramidalis*. The plants, although only grown in 5-inch pots, were luxuriant and well-furnished pyramids 4 feet high, and were covered with bright crimson plumes. A variety so good as this is and as well grown is very valuable for decorative purposes. Messrs. Veitch also exhibited a new *Torenia Baillonii*, the tube of the flower being almost black, and the segments deep yellow. The Committee desired to see it again. They also exhibited a splendid basket of the dwarf and extremely floriferous hardy shrub *Olearia Haastii*, for which the thanks of the Committee were recorded.

Mr. G. F. Wilson, F.R.S., exhibited a splendid specimen of the Swamp Lily of North America, *L. superbum*, to show that it could be well grown in a pot. The two stems were 8 feet high, and contained about two dozen of beautiful flowers. A vote of thanks was awarded. Blooms of a seedling Lily were submitted by Mr. Wilson as having been raised by Mr. J. H. Mangles, Haslemere, and supposed to be the result of a cross between *L. dahuricum* and *L. elegans*. The flower is 6 inches in diameter, has narrow waved petals, bright yellow, and richly spotted.

A wonderful strong example of *Disa grandiflora* was sent by Mr. Speed from Chatsworth. The stem at the base was quite an inch in diameter, and was surmounted by eight fine flowers. A cultural commendation was awarded. Some fine pans of the same fine terrestrial Orchid were sent by Sir W. Marriott, Bart., Down House, Blandford, who was awarded a vote of thanks.

Mr. H. James, Castle Nursery, Lower Norwood, exhibited the seldom-seen *Oncidium curtum*, the single spike containing upwards of twenty chestnut-coloured flowers with yellow lip; also *O. prætextum superbum*, with very rich brown sepals and yellow lip. Mr. Smith, Caledonian Nursery, Guernsey, sent spikes more than 6 feet high of *Sparaxis pulcherrima* covered with large rosy lilac bells: It is a striking plant, and is probably hardy in Guernsey. It was introduced from South Africa in 1866. A vote of thanks was awarded. Messrs. F. & A. Smith, Dulwich, sent about eighty Balsams, very sturdy well-grown plants with large double flowers

in clear and distinct colour—a very excellent strain, for which the thanks of the Committee were recorded. Mr. G. Scott, The Gardens, Ewell Castle, sent a seedling *Gloxinia* with very pure white throat and blue lobes faintly edged with white. Mr. Cannell sent a splendid collection of cut blooms of *Verbenas* and *Petunias*. Mr. Wills, South Kensington, exhibited a group of double *Stocks* raised from seed sent by M. Doppleb, Erfurt. They are dwarf, and some of the colours are clear and rich.

Mr. Turner, Slough, exhibited a box of twelve blooms of his grand, new, velvety, scarlet *Rose Harrison Weir*. It is somewhat of the *Xavier Olibo* colour and the *Marie Baumann* form, and if its constitution is good, as the character of the blooms suggest it to be, it will be a good *Rose* for years to come. It is strikingly glowing, and the petals are of remarkable substance. It is a splendid addition to an already rich section, and is one of the finest *Roses* ever sent from Slough. A first-class certificate was awarded.

A large assortment of dwarf well-flowered plants of the newer varieties of double and single zonal *Pelargoniums* were sent from Chiswick, also a varied collection of *Abutilons*, floriferous plants of *Torenia Fournieri*, and cut blooms of *Phloxes*, richly coloured *Dianthus* of the *Heddewiggii* type, and cut flowers of *Clove Carnations*.

THE STRAWBERRY AND RASPBERRY CROPS.

THE season here for Strawberries is now drawing to a close, and I am able to speak as to the results. The crop has been very fair, but not equal to the very abundant crop of last year. As I anticipated, a few of the later blooms did not set well.

The weather here since the 20th of June has been fine, and very favourable for the ripening of the fruit. We had several hot days at the end of June with the thermometer over 80°, and two days at 90°, but this great heat fortunately did not continue. From a small bed of Sir J. Paxton I gathered a few quarts of Strawberries, and out of the number there were about a dozen which turned the scale at 1½ oz., which I thought pretty fair for a bed which has been down six years. I have several fresh sorts on trial, and if you think your readers would be likely to be interested in my remarks about them will send a further communication.

A better crop of Raspberries than I have this year never rejoiced the heart of the cultivator, and there has been only one little shower since they came in, so the quality for preserving is excellent.—AMATEUR, Cirencester.

NATIONAL CARNATION AND PICOTEE SOCIETY'S SOUTHERN SHOW.—JULY 23RD.

LAST year the Show was held at the Westminster Aquarium on July 18th, a date which was fully too early for the flowers. This year the Show was held at South Kensington under the auspices of the Royal Horticultural Society, and owing to the great heat that has recently prevailed the fixture proved somewhat late for many of the southern flowers. Still no great injury resulted to the Exhibition, for the chief southern growers, Mr. E. S. Dodwell, Mr. Douglas, and Mr. Turner, exhibited splendid stands; and competitors from Lancashire, Yorkshire, Warwickshire, and Somersetshire staged many charming flowers and shared in the honours of the day. The Exhibition was arranged in the entrance vestibule approach to the Council-room, than which no place could have been better adapted for the purpose, and the Show was excellently managed by Mr. Dodwell and his coadjutors, the flowers being staged in good time and everything worked smoothly and well. It was a beautiful and successful Exhibition, and both as to extent and high quality exceeded the anticipations of the fanciers who attended it from various parts of the country.

CARNATIONS.—In Class A, for twenty-four blooms in not less than twelve varieties, six collections were staged. Mr. Douglas, gardener to F. Whitburn, Esq., Loxford Hall, won first honours with flowers of remarkable beauty. They were smooth, fresh, and in brilliant colour. The varieties were *Eccentric Jack*, *James Taylor*, *Admiral Curzon*, *James Douglas*, *James Cheetham*, *Rev. G. Rudrick*, *Isaac Wilkinson*, *Capt. Stott*, *Sybil*, *Rose of Stapleford*, *Squire Meynell*, *True Briton*, *Earl of Stamford*, *Sarah Payne*, *Bifeman*, *John Keet*, *Dreadnought*, *James Merryweather*, *Lord Lewisham*, *J. D. Hextall*, *The Clipper*, and a magnificent bloom of *John Bailey* which was selected by the Judges as the premier *Carnation* in the Exhibition, and was awarded the prize accordingly. Mr. George Rudd, Undercliffe, Bradford, had the second prize with somewhat smaller flowers, but clear and beautiful in colour. The varieties different from those above named were *John Simonite*, *Juno*, *Mars*, *Sportsman*, *Clipper*, *Satisfaction*, *Sir J. Paxton*, and *Dr. Foster*. Mr. E. S. Dodwell was a very close third. Some seedlings in this stand were highly attractive, and all were, if rather small, highly finished blooms. The fourth prize was awarded to Mr. Jonathan Booth, Manchester, with flowers not so highly dressed as some others yet very fine

In Class B, for twelve dissimilar blooms, eleven collections were staged. The first prize was awarded to Mr. E. S. Dodwell for wonderfully rich blooms of undoubted high quality. The varieties were *Falconbridge*, *Admiral Curzon*, *James Taylor*, *John Keet*, *Jas. Cheetham*, *Marshal Ney*, *Graceless Tom*, and some fine seedlings. Mr. Douglas was second with rather larger flowers but less smooth and massive in petal; the *rose-flake Sybil* was beautiful in this stand. Third honours went to Mr. S. Brown, Crompton Road, Handsworth, Birmingham; and the fourth to Mr. Buttrum, Burgh Mills, Woodbridge, both staging good collections but not elaborately dressed flowers. The fifth prizes in the above classes did not appear to be placed when we left the Exhibition.

In Class C, for six blooms dissimilar, only three collections were staged. Mr. Medhurst, Priory Road, Handsworth, won the first position with *Falconbridge*, *J. D. Hextall*, *Admiral Curzon*, *Mercury*, *Lovely Ann*, and *Florence Nightingale*; second honours going to W. H. Dodwell, Esq., Sidney Villa, Stockwell; and third to J. T. D. Llewellyn, Esq.

In the single specimen classes the following prizes were awarded. *Scarlet Bizarres*.—First, Mr. Douglas with *True Briton*, second Mr. Jonathan Booth with *Garibaldi*, third Mr. John Fletcher with a seedling, fourth, Mr. Brown with *Admiral Curzon*, and fifth Mr. Douglas with the same variety. *Crimson Bizarres*.—First Mr. Douglas with *Jenny Lind*, third with *John Simonite*, fourth with *Capt. Stott*, and fifth with *Lord Milton*; Mr. Turner was second with *John Simonite*. *Pink Bizarres*.—First and fourth Mr. Douglas with *Jas. Taylor*, second Mr. Buttrum with *Sarah Payne*, third and fifth Mr. Hines with *Eccentric Jack*. *Purple Flakes*.—Mr. Douglas was first with *James Douglas*, third and fourth with *Squire Meynell*; and Mr. George Rudd was second and fifth with *Ajax*. A rather weak class, the flowers having lost their freshness. *Scarlet Flakes*.—Mr. Buttrum was first with *Annihilator*; Mr. Douglas second with *Clipper*, third with *John Bailey*, fourth with *Sportsman*, and fifth with *Clipper*. *Rose Flakes*.—Mr. Douglas was first with *Sybil*, second with *John Keet*, and fourth with *Rose of Stapleford*; Mr. Brown was third with *Mrs. Green*, and Mr. E. S. Dodwell fifth with *Rose of Stapleford*. An immense number of blooms were exhibited in these classes, and the Judges must have had considerable difficulty in selecting the prize flowers.

PICOTEEES.—In Class E, for twenty-four blooms in not less than twelve varieties, five collections were staged. Mr. Douglas was first with admirably finished examples of *J. B. Bryant*, *Mary*, *Fanny Helen*, *Mrs. Douglas*, *Ethel*, *Mrs. Niven*, *Mrs. Bower*, *Edith D'Ombra*, *Prima Donna*, *Brunette*, *Miss Wood*, *Zerlina*, *Obadiah*, *Clara*, *Miss Lee*, *John Smith*, *William Summers*, and *Alliance*. Mr. Turner, Slough, was placed second with generally heavier flowers, but not quite so smooth and highly finished. The third prize was awarded to Mr. E. S. Dodwell with rather small but remarkably clean flowers; and the fourth to Mr. Jonathan Booth. Mrs. Fuller, heavy rose-edge, in this collection was remarkably fine. The fifth prize went to Mr. Henry Hooper, Bath.

In Class F, for twelve varieties dissimilar, eleven collections were staged. Mr. Douglas was again in the foremost place with *J. B. Bryant*, *Mary*, *Fanny Helen*, *Miss Wood*, *Zerlina*, *John Smith*, *Mrs. Douglas*, *Edith D'Ombra*, *Minnie*, *Thomas William*, *Brunette*, and *Mrs. Niven*. The grand bloom in this stand of *J. B. Bryant* was placed in the high position of the premier *Picotée* in the Show. The second prize went to Mr. E. S. Dodwell; third to Mr. R. Gorton, Eccles, Lancashire; fourth to Mr. George Rudd; fifth to Mr. S. Brown, Birmingham; and sixth to Mr. B. Simonite.

In Class G, for six blooms, Mr. Medhurst, Wandsworth, was awarded the first prize, and W. H. Dodwell, Esq., the second, both staging clear but rather small flowers.

In the single specimen classes the following prizes were awarded:—*Red Heavy-edged*.—Mr. Douglas was first and second with *John Smith*, and third and fifth with *Princess of Wales*, Mr. Turner being fourth with *Dr. Abercrombie*. *Red Light-edged*.—Mr. Rudd was first and fifth with *Thomas William*, and Mr. E. S. Dodwell was third with the same variety, Mr. Douglas being second and fourth with Mr. Simonite. *Purple Heavy-edged*.—First, Mr. C. Turner with *Mrs. Albert Chancellor* and second with *Zerlina*; third, Mr. E. S. Dodwell with the same variety; fourth, Mr. Douglas with *Mrs. Niven*; and fifth Mr. Buttrum with *Lavinia*. *Purple Light-edged*.—Mr. Douglas was first and fifth with *Mary*, and fourth with *Mrs. Douglas*; Mr. E. S. Dodwell was second with *Mary*, and Mr. Turner third with *Alice*. *Rose or Scarlet Heavy-edged*.—First Mr. C. Turner with *Mrs. Payne*, second Mr. E. S. Dodwell with *Juliana*, third Mr. G. Rudd with *Miss Horner*, and fourth with *Juliana*; fifth *Dr. Abercrombie* with *Lady Louisa*. *Rose or Scarlet Light-edged*.—First Mr. Turner with *Victoria*, second Mr. Douglas with *Miss Wood*, third Mr. Rudd with the same variety, fourth Mr. Hooper with *Lucy*, fifth *Dr. Abercrombie* with *Victoria*. *Yellow Grounds*.—First Mr. Turner with *Hon. Lady Mary Lascelles*, and second with *Prince of Orange*; third Mr. Douglas with the same variety, fourth Mr. Turner with *Alice Waite*, and fifth Mr. Turner with *Prince of Orange*.

In Class I, for twenty-four blooms of selfs, fancies, or yellow

grounds, first Mr. Douglas, second Mr. C. Turner, third Mr. Hooper, Bath, fourth Mr. B. Simonite, and fifth Mr. E. S. Dodwell. Mr. Douglas's flowers were not named, but many of them were wonderfully rich in colour. Mr. Turner's—a beautiful stand—contained Lady Rosebery, Géant des Batailles, Cremorne, Guernsey Belle, Imperial Purple, Fire Eater, King of Yellows, Albert Chancellor, Elysian Beauty, Unexpected, and Christine. In the class for twelve blooms, which brought out ten collections, Mr. Turner again won the chief position with a beautiful stand containing the following that were not represented in the preceding class—namely, Alice Waite, Sentinel, Prince of Orange, Princess Beatrice, and Rose of Denmark. Mr. Catley, Bath, was placed second; Mr. Hooper, Bath, third; and Dr. Abercrombie fourth.

In Class L, for twelve plants in pots not exceeding 8 inches in diameter, Mr. C. Turner was first with a wonderful collection exhibited in 7-inch pots, each plant carrying from ten to twenty fine blooms. All of the varieties were seedlings exhibited for the first time, buff grounds prevailing. First-class certificates were awarded to the Earl of Beaconsfield, reddish buff ground with heavy scarlet flake, a grand flower; to Ophir, clear sulphur, very chaste; to Henry Tait, sulphur ground heavily flaked with deep rose; Eleanor, pale buff faintly edged with rose; and Alice, clear deep sulphur flaked with scarlet. Mr. Turner had also similar awards for the following exhibited as cut blooms—Royal Visit, heavy rose edge, very stout broad petals; and for Mr. Payne, light rose edge, very smooth and clean. Mr. Douglas had the second prize for plants in pots with well-grown examples, containing fine blooms of varieties of established merit.

Mr. Thomas Ware, Tottenham, exhibited a collection of promising seedlings of yellow-ground and self Picotees. Sulphur King was very clear in colour: the flowers are small, but distinct and attractive. This variety and Lady Armitage were also exhibited in pots by Mr. Ware.

The Exhibition was in all respects highly satisfactory, and we trust it will give an impetus to the more extensive cultivation of these beautiful hardy flowers.

NATIONAL ROSE SOCIETY.

OUTLINE SUGGESTIONS AS TO JUDGING AT ROSE SHOWS.

THE following suggestions compiled from expressed opinions of leading rosarians were adopted and confirmed at a meeting of the General Committee of the Society held May 28th, 1878, and presided over by Mr. R. N. G. Baker.

JUDGES.—1, The judges shall, as far as possible, be three in number for all small shows and for all sections of large shows. 2, They shall be selected principally from successful exhibitors. 3, They shall have no manner of interest in the section in which they are judging. 4, They shall begin punctually at the hour appointed.

BOXES.—1, Roses must be judged as they are in the boxes at the time of inspection. No other consideration of any kind is admissible. 2, The boxes should be of the regulation size and shape and set out with moss, unless otherwise specified. Boxes of the regulation size are 4 inches high in front, and 1 foot 6 inches wide.

PRIZES.—1, No exhibitor may obtain more than one prize in the same class. 2, All Roses shown must have been cut from plants which have been the property of the exhibitor for not less than three months previously. 3, All Roses should be correctly named. 4, The showing of duplicates under the same name, still more under a different one, will disqualify the exhibitor. Judges are expected to look closely to this. 5, Judges have power to disqualify for any infringement of the rules on the schedule.

METHOD OF JUDGING.—1, First cast out all bad boxes. 2, Then compare the residue. 3, The following, when necessary, shall be the method of comparison:—*a*, One of the judges should count and designate the good blooms. *b*, The other two should stand by, and stop him when they do not agree. *c*, In every difference of opinion a majority shall decide. *d*, The result of such counting shall form the decision.

POINTS.—Where points are found necessary they shall be allotted as follows:—1, Three points shall be given for the best blooms, two for mediums, one for those not so good but not bad enough to cut out, and an extra point for a very superior bloom. 2, One point shall be taken off from the box for every case of decided badness. 3, Teas and Noisettes shall have no especial favour shown to them as such. 4, Where stands are equal in respect of blooms judges shall proceed to consider the general evenness, variety, arrangement, and setting-up, the boxes being placed side by side and in the same light for that purpose.

DEFINITIONS.—1, A bloom or truss shall be taken to mean a Rose, with or without buds and foliage, as cut from the tree. 2, A good Rose must have form, size, brightness, substance, foliage, and be at the time of judging in the most perfect phase of its possible beauty. 3, A bad Rose.—All blooms or trusses shall be considered bad that have faulty shape, confused centre, or faded colour, and which are either undersized or oversized to the extent

of coarseness or of overblooming. 4, Form shall imply petals abundant and of good substance, regularly and gracefully disposed within a circular symmetrical outline. 5, Brightness shall include freshness of colour, brilliancy, and purity.

NEWCASTLE FLOWER SHOW.

FOR a considerable time little was heard of the Botanical and Horticultural Society of Durham and Northumberland, which has had its head-quarters at Newcastle for more than half a century. During some years anterior to 1875 it was regarded as very local in its nature, and scarcely anything was done to expand its operations and to establish it on a firmer broader basis. By the efforts of a band of earnest able workers, headed by two Honorary Secretaries of remarkable administrative ability, the Society was raised from its former local obscurity, and in an almost incredibly short time was placed in its present commanding position. The progress the Society has made since the present Committee was appointed is something wonderful. Three years ago the number of subscribers was less than four hundred, now its members are four thousand and still increasing. It is evident, too, that the great majority of these take a real interest in the exhibitions, as also indeed do the inhabitants generally of the populous district of which Newcastle is the centre. Unless this were so there could be no such crowds as those which assemble at the shows that are periodically provided.

The Show, which was held in Leazes Park on the 18th and 19th inst., was more numerous attended than was any previous Exhibition, and the greatest satisfaction was generally expressed by the visitors as to the beauty and excellency of the display. In arrangement the Exhibition was unique, and its effect, viewed as a complete picture, was extremely picturesque. The collections were arranged in five tents, each 130 feet by 30. These tents were not isolated in such a manner as to break up the Exhibition, but were placed side by side so as to form one immense marquee. The arrangement will be understood by likening it to a series of large span-roofed plant houses being turned into one by the removal of the inner walls, and supporting the roofs on pillars. The pillars supporting the canvas were not rough and unsightly, as too often is the case, but were made to contribute to the effectiveness of the Exhibition. They were covered with calico, blue and white alternately, and just gave the colours that were wanted to set off the Show to advantage. Besides the great floral pavilion referred to a large circular tent was provided, the centre of which was wholly occupied by a very varied and valuable collection of plants arranged by Messrs. James Veitch & Son, Chelsea. Ferns in this attractive group, which occupied 200 square feet of space, were represented by *Nephrolepis pluma* and *N. davallioides* Youngii, *Niphobolus lingua corymbifera*, *Asplenium ferrugineum*, *Polypodium elegantissimum*, *Rhipidopteris peltata gracillima*, *Lomaria discolor bipinnatifida*, and *Adiantum Luddemannianum*; Orchids by *Anguloa uniflora superba*, *Spathoglottis Petri*, *Odontoglossum Alexandriae* and *Roezlii*, *Cypripedium barbatum longifolium* and *Parishii*, *Dendrochilum filiforme*, *Dendrobium thyrsiflorum*, *Masdevallia Davisii*, *M. Veitchianum*, and *Epidendrum vitellinum majus*. Amongst the Crotons we noticed *Mortii*, *Earl of Derby*, *Challenger*, *Nobilis*, and *Bismarck*. The collection also included *Nepenthes* and fine-foliaged plants in great variety, from stately *Alcasias* to such lowly gems as *Anacatholilus*, *Bertolonias*, &c. The group was brightened by excellent *Tuberous Begonias*, and the fine hardy variegated Grass *Eulalia japonica* showed to great advantage. Never, perhaps, was a collection of plants more closely examined and criticised than by the immense throngs who visited the Show. In the same tent, and in fine contrast to the central group, was a beautiful collection of *Coniferae* exhibited by Mr. Watson, Fenham Nurseries, Newcastle. They were small plants in splendid colour, and the following are quoted as admirable for balcony and other purposes of decoration:—*Cupressus Lawsoniana* and *C. nutkaensis*; *Thuja gigantea*, elegantissima, *semperaeurens*, and *orientalis variegata*; *Piceas nobilis*, *lasiocarpa*, and *Nordmanniana*; *Thujopsis dolabrata variegata* and *borealis*; *Taxus variegata* and *T. hybernica variegata*; *Retinosporas plumosa aurea*, *pisifera lutescens*, and *ericoides*.

Turning to the classes, which numbered seventy-three in the schedule, we found in many of them, especially those for Roses and cut flowers, excellent competition. There was also an extensive display of plants notwithstanding the lateness of the season for fresh flowering specimens, also some good fruit, but the display of this was limited.

PLANTS.—In the first and chief class for twenty plants, ten of them in bloom, staged for effect, only two collections were staged. The £25 prize and the Royal Horticultural Society's silver medal was won by Mr. Tudgey, gardener to J. F. G. Williams, Esq., Henwick Grange, Worcester, with very nearly the same plants that were successful at Preston. They were large, but not fresh, and we thought the Tree Ferns, Cycads, &c., would have looked better had they not been tilted so much, especially as the specimens were not exhibited on stages but on the level ground. The second prize of £15 was won by Mr. T. Wilson, gardener to Mrs. Fleming

Normanby Hall, Middlesborough, with a most creditable collection; indeed, had the plants been effectively arranged in three rows, the centre row of Palms, &c., elevated instead of being placed haphazard in two rows, it is a question if the prizes would not have been reversed. The flowering plants were much fresher than Mr. Tudgey's, notably the Allamandas, Aphelexis, Stephanotis, Ixoras, and Ericas. The foliage plants were very healthy but not large, and were certainly not exhibited to the best advantage, but as far as regards cultivation the plants reflected much credit on the exhibitor. Mr. Wilson also won the chief prizes in the classes for six plants in bloom and for six Ferns. The flowering plants comprised Dipladenias Brearleyana and amabilis, very fine; Clerodendron Balfourianum, Phænocoma prolifera, Tetratheca verticillata, and Dracophyllum gracile. The Ferns were Alsophila australis, Dicksonia antarctica, Cyatheas medullaris and dealbata, and a fine specimen of Lomaria gibba. The plants were remarkably fresh and healthy, and had a spread of fronds of about 5 feet in diameter. The remaining prizes were awarded to Mr. Battensby, a very successful amateur cultivator, and Mr. Methvin for flowering plants; and Mr. Storrie and Mr. Tudgey for Ferns in the order of their names. In the class for six fine-foliaged plants Mr. Methvin won the foremost place with good examples of *Cycas revoluta*, *Yucca aloifolia variegata*, *Cordyline indivisa Veitchii*, and a large *Euphorbia*. Mr. Battensby and Mr. Storrie were placed second and third respectively. *Ericas* were not good, and show *Pelargoniums*, for which good prizes were offered, had lost their freshness. In the last-named class the prizes were awarded to Mr. Adams, Swallow, for a creditable collection, the variety *Ruth* being very beautiful, Mr. Methvin and Mr. Haig respectively. Fancy *Pelargoniums* were also much faded, and *Zonals*, except the first-prize collection of Mr. R. Gardner, had a somewhat drawn appearance; they, however, contributed much to the brightness of the Show. The second and third prizes in the last-named class went to Mr. Alexander, jun., and Mr. Stockley. *Coleuses* were exhibited in considerable numbers. The plants were rather small, but were healthy and in good colour; Messrs. Sherwin, Stockley, and Oliphant were the successful exhibitors. Mr. Forsyth won the chief prize for six *Fuchsias* with well-grown and flowered pyramids not too closely trained. They were about 5 feet high and 3 feet in diameter at the base.

There was good competition in the classes for table plants. The Vice-President's prizes for six plants were won by Mr. Thompson, Mr. Wilson, and Mr. Whiting in the order named. Many of the plants exhibited were fully too large, and on that account, good though they were, they were passed in favour of smaller examples. The first-prize collection in this class consisted of *Areca aurea* and *crinata*, *Cordyline australis*, *Aralia Veitchii*, *Dracæna terminalis*, and *Pandanus Veitchii*, none of them exceeding a foot in height. The Society's prizes were won by Mr. Peter Sherwin, Mr. Kershaw, and Mr. Whiting, the plants in the first-prize collection being again smaller than the others. Besides the plants quoted, *Areca rubra*, *Dracæna gracilis*, *Dracæna Cooperii*, *Corypha australis*, and *Thrinax elegantissima*, and *Reidia glaucescens* were the best and most suitable plants in these classes.

Bedding plants were admirably exhibited in pans 12 inches in diameter by Mr. G. Stockley and Mr. W. Whiting, who were awarded the prizes in the order named. Mr. Stockley's were single plants, and of their kinds were almost faultless. They comprised *Pansies* Duke of Edinburgh, fine purple; and *Duchess of Edinburgh*, excellent white; *Belobelia* Lady Macdonald, yellow *Calceolarias*, scarlet *Geranium* Charley Casbon, dwarf *Tropæolum* Her Majesty, dwarf *Ageratum*, *Dactylis glomerata variegata*, *Mesembryanthemum*, *Centaurea*, and *Mentha*. Mr. Whiting's pans were made up with several plants and were extremely neat, especially *Nertera depressa*, *edum azoideum variegatum*, and *Coleus pictus*. Alpine, rock, and succulent plants were also well exhibited. The prizes for twenty plants were awarded to Mr. Larke and Mr. Brogden.

Classes for plants were provided for amateurs, which at this Show means those who are engaged in industrial pursuits and who grow plants as a hobby or mode of recreation. Very great credit is due to such exhibitors as Messrs. Oliver, Battensby, Deighton, and Gardner for the well-grown specimens they exhibited. The collections included such stove plants as *Allamandas*, *Alocasias*, *Crotons*, *Palms*, including *Cocos Weddelliana*; and of greenhouse plants *Phænocomas*, *Rhynchospermums*, and *Staticeas*, many of which would have done credit to professional gardeners. In the class for fine-foliaged plants equal first prizes were awarded to Mr. Deighton and Mr. Battensby; the chief prize for flowering specimens being won by Mr. Oliver. *Petunias* were rather largely exhibited in this section of the Show. A single striped variety, *Lady James*, was exhibited by every competitor. It is a local variety of considerable merit, and is evidently a great favourite in the district. There was also good competition in the class for double *Petunias*, also for *Fuchsias*, *Geraniums*, and *Ferns*, the latter especially being remarkably well exhibited; but *Roses* in pots were generally poor, the hot weather having proved too much for them.

CUT FLOWERS AND TABLE DECORATIONS.—Foremost in this section were the *Roses*, which formed perhaps the best feature of

the Show; at any rate nothing in the Exhibition attracted more general admiration. In the open class for forty-eight *Roses* in not less than twenty-four varieties Messrs. Cranston & Co. won first honours with blooms that we have rarely if ever seen equalled at so late a period of the year. They were remarkably rich in colour, massive, and symmetrical. Mr. Prince and Messrs. G. Paul & Son had the remaining prizes in this class, both staging excellent stands. Messrs. Cranston & Co. were also in the foremost position for twenty-four *Roses*, followed by Messrs. G. Paul and Son and Mr. Davison. The first prize for twelve yellow *Roses* was won by Messrs. Robert Mack & Son, successors of the late Mr. John Harrison, North of England Rose Nurseries, Catterick Bridge, Yorkshire. For twelve Tea-scented *Roses* Mr. Prince was first with fresh blooms of *Catherine Mermet*, *Margelin Rhoda*, *Souvenir d'Elise*, *Amazon*, *Mons. Furtado*, *Homère*, *Souvenir d'un Ami*, *Perle des Jardins*, *Le Nankin*, *Triomphe de Rennes*, *Souvenir de Madame Pernet*, and *Madame Willermoz*. Messrs. Mack & Son were placed second, and Mr. Davison third. In the class for twelve *Roses* of any variety Messrs. Cranston & Co. were placed first for magnificent blooms of *Alfred Colomb*; Mr. Davison second with the same variety, which has not before been staged in such fine condition this year; and Mr. Prince third with *Marie Baumann* very fine.

In the amateurs' classes Mr. E. R. Whitwell won the chief prize in the class for twenty-four blooms; they were very fine, and were displayed on the velvet-covered stand for which a first prize was granted at the National Rose Show recently held at the Crystal Palace. Mr. Burrell was placed second also with fine blooms, and Mr. Mayo third, an extra prize being granted to Mr. C. Laws. For twelve *Roses* the prizes went to Mr. Laws, Mr. Whitwell, Mr. Sanderson, and Mr. Noble in the order of their names; and for Tea *Roses* to Mr. McMillan, Mr. Mayo, and Mr. Kershaw.

Pinks were wonderfully well exhibited by the leading Northumberland florists, who evidently bestow great attention on these beautiful flowers. The prizes were won by Messrs. Harland, R. Scott, and Jeavons. Of hardy herbaceous flowers there was a great display—quite the best we have seen at any exhibition this year. Nine fine stands of twenty-four varieties of hardy border flowers were exhibited, and the prizes were awarded as follows: Mr. W. H. Wilson first, Mr. C. Wass second, Mr. Spoor, jun., third, Mr. Larke and Mr. Gardner receiving extras. Represented in these boxes were imposing bunches of *Schizanthuses*, *Pinks*, *Delphiniums*, *Liliums*, *Lychnises*, *Veronicas*, *Staticeas*, *Campanulas*, *Antirrhinums*, *Pyrethrums*, *Irises*, *Phloxes*, *Achilleas*, *Thalictrums*, *Lathyruses*, *Pentstemons*, &c. It was quite cheering to see these good old flowers so well grown and cherished.

For the most tastefully arranged table with flowers, plants, and fruit the first prize was awarded to Mr. Thompson, the second to Messrs. Gellender & Sons, and the third to Mr. Methvin. The tables were generally overcrowded, and except the first-prize table too many bright-coloured flowers were employed. The same remarks apply to the epergnes, where the prizes went to those most lightly and elegantly arranged. Baskets of flowers and bouquets were very numerous, but only a few of them possessed merit. The flowers were mostly too closely packed, which imparted a heavy appearance to the arrangements. Messrs. Thompson, Jones, Ison, and Ramshaw were the chief prizewinners in this section of the Show.

FRUIT.—By far the finest fruit was staged by Mr. Jowsey, gardener to G. Gilpin Brown, Esq., Ledbury Park, who won the first prize and Royal Horticultural Society's medal for a collection of six dishes with a good Pine, excellent and highly finished Black Hamburg and Foster's Seedling Grapes, good Peaches and Nectarines, and a small Melon. It was a smart, clean, and highly creditable collection. Mr. Service had the second prize. The same exhibitors held similar positions in the class for four dishes, Mr. Jowsey being again far in advance. Mr. Brown, gardener to Edward Joicey, Esq., Whinney House, Gateshead, won the first prize in the Pine class with a medium-sized well-ripened fruit; and Mr. Jowsey easily won chief honours in the class for four varieties of Grapes with Venn's Muscat, splendid; Buckland Sweetwater, well finished; Black Hamburg, fine; and good Muscats. Mr. Marvin had the first prize for two bunches of white Grapes, and Mr. Aitken won in the black Grape class. Melons were only moderate, Peaches good but not well coloured. Nectarines small and Cherries poor. A very large number of Cucumbers were staged, but all of them were too large and too old to be regarded as superior. A curious brace of twin Cucumbers were exhibited by Rev. R. F. Wheeler, Whitty.

We must not omit notice of a magnificent bunch of Venn's Muscat Grape, for which Mr. Jowsey was awarded an extra prize. It was probably the finest bunch of the variety that has yet been exhibited. It weighed about 3 lbs., and as regards shape of bunch and size, colour and regularity of berries, was about faultless. An extra prize of £3 was deservedly awarded to Mr. Witherspoon, Chester-le-Street, for a collection of fruit trees in tubs, consisting of Peaches, Nectarines, Early Harvest Apple, Mulberry, and Vines, the latter being in pots. All were bearing excellent crops, and the foliage was remarkably healthy and clean.

Amongst miscellaneous exhibits we observed boxes of Roses and cut spikes of Lilioms, Delphiniums, &c., from Messrs. Stuart and Mein, Kelso; weeping Wellingtonias from Messrs. Little and Ballantyne, Carlisle; fine Agaves from Mr. Alexander, jun., Hexham; a heating apparatus at work from Messrs. Dinning & Cook, Newcastle, the boiler being entirely above ground and the circulation excellent; and useful and economical garden structures from Mr. John Bowman.

After the judging was completed an excellent luncheon was provided. The Mayor of Newcastle occupied the chair, and was supported by the High Sheriff of Northumberland, the Sheriff of Newcastle, the Mayor of Yarrow, the Vicar of Newcastle, the ex-Lord Mayor of York, and other gentlemen who take an interest in the Society's welfare. Col. Joicey, the President, was unable to attend, but he sent excellent fruit for the dessert. The speeches were refreshingly horticultural in tone, and the Show was in all respects a great success. The second day was declared a holiday by the Mayor, the principal tradesmen obeying his mandate by closing their shops. The weather was brilliant, and vast crowds filled the tents to overflowing. By the exertions of Messrs. Taylor and French, the Hon. Secretaries, a hard-working Executive Committee, and an industrious Acting Secretary, Mr. Gillespie, the arrangements were rendered complete, and all who aided at the Show had extended to them the utmost courtesy.

NOTES AND GLEANINGS.

THE Council of the Royal Horticultural Society have fixed the MEETINGS OF THE SOCIETY for 1879 as follow:—January 14th, February 11th, March 11th and 25th, April 8th and 22nd, May 13th and 27th, June 10th and 24th, July 8th and 22nd, August 12th and 26th, September 16th, October 14th, November 18th, December 16th. The Great Summer Show will be held on the 27th, 28th, 29th, and 30th of May. The Rose Show and the Show of the Pelargonium Society on June 24th.

— A GARDENER who has recently visited Glamis Castle informs us that some of the finest bunches of the DUKE OF BUCLEUCH GRAPE that have ever been produced are fast advancing to maturity in the vineries there. They are large, handsome, full, well-shouldered bunches that even Mr. Johnston may be proud of. This Grape does not spot to any extent at Glamis, but it gives some trouble by the berries cracking.

— THE weather in the north of England has for some time past been extremely hot and dry, and rain is much more urgently needed than in the metropolitan district. When visiting the gardens at Lambton Castle, Durham, on the 19th inst. we found the ground cracking extensively and the crops languishing. No rain had fallen since the flower-garden plants were bedded out. The thermometer in the shade was 84°. In Lincolnshire we found it still hotter and drier. The crops there are shrivelling up, and Apples are falling from the trees until they cover the ground. On several days the thermometer in the shade has exceeded 90°; and on the 21st inst. a corrected thermometer in the Hon. A. Leslie Melville's garden at Brans-ton registered the extraordinary heat of 94° in the shade and 120° in the sun. Not a drop of rain has fallen since June 17th, and then only a slight shower.

— THE ORCHARD HOUSES AT SAWBRIDGEWORTH are now well worthy of a visit, and those interested in the culture of fruit under glass will derive both pleasure and profitable instruction by a visit to this renowned establishment. The forced Peaches and Nectarines are now nearly past, and those under cool treatment are beginning to ripen. The Cherry house is in perfection, and is of itself a study to those who care to make themselves acquainted with the finest varieties of this delicious fruit.

— THE Vegetable Marrows and Tomatoes in the Fulham market grounds, which were threatened by the continuation of rain in June, are now recovering, and hopes are entertained of a good crop; but French Beans are an utter failure in many instances, the rain caused the seed to decay, and what few plants struggled to the surface the slugs destroyed. Onions are a failure in many places also.

— THE beds of ANNUALS on Messrs. Sutton & Sons' seed grounds at Reading, seen from the Great Western Railway, look remarkably bright and attractive. The strains of Asters, Stocks, Marigolds, &c., appear to be very good, and there are some beds of Nasturtiums which look wonderfully bright. The latter being very dwarf and compact ought to be an excellent substitute for Geraniums where scarce, and are also very useful where variety of bedding plants is required. They succeed remarkably well on a poor soil, and remain in bloom a considerable period, very hot and dry weather evi-

dently suiting them. They belong to the Tom Thumb section and can be had of the following colours: salmon and maroon, Crystal Palace Gem; scarlet, King of Tom Thumbs; crimson, black, King Theodore; creamy-white, Pearl; spotted, rose, and bluish-rose, *Cærulea rosea*.

— THE Royal Water Lily, *VICTORIA REGIA*, in the aquatic house in the Royal Botanic Society's Garden, Regent's Park, is this year unusually luxuriant. From a small seed sown in January a plant is produced of gigantic proportions, the six grand leaves almost covering the surface of the large tank. In a short time this fine plant will produce flowers, and will be an object of considerable attraction. Other aquatics in the same house are in a most satisfactory condition.

— MR. NUNNS of the Victoria Nursery, Beckenham, who contributed a very effective group of Palms, Crotons, Ficuses, Ferns, and other decorative plants at the Beckenham Exhibition on Saturday, a year or two since held the charge of the extensive gardens of Beckenham Place, where the recent show was held. Since Mr. Nunn's removal from these gardens he has built himself several substantial light and useful glass houses 60 feet long, in which he grows almost every requisite for decorative display. In the first house we visited the roof was covered with *Stephanotis floribunda*, which was blooming profusely at Easter and on which at the present time are a quantity of its waxy white trusses. Underneath are plants of *Eucharis amazonica* plentifully in flower. A second house was well filled with *Petunias*, *Fuchsias*, double and single *Geraniums*, *Carnations*, and other flowering plants. In a third we observed an extensive batch of the double Ivy-leaf *Geranium* *König Albert*, which Mr. Nunn considers one of the best Ivy-leaves for vases and baskets. Another house was partially devoted to Cucumbers, the fruit of which was hanging in plenty. We also observed large batches of healthy *Epiphyllums*, young *Fuchsias*, especially the distinct and decorative variety *Earl of Beaconsfield*, and immense quantities of *Adiantums* *Capillus-Veneris*, *cuneatum*, and *gracillimum*.

— THE OAKS in many parts of the country, and notably so in Shropshire, present a rather unusual appearance from the fact that they are making a second growth. This is very noticeable in low-lying moist situations. The young growth has completely changed the appearance of the trees, the colour now being a mixture of light and the usual dark green. The ELMS and other trees are also making a second growth, but not in such a marked degree as with the Oaks. It will be interesting to note the tinges assumed by the old and young growth when changing in the autumn.

— AMERICAN cultivators appear to be using PARIS GREEN, which they found a specific against the Potato beetle, for the destruction of other insects on plants and trees. In applying the insecticide some prefer to mix the green with water, others with flour or plaster. Either is quite effectual. In the one case a watering-pot that will hold a pail of water, in the other a sieve of some kind is needed. Any tin vessel with holes punched in the bottom will serve. A flour-sieve with a covering of muslin or paper tied about it answers well enough. To twenty parts of cheap flour or plaster add one part of green and mix thoroughly. Sift this upon the leaves before sunrise while they are filmed with dew. It is labour and material lost to wait until the dew has been in part or wholly evaporated, since there is nothing to hold the dry powder and the first breeze blows it away. Or a heaping tablespoonful of Paris green may be stirred into a pailful of water and applied with a syringe or brush, stirring it the while, as the green is not soluble in water.

— THROUGHOUT France GARDENING IS PRACTICALLY TAUGHT in the primary and elementary schools. There are at present 28,000 of these schools, each of which has a garden attached to it, and is under the care of a master capable of imparting a knowledge of the first principles of horticulture.

— AS an illustration of GERMAN FRUIT CULTURE as a profitable industry, and also as furnishing an illustration of the beneficial results that arise from small proprietorships, the little village of Werder, near Potsdam in Germany, celebrated for the quality of its fruit, is, says the *American Cultivator*, a striking example. The population of this parish is only about 3000, and its area is 2300 acres, whereof 975 acres are devoted to fruit culture. The natural soil in most places is very poor, and has only been brought to its present fertile condition by the indomitable thrift and perseverance of its owners. These 975 acres are distributed among some 550 owners, so that each cultivator has, on an average, about 1½ acre of land. The

total value of the fruit crops of Werder varies, of course, according to the season. In 1875 something like 2,500,000 gallons of fruit were marketed at Berlin.

ANGULOA CLOWESII.

THE subject of our present illustration belongs to a small genus of terrestrial Orchids from the forests of tropical America, but in regions of considerable elevation. The species

are for the most part strong growers, and do not as a rule retain their leaves more than two years, but as they make fresh leaves every season there is no lack of foliage on well-grown plants. They make bold, much-plaited, dark green leaves, and produce their flowers upon short stems, which proceed from the base of the young growths, beginning to show themselves very soon after growth commences. The flowers are mostly solitary, Tulip-like, and curiously scented. In the species figured the colour is a rich deep golden yellow. They have a

Fig. 10.—ANGULOA CLOWESII.

curious moving lip, which the ladies say has an exact resemblance to a baby lying in a cradle, and as they are supposed to be the best judges of such matters it would ill become us to contradict such authority.

In the matter of cultivation Anguloas are very accommodating; they love good drainage and an abundant supply of water. Pot them firmly in rough fibrous peat and place them in the cool house, and if in a somewhat dark corner so much the better. After growth is finished very little water will suffice to keep the plants in health.

The engraving (fig. 10) is from a photograph of the magnificent plant belonging to O. O. Wrigley, Esq., Bridge Hall, Bury, to which the Veitch memorial medal was awarded at the Manchester Show. The foliage of this remarkably fine

plant when seen at Manchester was 2 feet long, 6 inches broad, and had a spread of nearly 4 feet. The number of flowers expanded was forty-four, all of large size and rich colour. The plant was grown by Mr. Hubbersty, Mr. Wrigley's skilful gardener.

CLEMATISES—SUTTONS' DARK RED BEET.

CLEMATISES are favourite flowers in the well-kept garden of the Rev. C. P. Peters, Pitchford, Salop. They are trained in various ways, and will soon present a fine appearance festooned at the back of an extremely well-managed flower garden. The prettiest effect, however, is obtained by allowing plants of *C. Jackmanii* and *C. rubro-vioacea* to ramble at their will

over some specimens of *Acer Negundo variegata*. The rich colours of the Clematises contrast admirably with the beautifully variegated *Acer*, and neither loses anything from the fact of being among herbaceous plants and highly-coloured annuals. Other favourite Clematises here are Lord Londesborough, Lady Londesborough, Lord Napier, Miss Bateman, Prince of Wales, and *lanuginosa candida*.

A favourite bedding plant in the above garden with both the reverend owner and his gardener, Mr. Morris, is Suttons' Dark Red Beet, and it certainly deserves much praise. The colour is brighter, deeper, and quite superior to any of its rivals, such as *Iresine*, *Coleus*, &c., and the plants are much more easy to cultivate. The treatment given, and which greatly contributes to success, is as follows:—The seed is sown in June (later will do) in some spare plot; the plants are thinned out slightly, some being transplanted if required when large enough to handle, and are left till required for putting out with the winter bedding plants. Care is taken to plant as much as possible in a position to be left for working-in with the bedding plants the following summer, using the Beet in lines, circles, &c. In summer the flowering shoots are kept well but not closely pinched back, and the result is the gradual merging of the vegetable into an extremely compact and pleasing bedding plant. This plan has been tried for four consecutive seasons with unfailing success. The only objection ever offered to Beet as a bedding plant is the fact of its being "so common;" but when treated as above, one, on first seeing it, asks, "Is it a Beet?" and if therefore given its botanical name, *Beta vulgaris*, Suttonii it would have the effect of mystifying those who sometimes offer frivolous objections to the use of simply grown plants. Other varieties of Beet doubtless can be similarly grown, but Sutton's is the favourite at Pitchford rectory.—W. IGGULDEN, *Orsett Hall*.

BECKENHAM AND ALEXANDRA HORTICULTURAL SOCIETY.—JULY 20TH.

IN visiting suburban horticultural exhibitions we very rarely find any but that are considerably enhanced in beauty by choice groups of new and rare plants lent by our leading nurserymen. This was not the case with the Beckenham Show, for with the exception of some boxes of cut flowers from Mr. Cannell, Swanley, and some decorative plants sent by Mr. Nunn, Victoria Nursery, Beckenham, the productions exhibited were in competition. The schedule provided seventy-one classes, forty-six of which were appropriated to cottagers. The cottagers' productions were far above the average quality, and the classes were so spiritedly contested that when Sir Charles Mills, M.P., awarded the prizes the same evening several of the successful exhibitors received from eighteen to twenty prizes, and amongst these were Messrs. Leach, Horlock, Sales, and Morrison. Some very pretty miniature model gardens were exhibited by Mr. Dace, 47, Albert Road, Penge, and Mr. Morrison, who were placed first and second respectively, and Messrs. Rogers and Greenfield equal thirds. Both cut flowers and the general appearance of the window plants and other productions spoke of the great care which had been bestowed upon them by the exhibitors.

In the gardeners' exhibits there was room for improvement, which very possibly we shall see at the next annual Show, for with many it was their first attempt at exhibiting. Mr. Ridgewell, gardener to F. R. Glover, Esq., Chestnuts, Beckenham, received the first prize for six fine-foliage plants, Mr. E. Brabon, gardener to F. P. Alliston, Esq., The Ferns, being placed second, and Mr. Harpin, gardener to J. E. Ratcliffe, Esq., Broomhill, third. Messrs. Ridgewell, Harpin, and Brabon were also first, second, and third respectively for six stove plants; and for six flowering plants Mr. G. Westcott, gardener to Mrs. Crane, Westgate, received the first prize for fairly bloomed plants of *Allamanda Schottii*, *Oncidium crispum*, *Begonia weltoniensis*, a *Vinca*, *Hydrangea*, and *Agapanthus*. Some small but very neat exotic Ferns were exhibited by Mr. Harpin and Mr. Brabon, who were placed in the order of their names, and Mr. Brabon received an extra prize for six well-flowered Tuberous Begonias, which were very effective. Mr. Harpin's Zonal Geraniums were very good, and received the first prize.

Vegetables came from Mr. Poffley, gardener to A. McKinlay, Esq., Mr. E. Brabon, and Mr. J. Brabon, who were first, second, and third respectively, and the Messrs. Brabons with Mr. Harpin shared the fruit prizes.

Mr. Cannell's cut blooms of both double and single Pelargoniums, the highly attractive *P. echinatum*, *Verbenas*, and the White, Striped, and Salmon *Vesuvius* commanded much attention from the numerous visitors, which always abound when an exhibition can be held on a Saturday afternoon. The Show was held in a well-wooded park belonging to Spencer Burton, Esq.

The Committee, of which Mr. McKinlay (of Potato renown) is

the energetic Hon. Sec., are to be congratulated on their success, for if it is well to improve the Pines, Grapes, and Orchids of the rich it is surely well to improve the cottage gardens of the industrial classes.

REPORT ON FILBERTS

Grown in the Royal Horticultural Society's Garden, Chiswick.

By A. F. BARRON.

POPULARLY they are pretty correctly classed as follows:—

1. **FILBERTS.**—Varieties of oblong shape like that of the finger nails, and generally remaining in the husks: Bond, Barr's Espagnole, Barcelone de Loddiges, Cosford, A Grappes, A Grappes précoce, Frizzled, Lambert's Hartington Prolific, Lichtenstein's Zellernuss, Siegel's Zellernuss, Red Filbert, White Filbert.

2. **COBS.**—Varieties of short broad shape like that of the thumbnail, rather large, and with thick shells; generally falling freely from the husk: Atlas, Burchardt's, Merveille de Bolwiller, Wiesmann's Zellernuss.

3. **NUTS.**—All the smaller varieties without husks: Aveline de Provence, *Corylus arborescens*, *C. laciniatus*, à Fruits striées, Small Cluster, St. Grisier.

Atlas.—*Syns.*, Downtown, *Corylus algeriensis*.—Husk hairy, about equal in length to the nut, generally divided into two parts, deeply toothed, and pressing closely to the nut, of a dark brown colour. Nut large, broad, angular, with a broad irregular base, parting freely from the husks when ripe; shell dark brown, very thick and hard; kernel large, full, and of excellent quality. Plant of strong growth, fruits freely; ripe midseason. A splendid Nut of the Cob class.

Aveline de Provence.—Husk hairy, a little longer than the nut, light-coloured, sharply but not deeply toothed. Nut short, pointed, with a rather broad base, of a light grey colour, and parting freely from the husk when ripe; shell very thick and hard; kernel full. Plant of moderate growth, a great cropper, but late in ripening. This appears to be the same as the light-coloured variety of the Barcelona Nuts of commerce.

Aveline Rouge.—See Red Filbert.

Barcelona Blanc.—See White Filbert.

Barcelone de Loddiges.—Husk very large, full, covered with short hairs, twice the length of the nut, which in some cases it completely covers, sharply serrated, light-coloured. Nut of medium size, being almost hidden in the large husk, angular, bluntly pointed at both ends, dark-coloured; shell very thick, hard; kernel full; grows in clusters of five or six. Plant of very robust growth, with large dark green leaves; a moderate cropper; fruit ripens early. Very distinct but too small.

Barr's Espagnole.—Husk downy, short, about two-thirds the length of the nut, which it presses closely, deeply and irregularly toothed, of a dull grey colour. Nut much exposed, short, having a broad base, and tapering very nearly to the apex; shell downy, but very hard, of a dull grey colour; grows in clusters of from four to six. Plant of medium growth; moderate cropper; ripens late.

Burr or Barn.—Not fruited.

Bizarre.—Not fruited.

Bond.—Husk downy, about one-third longer than the nut, very deeply toothed, the segments very long and narrow. Nut exposed, medium size, ovate, light-coloured, very soft and downy; shell soft, may be pierced with the thumbnail; kernel small; grows in clusters of from four to six. Plant of slender growth; midseason; prolific; does not keep well.

Cape Nut.—See Frizzled Filbert.

Burchardt's.—Husk downy, a little longer than the nut, deeply toothed, dark-coloured. Nut medium-sized, very broad, the breadth exceeding the height, angular, or nearly square, with a broad flat base, light-coloured; shell thick; kernel very large full, of excellent flavour. Plant of moderate growth; late-growing; fruit ripens early.

Corylus laciniatus.—Husk very small, lacinated to the very base, and much reflexed. Nut quite exposed, small, short, somewhat flattened, but of even regular form, of a pale grey colour; shell very thick and hard; grows in clusters of from three to five. Plant of slender growth; leaves deeply cut or lacinated; fruits freely. This appears to be merely a cultivated variety of the ordinary Hazel (*Corylus avellana*). Ornamental.

C. algeriensis.—See Atlas.

C. arborescens.—Husk small, downy, about the same length as the nut, lacinated to nearly the base; the segments long, linear, and reflexed. Nut small, does not part freely from the husk, flattened and broadly pointed, light-coloured; shell

very thick and hard; kernel full. Grows in clusters of five or six. Plant of moderate growth. A worthless variety.

Cosford.—*Syns.*, Miss Young's, Thin-shelled.—Husk downy, about equal in length to the nut, very close fitting, toothed, light-coloured. Nut large, oblong, rounded, remaining in the husk, of a warm light colour; shell very thin, may be easily broken between the thumb and fingers; kernel large, full, of excellent quality; grows in clusters of from three to five. Plant of moderate growth; leaves pale green; fruits freely; ripe midseason. One of the finest Filberts in cultivation.

Downton.—See Atlas.

Downton Large Square.—See Atlas.

Franche rouge.—See Red Filbert.

Frizzled.—*Syn.*, Cape Nut.—Husk large, downy, somewhat exceeding the length of the nut, pale or dull coloured, deeply laciniated or toothed, and reflexed to one-half its length, giving it a frizzled or frizzled appearance, and thus exposing the nut. Nut oblong, from 1 to 1½ inch, somewhat flattened and broadly pointed; shell pale, thick; kernel large, full, of fine flavour; grows in clusters of four or five. Plant of moderate growth; free fruiting; late in ripening. A very pretty and distinct variety.

A Fruits striées.—Husk downy, longer than nut, deeply toothed or laciniated, and opening away or reflexing, thus exposing the nut when ripening. Nut small, long, and narrow, with a flat point; base irregular, pointed, lightly coloured; shell thin, hard; grows in clusters of three to six. Plant moderately robust, grows late; free-fruiting; ripens early. A very pretty nut but too small.

A Grappes.—Husk hairy, about the same length as the nut, in two parts, which spread out from the nut as it approaches ripeness, sharply serrated. Nut quite exposed, small, long, flattened, spoon-shaped, light-coloured; shell thick and hard; kernel full; grows in clusters of from five to eight. Strong grower; ripens late.

A Grappes précoce.—Husk large, very downy, about the same length as the nut, very deeply toothed and partly reflexed. Nut small, long, narrow, and gradually flattened towards the apex like a wedge; shell downy, pale grey, thin; grows in clusters of from six to eight. Plant of slender growth; prolific; early.

Grosse précoce de Frauendorf.—See Red Filbert.

Grosse ronde de Piedmont.—See White Filbert.

A Gros Fruits Noir.—Husk very dark-coloured, hairy, nearly as long as the nut, in two divisions, fitting very close to the nut, thereby giving it a bare appearance. Nut of medium size, long, the base narrow, widening to the apex, dark or dull coloured; shell very thick; kernel small. A moderate grower; prolific. Does not ripen well.

Hartington Prolific.—Husk hairy, one-third longer than nut, the extending portion deeply laciniated and reflexed. Nut small, long, narrow, and pointed at both ends, irregular, light-coloured; shell thin; kernel full, fine flavour; grows in clusters of six or seven. Plant of moderate growth; very prolific and very early. The earliest nut to ripen, but too small.

Jeeves' Seedling.—See Siegel's Zellernuss.

Kentish Cob.—See Lambert's Filbert.

Knight's Small.—See White Filbert.

Lambert's Filbert.—*Syns.*, Kentish Cob, Filbert Cob, Spanische Nut.—Husk downy, large, about one-third longer than the nut, close-fitting, and over the apex, of which it is occasionally contracted so as to enclose the nut, very slightly toothed, dull-coloured. Nut large, remaining in the husk, oblong, pointed, somewhat furrowed and irregular, of a dull grey colour; shell thick; kernel full; grows in clusters of five or six. Plant of medium growth, a very great and certain cropper; fruit ripens midseason. One of the very best Filberts in cultivation. Very largely grown in Kent under the name of Kentish Cob.

Lichtenstein's Zellernuss.—Husk downy, large, a little longer than the nut, bluntly toothed, the segments slightly reflexed. Nut medium size, long, pointed at both ends, of irregular angular shape, and nearly closed in by the husk, of a dull grey colour; shell very hard; grows in small clusters. Plant of strong late growth; ripens late.

Miss Young's.—See Cosford.

Merveille de Bolwiller.—Husk downy, about one-third longer than the nut, in two divisions, deeply and irregularly toothed, and pressing closely to the nut. Nut large, rounded at base, very broad, the breadth nearly equal to the height,

tapering to a broad point, very regular and uniform, light-coloured; shell thick; kernel large, fine flavour. Plant of strong growth, grows late; prolific; fruit ripens midseason. A very handsome and excellent variety.

Purple-leaved.—This is merely a purple-leaved variety of the Red Filbert. A very ornamental plant.

Red Filbert.—*Syns.*, Aveline rouge, Franche rouge, Rouge d'Algers, Grosse précoce de Frauendorf.—Husk downy, of a reddish-brown colour, nearly twice the length of the nut, round the apex of which it is contracted, thereby enclosing the nut. Nut remaining in the husk, small, long, and pointed at both ends; shell thin but hard; kernel very full, having a red skin, finely flavoured. Plant of slender growth; very free-fruiting; ripe midseason. A very excellent variety.

Rouge d'Algers.—See Red Filbert.

Small Cluster.—Husk small, hairy, deeply divided into two parts, of about the same length as the nut, toothed, and pressing closely to the nut. Nut small, short, with a broad pointed base, light-coloured; shell thin but hard; kernel full; grows in clusters of from eight to ten; slender-growing; prolific, but too small. Worthless.

Siegel's Zellernuss.—*Syns.*, Sickler's Zellernuss, Jeeves' Seedling.—Husk downy, short, extending to three-quarters the length of the nut, very deeply toothed and reflexed, the nut thereby being almost entirely exposed. Nut large, oblong, with a broad rounded base, becoming flattened towards the apex, light-coloured; shell thin; kernel large, full; grows in small clusters. Moderate grower; ripe midseason.

Spanish Nut.—See Lambert's.

St. Grisier.—Husk downy, or having only short hairs, a little longer than the nut, which it presses closely, sharply toothed. Nut of medium size, short, roundish, with a broad base, of a dark brown or reddish colour; shell thick but easily broken; kernel large, full, of excellent flavour; grows in clusters of three to six. Plant of slender growth; very prolific; ripens early. This appears to be the same as the reddish-coloured Barcelona Nut of commerce; perhaps the finest flavoured of all Nuts.

Weismann's Zellernuss.—This is very similar to Merveille de Bolwiller, but larger.

White Filbert.—*Syns.*, Knight's Small, Barcelone Blanc, Grosse ronde de Piedmont.—Husk hairy, light-coloured, nearly twice the length of the nut, round the apex of which it is contracted, thereby enclosing it; it frequently bursts a little on one side, whereby the nut is exposed. Nut long, small, remaining in the husk, pointed at both ends; shell thin, very firm; kernel large, full, of fine quality; grows in clusters of from five to eight. Plant of slender growth; a very heavy and certain cropper; fruit ripens midseason. A very excellent and useful variety.

LIST OF SELECT NUTS FOR GENERAL CULTIVATION.—Atlas, Cosford, Lambert's Merveille de Bolwiller, Siegel's Zellernuss, White Filbert.—(*Journal of the Royal Horticultural Society.*)

DOUBLE AZALEAS FOR CUT FLOWERS, &c.

As a rule, double or semi-double flowers last longer in a fresh condition, either when the flowers are left on the plant or when cut, than do single flowers of the same species. This is very strikingly exemplified in Azaleas; and though it cannot perhaps be said that double Azaleas are more beautiful or generally effective than single ones, neither can it be said that they are less so. The doubles very far surpass the singles in the length of time they remain in bloom, as well as for their endurance when cut for bouquets and vases. On this account the culture of a fair proportion of them is very desirable both as decorative plants and for affording sprays of bloom for mixing with other flowers in vases, and for "wiring" in single blooms for bouquets. Indeed very few plants excel them for these purposes, especially when it is considered that their flowering period can be extended from October to June, and that the colour of their flowers ranges from the purest white to nearly crimson. The whites are especially useful for bouquets, from the fact that some of them, such as Maria Waterougal, are small.

To all who have a supply of flowering plants and cut flowers to keep up in the autumn and winter months, as well as early spring, double Azaleas are most useful. The length of time they remain in bloom is remarkable. On the 3rd of April we had a plant of the semi-double and charming Souvenir de Prince Albert in bloom that has outlasted several sets of single varieties growing in the same house. The same may be said

of the following selection, which can be strongly recommended for the qualities and purposes we have referred to:—

A. Borsig.—Pure white; medium size. Can be had in bloom by the end of October.

Charles Leirens.—Very dark salmon, with crimson blotch on upper petals. Blooms in October.

Flag of Truce.—Splendid, large, pure white; vigorous habit. Excellent for February and March.

Imbricata.—As double as a Balsam; said to be the finest of its class. We can only speak of a small plant that bloomed in February—appeared not so pure a white as it has been described.

Maria Waterougal.—Pure white, flowers small and neat, and valuable for bouquets. Can be flowered in winter.

Narcissiflora.—White, and the earliest of all the double varieties. Can be bloomed easily in October.

Souvenir de Prince Albert.—In every respect a charming variety, and can be flowered in winter. A beautiful rosy peach, broadly margined with white. Lasts a very long time in bloom.

These varieties are well worthy of special culture for winter and early spring decoration; and for cutting at a season when white flowers are scarce the whites are invaluable.

At no other season are Azaleas more enjoyable than in winter and early spring, when they last longer in bloom than later in the season. By growing a few of President Van der Hecke, a single variety, and *Narcissiflora*, to come into bloom early in October, there is no great difficulty in prolonging the Azalea season to eight months of the year. Of course for this purpose it requires that a growth should be forced on different sets of plants in succession, so as to be easily got into bloom at their respective seasons.—D. T. (in *The Gardener*).

BOXWOOD.

FOR some years past the supply of this important wood has diminished in quantity and risen in price. It is derived from the forests of the Caucasus, Armenia, and the Caspian shores. The wood of best quality comes from the Black Sea forests, and is principally shipped from the port of Poti. The produce of the Caspian forests, known in the trade as "Persian" wood, until last year was also exported through the Black Sea from Taganrog. This found its way after the commencement of the war *via* the Volga Canal to St. Petersburg. The produce of the Caspian forests is softer and inferior in quality to that of the Black Sea. It is a matter of interest to see whether one result of the war will be to open those Black Sea forests which the Russian Government has hitherto kept rigorously closed.

The falling-off of the supply has led meanwhile to various attempts to find substitutes for boxwood for many purposes. Messrs. Joseph Gardener & Sons of Liverpool have introduced with some success *Cornel* (*Cornus florida*) and *Persimmon* (*Diospyros virginiana*) for shuttle-making, for which purpose hitherto box has been in great demand.

The diminished supply has also drawn attention to the Himalayas as a source of supply. Dr. Brandis, the Inspector-General of forests in India, has corresponded with Messrs. Gardener on the subject. I am informed, however, by Mr. Godfrey Saunders of this firm that "the difficulty of transit from the mountains to the seaboard appears to be the great obstacle, and in addition the possible supply appears to be much smaller than is furnished from existing sources."

Mr. Robson J. Scott has presented to our museums blocks prepared for wood engraving of Hawthorn, which he states "is by far the best wood, after box, that I have had the opportunity of testing."—(*Kew Report*.)

THE INTRODUCTION OF FOREIGN TREES INTO GREAT BRITAIN.

ALL the timber required in this country for building and fuel was of home growth till about the time of Henry VIII. Holinshed informs us that in the same reign plantations of trees began to be made for the purpose of keeping up the supply, and inquiries to be made respecting the productions of other countries, and as objects of curiosity, more than from any idea of cultivating them for their commercial value, some specimens made their appearance in England. Before this date, in the early history of the country, when Britain was a Roman province, the conquerors had enriched the soil of England with many trees not indigenous to it. According to Whitaker, the Romans brought over the Plane, the Lime, the Box, the Elm, and the Poplar. The Apple is supposed to have

been introduced into Britain by the first colonies of the natives; and among fruit trees we owe to the Romans the addition of the Pear, the Damson, the Cherry, Peach, Apricot, Quince, Mulberry, Chestnut, and Fig. It is only to be expected that where there are such meagre historical records there should be some difference of opinion among the learned; but the above are generally accepted as facts, though secondary evidence has in some cases to be relied upon, none other being forthcoming. The monks were often laborious arborists, and if not to the Romans, we owe to them the Sweet Bay and the Arbutus. Dr. Walker thinks that the Elm was brought over from Palestine by the Crusaders. In the beginning of the thirteenth century the Apple appears to have been cultivated to some extent in Norfolk, for in 1205 Robert de Evermere held his lordship in that county by payment of two hundred Pearmain and four hogsheads of wine. Gerard's catalogue of trees, dated 1596, contains the Laburnum, the Judas Tree, the Laurustinus, the White Mulberry, the Nettle Tree, the Pinaster, the Arbor-Vitæ, the Yucca, &c., as being among the foreign trees in his garden in Holborn. It is not known for certain whether Raleigh brought over any hardy trees from America, though it is probable he did so, as he introduced the Cherry tree into Ireland, and his manor at Sherborne is said to have been magnificently embellished with woods and gardens.

Sixteen foreign woody plants were introduced into England in 1548, but the names of the introducers or first cultivators are almost entirely unknown. Among these trees were the Sweet Bay, Mulberry, Platanus, Stone Pine, common Spruce, Fir, Cypress, and the Savin Juniper. From 1551 to 1596, during the reign of Mary and the greater part of that of Elizabeth, twenty-four plants are recorded, among which were the Peach, the Nectarine, and the Walnut from Persia; also the Quince and the Quercus ilex, or Evergreen Oak. The names of the introducers, says Loudon, are not known, with few exceptions, such as that of Hugh Morgan, apothecary to Queen Elizabeth; Gray, a London apothecary; L'Obel, afterwards apothecary to James I.; and Dr. Grindal, then Bishop of London. According to the same authority, from 1596 to the end of the century forty-six different species were introduced, and upwards of thirty of these were first recorded by Gerard. Among these were the English and Scotch Laburnums, the common Syringa, &c. The total number of foreign woody plants which are known to have been cultivated in Britain during the sixteenth century is only eighty-four, exclusive of two varieties of the Laurustinus and nine of the Phillyrea. Although it is impossible at this distance of time to ascertain the names of all the persons to whom we are indebted for the introduction of these plants—and probably many were masters of ships, or even common seamen—it is certain that the merit of the first cultivation of the greater part of them belongs decidedly to Gerard, whose garden was situated between Ely Place and Field Lane, Holborn, London.

The great introducer of foreign trees in the seventeenth century was Dr. Compton, Bishop of London from 1675 to 1713. Ray has a chapter on the rare trees and shrubs he saw in the bishop's garden at Fulham. Among these are enumerated the Tulip Tree, the Magnolia, the Sassafras, the Hickory, the Box, Elder, &c. Evelyn, who lived in this century, had four large, round, and smoothly clipped plants of the Phillyrea on naked stems, and a hedge of Holly 400 feet long, 9 feet high, and 5 feet wide, of which he was very proud, and mentions it more than once in his writings. This was at Says Court, Deptford, and the hedge was ruined by Peter the Great when he resided there, the erratic Czar having caused himself to be wheeled through it in a wheelbarrow! But Evelyn cared more to promote the planting of valuable indigenous trees than to introduce foreign ones. In this century botanic gardens began to be established, which were the means of introducing many valuable trees; and there is a tradition that about 1670 Dr. Uvedale, the Master of Enfield Grammar School, commissioned one of his scholars who travelled to bring a plant of the Cedar of Lebanon from Mount Lebanon, and that he brought the one which is either standing there now or was standing of late years.

The Cedar of Lebanon was introduced into Scotland in 1683, the same year in which it was planted by Bishop Compton at Fulham and in the Chelsea Botanic Garden. The total number of woody plants introduced during the seventeenth century appears to have been upwards of 130. In the eighteenth century five hundred hardy trees and shrubs were introduced from abroad; 108 being from Europe, three hundred from North America, three from Chili, thirteen from China, six

from Japan, two from the Cape of Good Hope, thirty-three from Siberia, two from Tartary, one from Egypt, two from Morocco, one from Aleppo, one from Barbary, and the remaining few chiefly from Asia. At this time private enterprise became enlisted in the cause, and this fact, together with the formation of public gardens, the curators of which were ever on the look-out for new specimens, deprives the subject of some of its interest. By these means, principally, ninety-four trees and shrubs were introduced from 1801 to 1810 inclusive; from 1811 to 1820, 374; and from 1821 to 1830, 318. To the intelligence and zeal of our nurserymen we owe very much, and their thorough knowledge of the best treatment of trees is probably not to be surpassed by the arborists of any country. But from the date of the general establishment of such businesses, and of botanic gardens, it becomes a matter of extreme difficulty to ascertain when any particular tree was introduced, nor is it a matter on which much interest would be felt; but it is different when we deal with the records of centuries ago, when Bishop Compton laboured in his nurseries at Fulham, when Petticoat Lane was perfumed every spring with Hawthorn blossom, and you might have gathered Violets where you can now only find old clothes; or when Gerard studied the treatment of foreign trees in his Holborn garden, and the Czar Peter rode in a wheelbarrow through Evelyn's Holly hedge.—(*Journal of Forestry*.)

WORK FOR THE WEEK.

KITCHEN GARDEN.

Sow Lettuces for autumn and early winter use and to lift for protecting in frames. The best for this sowing are Neapolitan and All the Year Round Cabbage sorts; Hicks' Hardy White and Bath or Brown Sugarloaf Cos varieties. They should be sown in firm ground to induce firm close growth, as, if the autumn be wet, they form flabby leaves without much heart when sown in or transplanted to open rich soil. Plant without delay the Michaelmas crop of Cauliflowers. If any Celery for late spring use remain to be planted get it out at once; earth-up the early crops as they advance and make sure that there is sufficient moisture at the roots, as after earthing it is difficult to afford water to benefit them. A sowing of Chervil made now will stand for late use without running, and Corn Salad will afford a supply for the autumn and best part of the winter. Continue to plant with Broccoli, Savoy, Borecole, &c., all vacant ground as it is cleared of Peas, Potatoes, &c. Discarded Strawberry plantations may be at once planted with Dwarf Savoy and Coleworts at 12 to 15 inches distance apart. In light soils no digging will be necessary, the plants growing more sturdy and forming better hearts in firm than in loose soil. Sow Endive for transplanting to the foot of walls in September. Do not neglect to sow a moderate breadth of Spinach and Radishes every fortnight, as these crops come in quickly and soon become past use. To have tender sweet Radishes in hot weather water must be given frequently and copiously. The earlier kinds of autumn-sown Onions, Garlic, and Shallots should be taken up as they cease growth, spreading the bulbs over the ground for a few days so that they may be well dried before taking them in. The Garlic and Shallots should be bunched and suspended in a cool dry shed. Potatoes are lifting well and for the most part in good condition, though we hear of a few cases of disease, which happily are not numerous and very limited in extent. Early kinds in some localities are sufficiently ripe to take up and store. This should be done so soon as the tubers are full-sized and the skins set so as not to be displaced by rubbing, and if for use should be kept from light in a cool rather dry place; but if for seed place thinly on shelves in a well-ventilated dry shed. In case of disease infesting the haulm take up the crop at once before it attacks the tubers.

HARDY FRUIT GARDEN.

Apricots are approaching ripening, and although not a heavy crop the fruit is fine. When the fruit commences ripening attention must be given to prevent its being injured by ants, which take a fancy to the first ripe portion, and commit such havoc as to cause its speedy decay. Guano strewed in their runs and over their nests will cause them to migrate, but the best remedy is to put honey and water to the depth of an inch in jars placed at the foot of the wall when the fruit commences ripening, and the ants will drown themselves. Woodlice also are troublesome. They are trapped readily in small pots containing portions of boiled potato wrapped loosely in a little hay and placed in the forks of the branches and at the base of the walls. Earwigs may be trapped in pieces of beanstalk cut into lengths of about 6 inches and inserted among the branches; they should be examined every morning, and any insects concealed therein blown into a pail of water. Nor is the fruit exempt from the attacks of snails and slugs. Search may be made for them with a lantern after dark, or baits of brewers' grains may be laid at the foot of a wall and seen to early in the morning. Wasps should be trapped in soda water bottles about half filled with sweetened ale and suspended in the

trees. Birds may be kept at bay by nets, but unless the weather be unusually dry they will not cause much trouble.

Peaches, Nectarines, and Plums are upon the whole good crops. The fruit promises to be fine, and should be assisted in swelling-off by copious supplies of water, mulching with short manure. In the case of weakly trees carrying heavy crops of fruit weak liquid manure should be given, and the fruit more severely thinned than that of vigorous trees. Red spider is showing itself upon the Peach and Nectarine trees, and should be promptly met by thoroughly syringing with the garden engine in the evening. In case of a severe attack syringe thoroughly with a solution of soft soap, 3 ozs. to the gallon of water. The most forward fruit of Apricots, Peaches, &c., will require attention in turning the leaves aside, but avoid cutting them off, or only that part of them overhanging the fruit, leaving a portion of each leaf so that the buds at the base may mature.

In the late houses thorough syringings must be given morning and afternoon, and the inside borders must be well attended to with water; in a dry period the outside borders should be well watered and mulched. Some liquid manure will help to swell the fruit to the largest size. Netting should be placed below the trees so as to catch and prevent bruising any fruit that may fall from ripeness. The shoots must be kept tied-in, any intended for bearing next season (except extensions) should be stopped at 10 to 12 inches, and any laterals at the first leaf. The earliest-forced house will require to be kept as cool and airy as possible with a view to arrest premature growth, to which Peach and Nectarine trees are peculiarly liable when forced year after year successively.

Apricots and the early kinds of Peach, Nectarine, and Plum must not be syringed after they commence ripening, but there must not be any deficiency of water at the roots or the successional fruit will not swell off well nor ripen perfectly, besides impairing the development of the buds for future bearing. Those swelling the fruit must be supplied with abundance of water, whether in pots or planted out, renewing the surface dressings and affording weak liquid manure occasionally. Syringe overhead in the afternoon at about five o'clock, closing the house at that time unless very bright, when closing may be deferred until six o'clock, admitting air at the last-named hour in the morning if bright, or somewhat later; the weather regulates these matters. Stop strong shoots, and rub off superfluous, admitting light and air freely to the fruit to give it colour and flavour. Look frequently over the various kinds of fruit trees trained to walls or otherwise, nailing or tying-in leading shoots, and removing or stopping those which are superfluous.

FRUIT HOUSES.

Vines.—The Vines in the earliest-forced house will now require a dry atmosphere to thoroughly ripen the wood, but it will not be necessary to employ artificial heat to secure the requisite warmth. All laterals and late growths must be kept well in hand, and complete rest afforded by keeping the border cool and dry. To do this cover the outside border with dry bracken and withhold water from the inside. Young Vines of this year's planting should be allowed to ramble at will provided the light is not too much obstructed. Nothing is gained by crowding the foliage of young Vines, which have to be cut back to three or four eyes at the winter pruning; whilst any that are to afford fruit next season should have the laterals pinched back rather closely to a length of 6 or 7 feet, above which the laterals may have more latitude, as they will aid in the production of roots. Vines in pots for next season's fruiting will have completed their growth and cannot have too much light. The watering should be no greater than to keep the leaves fresh. Keeping too dry will induce premature ripening, and over-watering only tends to continued growth; whereas the object should be to thoroughly plump the eyes and mature the growth. Grapes will by this time have been thinned carefully, and if grown in pots should have the benefit of liquid manure, the pots well supplied with water and the surface mulched with rich material, so that the berries may swell to a good size. Keep the shoots well stopped to concentrate the juices upon the principal foliage and fruit, but any weakly Vines may have growth encouraged, as it promotes increased root-action. Avoid overcrowding. Those trained over the pathway should be kept well stopped, so that the fruit trees may not be too much shaded. Grapes in the intermediate houses will be colouring, and should have a thorough supply of water to the roots after sprinkling the border with guano or soot, which is nearly as rich in ammonia as many manures. Admit air very freely whenever the weather permits, and maintain a night temperature of 70°, and 5° higher by day as a minimum or from fire heat. Late Grapes should have a minimum temperature night and day of 70°, and if air be freely admitted by day scalding will be next to unknown; even Lady Downe's does not scald when the above precautions are taken in time. Ripe Grapes should be frequently looked over, removing any shanked or decayed berries. Keep the atmosphere dry and airy and as cool as possible. Ripe black Grapes will not keep colour long unless the foliage is good, but thin shade during very bright sun will assist in preserving the colour and bloom.

Orchard House.—As soon as the fruit is gathered Cherry trees in pots should be removed to a sunny sheltered situation in the

open air, to insure the thorough ripening of the wood and perfecting of the fruit spurs for next season. If there be any traces of insects thorough syringings must be given so as to cleanse the trees of red spider, and if there be any black fly dip the shoots or syringe with diluted tobacco juice. It is important that the foliage be maintained in a healthy state some time longer. Fig trees in pots should have plenty of water whilst the fruit is swelling, as if there be any deficiency of moisture a check will be given which will cause the fruit to drop off. Syringing must be continued to keep the foliage free from red spider, but must cease as the fruit shows symptoms of ripening, or it will be spoiled in appearance and flavour. The young shoots may still be stopped. A second crop of Figs cannot be depended on in unheated orchard houses, but if a late crop of this delicious fruit be wanted none are more calculated to furnish it than trees that have perfected a first crop in the orchard house and are in good condition. The shoots, having been stopped, will show a second crop plentifully. The foliage being clean and healthy, they may, as soon as the fruit is gathered, be removed into a light airy house, where they can have the benefit of artificial heat, in which they will afford a crop of fruit little inferior in size and quite equal in flavour to the first crop. Pyramid and bush Apple and Pear trees are making much wood and should be restrained by stopping. Raspberries have been excellent and in some places are so still. As the crop is gathered the bearing canes should be all cut out, and the young ones thinned to about six to each stool so that sun and air may have free access to them, thus securing the ripening of the wood and buds. Autumnal kinds should be well watered and mulched, and secured to stakes if necessary. Do not neglect to pot runners of Strawberries as they may be had, for there is yet time to layer them in pots for forming new plantations. Well-rooted plants put out from now to early September will afford a nice crop of fruit next season. Forced plants which were put out in May and early June should have abundant watering and be mulched with stable litter, and they will fruit abundantly in late summer. Any Currants or Gooseberries required to be kept late should be covered with hexagon netting, which is better than mats. Those fortunate enough to have these fruits against low walls will have no difficulty in keeping the fruit until a late period, protection being afforded against birds and wasps.

PLANT HOUSES.

Greenhouse.—The varieties of *Lilium speciosum* (lancifolium) should have the stems tied so as to admit plenty of light and air to the foliage. Look well after aphides and dust with tobacco powder or syringe with tobacco water, washing well off the following morning. Afford a top-dressing of old cow dung or well-rotted manure and a liberal supply of weak liquid manure; over-watering is equally injurious to the roots as a deficiency is to the foliage, which, if the soil get very dry, is sure to cause the falling-off of the lower leaves. These with plants of *L. auratum* coming on for late flowering should be plunged in ashes in an open sheltered situation, well staked and secured to prevent the stems being broken by winds, and removed to the greenhouse when advanced for flowering. Plants of *Lilium* that have done flowering should be placed out of doors and be well attended to with water with a view to the plumping of the bulbs, upon which depends next year's flowering. Early-flowered *Pelargoniums* should at once be placed outdoors in the full sun, affording no more water than to prevent flagging, with a view to the thorough ripening of the wood before cutting down. If likely to become too wet from rains lay the pots on their sides. *Chrysanthemums* must be attended to in staking and tying-up the shoots as they advance in growth, for if this be neglected they are liable to be broken by wind. Early-flowering *Heaths* will have completed their growth and should be placed outdoors upon a bed of ashes sufficiently thick to exclude worms. Afford them a position where they will be protected from bright sun at midday, but the shade must be of a light description, as too much shading is injurious, and after a week it may be dispensed with, as thorough exposure will cause the hardening of the wood and setting of the bloom. The plants should be examined at least once a day for water, and any requiring a supply be afforded it plentifully, regulating it by the strength of the plants, the freer-growing requiring more copious supplies than those less free in growth. *Camellias* that flowered late should have every encouragement to make a good growth by maintaining a moist atmosphere and affording copious supplies of weak liquid manure, especially to weakly plants. Those that have set the buds should be kept cool, either by placing outdoors in a position shaded from bright sun, or in a house that admits of very free ventilation. This is much the more preferable method, as, if the weather be very wet, the soil becomes soddened, the roots perish, and the buds turn brown and drop.

Now that structures of this kind may have the plants placed outdoors in sheltered situations, an excellent opportunity is afforded of giving them a thorough cleaning, the required repairs being made and the woodwork thoroughly painted. Work of this kind is much better done at this time of year than at times when the plants must remain wholly, or in part, inside the house, which entails much needless labour and after-injury to the plants. Plants

not only look better, but grow better, in a clean house than a dirty one.

TO CORRESPONDENTS.

. All correspondence should be directed either to "The Editors," or to "The Publisher." Letters addressed to Mr. Johnson or Dr. Hogg often remain unopened unavoidably. We request that no one will write privately to any of our correspondents, as doing so subjects them to unjustifiable trouble and expense.

Correspondents should not mix up on the same sheet questions relating to Gardening and those on Poultry and Bee subjects, and should never send more than two or three questions at once. All articles intended for insertion should be written on one side of the paper only. We cannot reply to questions through the post.

A DAY IN THE COUNTRY.—"Last year some of your readers were led generously to help us to provide for nearly five hundred poor boys and girls who attend the Hackney Juvenile Mission a day's excursion into the country. This year the Manager hopes to be able to take some three hundred children for a day in July or August, and I should be glad if your readers will again aid practically by sending donations to either Mr. John Newman, Hon. Manager, 117, Cheapside, E.C.; Mr. H. M. Heath, 4, St. Thomas's Road, Hackney; or to Athro Alfred Knight, 71, King Edward's Road, South Hackney, London, E."

FOXGLOVE (Mrs. D.).—Sperts are common in Foxgloves, but are not permanent. The white variety is very usual.

VEGETABLE MARROWS (Tryng).—Very varying temperature probably causes the decay.

PEARS (J. E.).—Any of the leading nurserymen could obtain them for you.

MOLES (C. J.).—We cannot guess how the moles got into the cistern. They could creep up a pipe 2 inches in diameter. Put a piece of wire net over its mouth.

GRAPES NOT COLOURING (W. Pantry).—No wonder. Half the number of bunches would be a good crop.

TREATMENT OF NEGLECTED FUCHSIAS, &c. (Paddle).—Prune your Fuchsias and replot immediately, syringe them freely two or three times daily, and they will soon put forth fresh growth. Repot the Ferns immediately, but do not disturb the Cyclamens planted in the open ground till the end of September, then take up and replot, retaining a little soil about the roots and using pots of a size proportionate to that of the plants. Lift your Potatoes as soon as the tubers have ceased swelling. If any are diseased spread the whole out thinly in a dark airy room, and examine them every few days.

TRANSPLANTING OLD CURRANT BUSHES (E.).—With a due exercise of care in saving as many roots as possible, and retaining a slight ball of soil with the roots, your old Gooseberry and Currant bushes may be transplanted advantageously and successfully.

SUCCESSIONAL SORTS OF STRAWBERRIES (Idem).—La Marguerite, President, Dr. Hogg, and Frogmore Late Pine, are four good sorts ripening in the order in which they are named.

SUMMER PRUNING FRUIT TREES (Idem).—Read our reply to "E. H. R." in this issue, also prune the leading shoots simultaneously with the side shoots. The same system of pruning applies to all kinds of Apples, Pears, Plums, and Cherries, whatever may be their peculiar habit of growth. Do not forget, however, that some sorts require much greater care in training than others, each tree affording a clear indication of its peculiar requirements.

ROSE TREE LEAVES INSECT-EATEN (X. L.).—The semicircular pieces are eaten by the Leaf-cutter Bee. There are drawings and descriptions in "The Gardeners' Magazine of Botany." Its scientific name is *Lyda inanita*. The fly hovers over the Roses, and may at once be identified by its glossy yellow wings.

PLANTING ROSES, SHRUBS, &c. (Sambo).—November is the best month for planting Roses; Roses in pots may, however, be planted at any time. If you transplant shrubs in August, remember that due attention must be given to watering; much better would it be to wait till September, and so save much labour. Pansies, Pinks, and Carnations may all be transplanted in August if they are well watered regularly afterwards. Lilies may also be moved then if the flowering is over. For the flower beds which you purpose making in that month take such spring flowers as *Myosotis*, *Aubrietia*, *Silene*, *Saponaria*, *Viola*, *Limnantes* to clothe the surface with greenery during winter, and to afford a brilliant display of bloom in spring. Or you may make pretty beds of hardy succulents, dotting them with such bulbs as *Crocuses*, *Snowdrops*, *Tulips*, and *Hyacinths*.

STRAWBERRIES FOR A LONG SUCCESSION (M. D. D.).—Black Prince, La Marguerite, Pioneer, La Grosse Sucrée, Vicomtesse Hericart de Thury, President, James Veitch, Dr. Hogg, Sir Charles Napier, Frogmore Late Pine, Elton Pine, and Helene Gloed.

RAISING AUCUBAS FROM SEED (G. Todd).—March is the best month for sowing, or for a general rule sow the seed as soon as gathered. No particular treatment is required; it usually vegetates freely in a greenhouse, and if due care is exercised in watering your seed will no doubt germinate very soon.

SUMMER PRUNING FRUIT TREES (E. H. R.).—Pear and Plum trees should be pruned twice during the season of growth. The first time after the spring growth is some 9 inches or a foot in length, and again at mid-summer; after which let the shoots grow, and early in September twist each shoot round immediately beyond the third or fourth eye from its base, turning the end downwards. By this process the bottom buds become plump and full without starting into growth, some sap still finding its way among the bruised tissues of the "twist," which is cut off with the turned-down shoots as the leaves fall.

MELONS SPLITTING (Hampshire).—The cracking of your Melons was probably caused by watering after the fruit had ceased swelling. In future when the fruit begins changing colour gradually reduce the quantity of water, giving very little and that only around the sides of the box or pit wall. Cracked fruit is also attributable to careless watering, such as letting

the soil become too dry before the fruit is full grown, and then again making it very wet, thereby inducing such a strong flow of sap as causes the fruit to crack.

GREENHOUSE ASPECT (T. K.).—Presuming that the south end of the greenhouse will be glazed from about 3 feet from the ground to the roof, we should not hesitate to erect the house in the position you propose—i.e., facing the east. An accidental transposition of words occurred in the answer you have quoted.

MILDEW ON GRAPES (F. H.).—Do not remove the sulphur till the Grapes are ripe. It is only then that you can be assured that all danger from mildew is past. You must sprinkle the sulphur on the leaves as well as the fruit.

WHITE GLOXINIA (J. G.).—The flower is good and worthy of a name, yet is not equal to such varieties as *Avalanche*, *Boule de Neige*, and *Mont Blanc*.

GRAPES SCALDED (Clare Subscriber).—Your Vines, judging by the leaf sent, are extremely healthy. The "disease" we think is the scald. A little fire heat at night and a rather dry atmosphere, together with ventilation early in the morning, is the only mode that we can suggest for arresting the injury. There are varieties of Black Hamburg slightly differing from each other. Both your Grapes are Black Hamburgs. Your letter shall have our further attention.

VINES INJURED BY SULPHUR (Leafless).—Encourage your Vines to make a second growth by syringing them and providing a warm moist atmosphere. The growth made, if the autumn prove favourable, may still have time to become matured. Your Orange trees require fresh soil, rich turfy loam, and to be placed in heat, and syringed freely to encourage growth. Keep the foliage clean and free from insects.

NAMES OF PLANTS (Tyro).—The Begonias are all florists' varieties. (*Begonia*).—Specimens must be sent to our office, and not more than six at a time. (*Ramamo*).—*Galea orientalis*. (*G. B.*).—*Deutzia scabra*. (*A. G.*).—Specimens insufficient; 6, *Achillea Millefolium*. (*A. H. Sh.*).—Orchids too much shrivelled; 2, *Brassavola* sp. (*J. S. M.*).—*Galea officinalis*. (*T. Wrighton*).—*Epipactis palustris*. (*Peat*).—The fronds are not in fruit. (*G. W. J.*).—We cannot determine *Ceanothus* from a scrap. (*W. M.*).—*Clethra* sp. (*E. H.*).—1, *Pentstemon* sp.; 2, *Monarda didyma*; 3, *Thalictrum* sp.; 4, *Melittis melissophyllum*. (*C. South*).—3 and 4, *Lastrea Filix-mas*. Send the others again in fruit. (*Miss Barron*).—*Philadelphus* sp.? (*G. N. V.*).—*Erythraea Centaureum*. (*A. Z.*).—1, *Begonia Dregei*; 2, *B. Ingrami*. (*B. E. Wake*).—*Mathiola incana*. (*A. F. Pemberton*).—*Epipactis latifolia*, a fine specimen.

THE HOME FARM:

POULTRY, PIGEON, AND BEE CHRONICLE.

CULTIVATION OF TURNIPS.

THE cultivation for common turnips is somewhat different from the preparation of land for Swedish turnips, because the use of artificial manures is now general, and it is seldom a long fallow is required except upon strong lands very much out of condition and foul with couch grass, &c. It sometimes happens, however, that strong heavy soils are sown with early turnips to be fed off with sheep during the months of August and September, in which case the land should be treated precisely in the same way as directed and recommended in our late article on the cultivation for Swedish turnips, taking care if possible in all cases to till the land in the previous autumn on the surface, and then to plough it up deep or make it into stretches, in order that it may lie high and dry during the winter months. It is only by this means that the full effects of spring tillage can be obtained, especially in seasons like the past, when the whole of the month of May was unfavourable for the tillage of strong land in consequence of the succession of heavy rains. After autumn tillage the land will seldom require much spring working, and ploughing should be avoided, especially as it is of great importance to retain the weather-beaten surface. To have the full advantage of this we prefer to scarify only, and then to drill with manure in the usual way about the 20th of May. The turnips will then be sufficiently forward to be fed off on the land before the setting-in of the autumn rains, which is so desirable in obtaining a good seed time for the wheat crop which is to follow. As the far greater portion of the turnips grown on light and friable soils are now taken as a second crop after rye, trifolium, vetches, and sometimes after trefoil and Italian rye grass cut for hay, it becomes a question almost entirely of the state of the land as regards cleanliness in the autumn before sowing the fodder crops, as there is no time to clean the land successfully after the crops are cut up or fed off without so much delay as to risk the turnip crop. In many seasons if it is attempted to plough the land several times, with the consequent harrowings and rollings, the precious moisture required to vegetate the turnip seed is often lost, and with it the prospect of a full crop of

roots. It is therefore desirable to select those fields which are the cleanest for sowing with any of the fodder crops, and it is best, especially with land intended for trifolium, to have the bunches or lumps of couch or onion grass forked out by hand, as this will take less time and be done at far less cost than ploughing, and without delaying the seed time. Whether the land is intended for trifolium or other fodder crops it is a good plan to fork out the grass, because when ever so little quantity of couch grass is ploughed-in it will increase, especially where the land is in good heart and condition, to a great extent during the early spring months, and probably delay the seed time, and sometimes destroy the prospect of a turnip crop—in fact it may be accepted as a rule in agriculture that the first cost of removing couch from the land will be the least, cost what it may. After the removal of a green crop the tillage should commence immediately, every day being of the utmost consequence, either by very shallow scarifying or rafter-ploughing, harrowing, rolling, &c., to remove any weeds or haulm of green crops which may be left, because the burying of these substances is inimical to the growth of roots by making the land too light and hollow, and in their decay fermentation takes place, a blue mould is formed containing injurious acids extremely detrimental to the successful culture of turnips, and is often the proximate cause of club root, or "finger-and-toe" as it is called, upon land where it is deficient in chalk and lime. Although we are strongly opposed to the burning of couch or weeds, preferring to rot them as a dressing for pasture land, yet we find that substances of some kind are required to mix with artificial manures, whether of superphosphate, guano, or others; and we recommend, especially upon sandy or loamy soils, a mixture of screened chalk made perfectly fine and prepared in the winter months or early spring, in order that it may be quite dry and run freely with the manure from the drill. In districts far removed from chalk it is a good plan where town dung and refuse ashes are available to have these screened for use, as they not only serve to mix with the manure in order to its better distribution, but we have seen that it acts to some extent like chalk, and greatly encourages the growth of turnips in the early stages of growth.

In selecting a drill for the home farm we recommend a one-horse drill, which will drill two rows at once at 2 feet apart, or three rows at 18 inches apart. After using this kind of drill for nearly thirty years we have found its advantage, especially upon hilly land, not only because it is light of draught, but it may be worked by one horse as fast as the land is ploughed without dividing the labour of other horses. Now this to our mind is a matter of prime importance in turnip cultivation, particularly after green crops, because it very often happens that in waiting for the large heavy drill the land gets too wet or too dry, according to the weather, and the season is never so surely obtained as drilling day by day as fast as the land is ready, and nothing contributes practically to the attainment of this object so well as the use of the one-horse drill. For some years the water drill had some advocates, but it seems now to have gone out of use. The difficulty of obtaining and carting water in the hill districts appears to have entailed too much labour, and also loss of time. In the use of artificial manures for turnips, if the green crops have been fed off by sheep, 3 cwt. per acre of bone superphosphate with ashes or other matters will prove sufficient to produce a full crop of turnips, particularly if the sheep received cake or corn with the green food; but in case the fodder crop has been used for feeding horses, cattle, &c., at the farmstead, as is often the case on a well-conducted home farm, then more manure should be applied with the drill, and 3 cwt. of superphosphate with 1½ cwt. of Peruvian guano is not too much, and will generally produce a full crop.

The kind of seed is a matter of importance, particularly if the crop is intended to remain in the ground during the winter months, and if we look at the seedsmen's list of sorts a novice may be entirely bewildered in making his selection, and it will certainly depend upon the period and purpose for which the roots are required for use. The Scotch Yellow being a hybrid variety

are useful to stand the winter, and are very quick of growth, and will prove a partial substitute in case of a failure of the Swedish turnip. But for early feeding in the autumn or winter, parties often select the White Pomeranian, White Tankard, or Green Globe, but we have found that either of these sorts if sown early will not keep, and if not rotten they lose their feeding properties very quickly. We therefore recommend, as the result of our own experience, the Greystone or Red Mammoth sorts, as we find they do well both for early or late sowing, they grow quickly, they keep sound, and are very forcing for stock. When turnips are sown very early they require as much room in growing as Swedes, and they often produce as much weight per acre, and may therefore be drilled at 2 feet between the rows. For later and winter feeding we think 18 inches the best distance. The time of sowing will of course vary according to circumstances, more especially as a second crop, but the best time for sowing the main crop for winter and early spring feeding is from the 1st to the 20th of July. The quantity of seed is of great consequence, and we recommend not less than 3 lbs. per acre, not only on account of the enemies to the young plants, but also because a thick plant always grows quickest and comes earlier to the hoe, also when the plants are thick and regular they may be set out by the hoeing machine, or by horse-hoeing across the rows; and where hand labour is scarce, and when the hoeing is required in the busy time of harvest these methods of hoeing will save the crop from serious damage, and the hand-hoeing may be delayed until the hoers are at liberty. It will be noticed that we have recommended a portion of guano as manure for late turnips, although it will be found in our article relating to Swedish turnips, we objected to its use. This, however, is to be explained by reason of the Swedish turnips having come to maturity, and also being required to be kept afterwards, whereas in late turnips they are not often arrived at maturity before being used as food for stock, and have, therefore, no time to decay or lose their value. There is no doubt that the light soils are best adapted for the growth of common turnips, not only because they grow more quickly after the autumn rains commence, but also because they can be fed-off with sheep upon the land without either injury to the animals or the succeeding crops. We have on this occasion not made any remarks upon the latest period at which turnips can be sown and grown, as we hope to treat of this matter in another article at a future time, and more especially as relates to the growth of stubble turnips, as well as those sown at a late period with varying preparations and different objects in view.

WORK ON THE HOME FARM.

Horse Labour.—The horse-hoeing of Swedes and early turnips must be continued, for we have just passed a season almost unparalleled for the production of weeds, and nearly everywhere are to be seen the weeds in advance of the work of destroying them. The cultivation for and drilling of turnips after green crops is still in progress, and in a few days the forwardest of the crops of peas and winter oats and also white Canadian oats, rye, &c., will be ready for carting to stack; in fact, we have seen a sample of new fresh-thrashed oats of the Canadian sort, and as we are now so close upon the general harvest for cereals of all kinds in the earliest districts, it will be well to anticipate the period, and be so prepared that all the horse labour as well as manual labour may be ready at the time required. There are many ways in which these matters may be forwarded beforehand—by drawing straw and reeds for thatching, making spars, &c., also carting faggots for making rick-stands, for it is seldom now that much corn is stacked in the rick yard as it used to be, because the ricks being made in or near the fields where the corn is produced, saves horse labour and saves time also, so necessary in securing the grain when it is once in order.

Hand Labour.—We have often known farmers who have deferred cutting corn at the proper time, saying they had other work to be done for a few days before they could commence harvest, and this is oftentimes the prelude to losses in various ways. If the corn is over-ripe the grain becomes poor and weak, fetching a lower price in consequence, and in exposed situations we have known very serious loss by the grain being whipped out by wind. The early cutting of grain not only gives the best sample, but when cut and set up in shock, if it takes heavy rains it will not sprout so quickly. The quickset and all other clipped hedges should now be finished trimming, the sooner the better. We see also that a hedge-trimming machine has been exhibited at the Royal Agricultural Society's Meeting at Bristol, and was approved by the Judges. This is a step in the right direction, and will save labour at the busiest period of the year. As fast as peas are cut the women can move them on to the half the land, which will assist in drying them, and also enable the horses to plough half the land, and if required it may be sown daily with turnips, mustard, rape, and such-like crops, and when sown the peas if not dry enough for carting may be moved on to the other half of the land, and thus enable the whole of the field to be seeded or ploughed before carting the crop of peas. A few days of horse labour at that time are very important, because when harvest carting of corn is once begun there is little time for other work until it is finished. The shepherds now will be very busy on all farms

where sheep are kept, whether they are breeding flocks or sheep bought in for winter grazing. The draughts of off-going ewes and also of the wether lambs are now being made for sale; all these require careful selection as well as trimming to improve their appearance at the fair, or when sold at any time. In the grazing flocks which are now being bought for the winter feeding of roots on the land, also grazing on the stubbles and pasture land, if the purchases consist of lambs, especially if they are in good condition and well clothed with wool, it is an excellent and profitable plan to shear the lambs at any time up to the 14th of August, as they not only cut a valuable fleece if they are properly washed, but it will be found that all the wool will be gained, and if sold fat in February or March following, the animals will be worth from 5s. to 7s. each more than similar animals not shorn. This is accounted for by the animals being more comfortable during the winter months, the wool being shorter and more impervious to rain or snow. When lambs are winter-fed without being shorn the wool opens along their backs, lying down on either side. This allows the wet to fall on the skin and trickle down the sides of the animals to their great discomfort. This process of shearing is now facilitated by the use of a shearing machine which we have seen, and it is an ingenious invention by which a large number can be shorn in one day.

DARK AND LIGHT BRAHMAS IN COMPETITION FOR CUPS.

I SHALL be obliged by your inserting a few lines on the above subject to call the attention of committees of shows to the unfairness of giving cups between Light and Dark Brahmas; as the Darks are naturally the larger birds of the two the cups almost invariably go to them. I think exhibitors of both classes ought to be placed on the same footing. I have taken a good many cups, but never won when it was between the Lights and Darks. I was awarded one for my Light Brahma hen at Dunmow and Mr. Lingwood for his Dark Brahma, but as there was only one cup between the two classes the Committee gave it to him, although in catalogue it stated I had the cup awarded me. I have written to the Secretary, but have had no reply. In the report of the Boston Show it is stated the Lights as a class were the best, yet the cup went to the Darks. I should suggest that cups be done away with, making the prizes equal.—PHILIP HAINES, *Palgrave, Diss.*

CLECKHEATON POULTRY SHOW.

THE tenth annual Show was held at Cleckheaton on Saturday last, when one of the hottest days of the season contributed to the tenth success of the Society, there not having been a single unfavourable day as regards the weather, and as usual the gathering was very large. The arrangements were very good for an open-air show, but so terrific was the heat that one fowl and one Rabbit died, and many others had to be bathed with water to prevent them dying also; but the attention of the stewards was unremitting, and many of the birds were placed in their hampers to prevent other fatalities.

Game headed the list, but many of the birds were very ragged, although some were good. **Dorkings** a very good lot, as also the **Cochins**, the first and second of which were capital Buffs, and third Partridge. **Spanish**.—First a grand even pen, second the pen containing the doubtful hen, and third a fair pair. In **Brahmas** the two winning pens were very good Darks. **Hamburghs** had but three classes, but they were about the best section of the poultry. **Game Bantams** were good, but a little shabby in feather. In any other Bantams, first was a most lovely pair of Whites, perhaps the best in the fancy; second and third Blacks. In chickens a handsome pen of Buff Cochins were first; second very good Light Brahmas; and third Darks, and the class a very good one. **Ducks** were very good in all classes.

Of **Pigeons** Carriers were first, the winners being Duns, both cocks and very good. Pouters, first a Red cock in grand form, second a Black, better but rather flat. Tumblers, the Birmingham cracks alone, the hen first and cock second. Fantails very good; a beautiful Squeaker was first. Dragons all noticed, the winners Blues. Jacobs, first Red and second Black. Turbits, first a Blue Spikehead, and second what is now rare, a good Shellcrown. Owls, first White African and second a Blue English. Antwerps were very good indeed in both classes, especially the winning Short-faced Dun.

Rabbits had only four classes. First in Lops was the well-known Fawn doe from Blackburn, second a grand Fawn-and-white doe, also very good. Himalayan and Angora were not a good class; the new French-Grey Angora first and a fair White one second. In Silver-Greys there were only five, but all were good and of the most correct shade. In the Variety class first was a good Silver-cream, second a Silver-blue Dutch well marked, and very highly commended a correct Silver-cream, but a little moulty.

HEN COOP.

We are not surprised that your ("T. F.") chickens do not thrive in the coop you describe. We recommend you to adopt the fol-

Fig. 11.—Part A is divided off from the rest of the coop by a partition, with a hole large enough for the hen to come in and out at pleasure. Part B is not divided off, and is only to put the food behind.

huge cannon, one of the very big guns of the world. Go down the Thames to a certain arsenal, and there you will find a great number of them, and they are called in playful fondness "Woolwich infants." This is English fun. The first fancier who had a very large Pigeon said to his visitors, "Now I want to show you a little Runt of a Pigeon I have imported or bred," and forthwith surprised them by throwing open the door of his loft and pointing in triumph to a very big bird, which big bird in time, from mockery or fun, took the name of Runt. This is my explanation. I am quite aware that learned people say the word Runt comes from the Italian *Tronfo*, in answer to which I say, Pooh, pooh! And being also learned I reply, Runt comes from the Dutch word "rond." Having now squared matters with my ideal learned opponent I go on comforted. That very large Pigeons in England called Runts came and come from the shores of the Mediterranean I believe—yes, and from India too; but Runt is a very old English word, and for fun a big Pigeon was first nicknamed a Runt, and then the name stuck to it. This is my solution of the difficulty.

I spoke of the contrast between Pouters and Tumblers, and that each was benefited by the contrast, one looking much better by the side of the other. Just as in one way Pouters and Tumblers are perfect contrasts, so are Pouters and Runts; but they are also alike, thus Pouters and Runts are the longest-bodied Pigeons and the longest-feathered Pigeons—that means that the flight feathers and tail feathers are the longest. Here ends the similarity. Now for the contrast. Pouters longest legs, Runts among the shortest; Pouters very slender, Runts very thickly built; Pouters perpendicular Pigeons, standing up, looking around—Runts horizontal Pigeons, with eyes to the earth; the one high up in the world, the other low down; one a noisy strong flier for a short distance, and active too—the other not wishing to fly at all, but, like fat heavy people, not liking exercise of any sort. Yet these two Pigeons are near relations. I have seen a great many Pouters, first cousins once removed to the thick short-legged Runts—yes, and bred

lowing. The advantage of this coop is that the hen can in rainy weather go into her sleeping house, A, where she is effectually sheltered from the weather, and the food for her and her chickens can be placed behind the door B (which is made to open and shut), and the other fowls cannot get at it, which is the case in other coops; but the coop can thus be left standing in the poultry yard with the other fowls. Besides, the second door, B, is used in cleaning the coop out. There is also a piece of wood which fits to the wire bars in front and reaches three-parts of the way up, so that at night when it is put up the hen is securely shut in, and sufficient space left for ventilation. Another advantage in this coop is, that if suddenly a shower comes on, you can without the least trouble drive the chickens in, push down the two sliding wires, c, and the chickens are in all safe with plenty of room to run about;—the shower over, the bars are pulled up.

PIGEONS—HINTS TO YOUNG AMATEURS.—No. 5.

RUNTS.

WHY are the biggest Pigeons in the world called Runts? Turn to the first dictionary at hand, and you will find the word Runt thus entered and explained:—"Runt, a small stunted animal." Now, there is always a vein of humour in Englishmen, and especially about anything very large. A father of a huge strapping son of 6 feet in his stockings pleases himself to call him "his little boy," and so often introduces him into company. Then there is a

them too. It is the old story of the man got up in the world and become an aristocrat, yet he has poor low relations somewhere. I found a poor man, a very poor man, in a cottage a few years since talking broad Wiltshire; very down in the world he, as his immediate ancestors had also been—a labourer, that's all, yet related distantly to a baronet of an old creation, and when the bart, was made acquainted with the fact he, much to his honour, helped the poor man, who somehow or other had his coat of arms lying by, but scarcely valued at all. So of our humble friend the Runt; he is a cousin of—not a baronet, but my lord Pouter, a very high and mighty gentleman indeed. 'Tis very odd, this relationship between the tallest and the flattest Pigeon—the one nearest to the ground, and the one furthest from it. The uses of the two are equally diverse. The Runt is the bird for the table—the biggest, and fullest, and fleshiest, the most piesome (to coin a word) of all Pigeons; but whoever thought of eating that aristocratic skeleton a Pouter? He carries no flesh—indeed he ought not to have any. "Long and lean" is his cut; his waist is to be, according to fanciers, of wedding ring proportion. Then the Runt, if not too highly or closely bred, is an excellent feeder of its young and nurse for other young; whereas Lady Pouter, like many great ladies, insists on that duty being done by some inferior. She always, as a rule, insists upon a wet nurse for her young ladies and gentlemen.

Next about the varieties of Runts. Some years ago—a good many; I remember several varieties—a huge, very huge, Runt was brought from London by a friend of mine and called a Roman Runt, which tried in vain to fly up from the ground with his other Pigeons. Then there was the Leghorn Runt that cocked up its tail and stuck out its breast, which, after having been lost sight of for long, has re-appeared at our shows under the name of Maltese or Florentine, and quite possibly they came from some Mediterranean port. Then there was the most common of all Runts, which in those days was called the Spanish Runt; plumage

usually white with patches of blue or chequer in its body. This seems to be the Runt of our shows of the present time; but, young amateur, you must understand that the show Runts are few because of the difficulty of breeding them. The giants of the world are few, and we never read of their going about with their gigantic families; but it is quite possible to breed a goodly number of, not show Runts, but still very large Pigeons, which are very fit indeed for food. These papers are written for the benefit of young amateurs, but not necessarily young in years, only in Pigeon knowledge.

I have known Runts find favour among middle-aged people who have retired from business, and who with their garden, friends, and newspaper, and a hobby or two, manage to get on comfortably. A competence made in trade, or an income left them, they take a house with a little garden near a town, and live on in an easy innocent way. The husband has usually a well-filled waistcoat and broad back; in fact he is a Runt in the Pigeon sense, and so takes to Runts. A little shed is big enough, and he may have his birds on the ground floor if no cats are to be feared. Now my comfortable, middle-aged, retired tradesman, at peace with all the world and everything in it save sometimes that last button of that capacious waistcoat of his, likes his dinner. It is a sign of middle age, no doubt it is; so therefore he likes, or would like, the Pigeon which would best supply him with a dinner, and he would like to get his birds as large as he could. Such a man should get hold of some Runts not up to show size, and also cross them with some other strain, picking them up in a bird shop or in the selling class; on no account getting them over-large, for rely upon it, if cheap, they are no breeders or very old. Sometimes at a farm or in some country place a very big Pigeon is to be picked up, a common farmyard Runt as it is called; and the result is, after a little time and some pleasant walks with an object (a great comfort to my retired friend) a nice lot of moderate-sized and good breeding Runts are to be got together, and some well-filled pigeon pies are the result. These birds, not being much of flyers, will not annoy neighbours, but live quietly at home. Really fine large birds walking about have a noble appearance. I own this fancy for Runts is not very high-class, but it is pleasant to be able to add to the family supply of food, in addition to the pleasure of seeing, tending, and mating the birds. They, like most large things, are kindly and do not fight; also tame, for they will let you slip your hand under them and look at egg or young without being angry.

For their quietness and gentleness I have known these medium-sized Runts kept as nurses for young Pouters, and they answer the purpose well, not being pugnacious like Dragons. Their table qualities also render them favourites with their fanciers' wives, and they let their husbands enjoy their Runt fancy in peace, because of the pies to be forthcoming. But mark, I warn all such who intend to breed for table to keep clear of all ideas of Runts of the show size or any approach to it. If such a bird falls in their way cross it with a large common Pigeon, and you will gain greatly by such a cross, as the common Pigeon is the best of all breeders.

The Runt fancier I have imagined may as he goes on get very pretty birds as well as profitable ones. Thus, driving up under the archway of an old-fashioned inn in a midland county I was—it was long since—much delighted to see a whole flock of White Runts quite at home in the square yard. No doubt they were kept for use in the first place, for pigeon-pie is a stock dish at an hotel, always welcome to guests, particularly to travellers from the great City, to whom it smacks of country life and scenes; but the birds must have been selected for the eye as well, as they were all white. I have seen large Birmingham Rollers which would not make a bad cross to get good table Runts; also I have seen the old-fashioned light-coloured Trumpeters that would answer well enough, for they are runtishly built, and any cross would add to the fertility of the Runt, providing at the same time for size. The table supply is, I think, too much neglected in both fancy Pigeons and fancy poultry, but there is no reason it should be. Utility has been much sought for in regard to Homing Pigeons, why not also breed for the table? Certainly the ordinary dovehouse bird is very small, and might easily be made larger by a cross with the Runt. I fear the Silver Runts so generally shown are all related, so I would not match two Silvers, not a pretty colour either, but get other colours, and crossing colours you would get variety, which is always pleasing. Indian corn does well for Runts, and I have seen them eat heartily of barleymeal and water made thick. I am quite sure a good and profitable Pigeon may be bred for the table, giving pleasure to the master and quite satisfying the careful provident housewife.—WILTSHIRE RECTOR.

VARIETIES.

THE harvest is advancing rapidly to maturity, and in the south a few early crops have been cut. In many places the crops are light, but in the well-farmed lands of Essex they are full and fine. In the great agricultural district of Lincolnshire and Yorkshire the grain fields have a splendid appearance. Wheat, barley,

and oats in the fens, and indeed wherever the soil is not light and shallow, give promise of abundant crops. The straw is more luxuriant than we have ever seen it, and the heads appear generally fine. The hay harvest in those districts has proved the best on record, and has been secured in fine condition.

— WE hear there is some chance of the poultry show in connection with the dairy show at the Agricultural Hall being this year on a much more extended scale than heretofore, under the patronage and direction of the Poultry Club.

— WE regret to learn that in some cases where extra prizes were awarded at the Paris Poultry Show they have not been paid in full according to the arrangement made between the French and English Jurymen. Remonstrance has been addressed to the authorities on the subject, and we have reason to know that if redress is not given a protest will be presented to the highest authority on the British Commission.

— OWING to the great heat and protracted drought the young turnip crops in Lincolnshire, where this crop is extensively grown, are suffering considerably. Potatoes, too, are flagging severely, and cannot form tubers for want of rain. This applies to the late crops in fields, early sorts in gardens giving a productive yield. The mangold wurtzel crops, especially those that had been sown early, are looking remarkably well, but rain is urgently needed to carry them on. The pastures are quite burnt up, and trees and hedges are white as a sheet with dust from the limestone roads.

— THE attendance at the Royal Show at Bristol on the last day of the Show numbered 30,012, against 31,935 at Liverpool and 61,567 at Birmingham. For the week the visitors at Bristol were 121,851, against 138,354 at Liverpool and 163,413 at Birmingham. The receipts were: Liverpool, £12,969; Birmingham, £12,485; Bristol, about £10,285. Thus Bristol falls below the two great towns in which the shows of 1876 and 1877 were held, but still gives a large and a profitable return.

— WATER FOR SHEEP.—What an unprofitable mistake it is to suppose that sheep do not require water. We invariably give them the opportunity of settling that question for themselves, and it is surprising to see how much they drink, especially milk-giving ewes, and also all sheep when eating cake, meal, &c., in addition to their green food. I attribute my trifling loss in sheep and lambs to their having constant access to water by means of an iron tank watercart (Croskill's) which I have used for thirty odd years.—J. J. MECHI (in *Mark Lane Express*).

ADVANTAGES OF THE STEWARTON SYSTEM OF SUPERING.

THERE are several obvious advantages in placing empty supers upon the top of those which are already occupied, which have already been pointed out in former numbers of the *Journal of Horticulture* both by "A RENFREWSHIRE BEE-KEEPER" and myself. Upon the old plan of inserting fresh supers between the stock and those previously occupied you have bees constantly making fresh comb immediately over the stock, and the super is always in danger of invasion by the queen, who, if she chances to find her way into it, is almost certain to find empty cells (especially if there has been a check in honey-gathering) which she at once proceeds to fill with eggs. This very rarely occurs upon the Stewarton plan. Stewarton supers are shallow and the combs broad. The bees first begin to construct their combs in the box next to the stock hive, and then gradually extend their operations into the upper chambers, sealing and completing in the first place the lower supers. If a good start has been made you have this immense advantage, that if the queen enters the super, finding all the cells already occupied with honey, she speedily returns into the stock hive, and all future supers are almost absolutely secure from invasion, as the new combs are always constructed in the upper compartments.

My experience is that upon the old plan it was the exception to secure a super perfectly sealed and free from all trace of brood and pollen. With the Stewarton system my supers have been almost invariably free from all impurity; and the honey boxes next the stock, from two to six in number, have been completely sealed, almost to the last cell. As a matter of course the top supers are never completed, as it is always necessary to allow the bees plenty of room in advance of their actual requirements to accommodate the bees and prevent swarming. As the lower supers are completed it is best to remove them, and bring down the pile of boxes in course of progress on to the top of the stock.—J. E. BRISCOE, *Albrighton, Wolverhampton*.

SUFFOCATION OF BEES.

A LADY who calls herself "a bee-wife," has six stock hives and six swarms from them, all in straw hives of an ancient pattern and of rustic appearance, wants to know how she can avoid stifling the bees at the end of the season. We are pleased to tell

this lady that there is something better for her bees than the fumes of sulphur. There is a pleasant and satisfactory way of taking honey without the destruction of bee life. Some young and inexperienced bee-keepers are easily influenced by whims and novelties. Many of them are men of keen sympathies and philanthropic aims, but their emotions ripen into fruit too quickly, and are seldom found in a mature condition. They have a notion that their hives and system of management are far in advance of all others, and that straw hives and the destruction of bees by stifling are inseparably connected, and this notion they want to see carried, like thistledown before the wind, over the nation.

My opinion and experience oppose this notion, and I have no hesitation in telling this lady and all whom it may concern that she and they may have apiaries of straw hives second to none for beauty, convenience, and success, and that honey of the highest quality may be obtained from them without the destruction of bees. Nay, I hold that bees are more easily taken from straw hives than from other kinds. If our correspondent will follow my advice and practice she will get the honey from the old hives and put the bees in new and modern habitations. Hives containing about 2000 cubic inches of space should be provided with suitable boards, and when it is deemed desirable to take the honey the bees should be driven from the old hives and placed in the new ones.

In driving bees the smoke of fustian or corduroy is first blown into the hive (beginning with one at a time), then turn the hive upside down and place one about the same size over it, and roll a tablecloth round the junction to keep the bees inside. As soon as this is done the drumming on the sides of the bottom hives commences, and this drumming so confounds the bees that they run upwards, as for their lives, into the empty hive. In about fifteen or twenty minutes the bees are in the top hive, and should be placed on the spot where the old one stood. If it be the wish of the owner to introduce wooden or square hives the bees driven should be shaken into them as soon as they are driven.

All this is easily done, though to the beginner it seems a formidable task and undertaking. Everything connected with bee-management appears wonderful and difficult to uninformed beginners, and this lady correspondent will soon become an adept in the art of manipulating hives and bees if she begin and act as I have suggested. If the season for honey be over when the bees are put into empty hives they should be liberally fed, and of course if two driven swarms be united in one hive she will get three stocks only out of six swarms, but they will be better and stronger in pairs than if fed into stocks separately. As the hives are ancient we presume they are small, and therefore that it is advisable to unite them after they are driven. If the six swarms be all the stocks required the bees of the old ones could be united to them at harvest time. If honey be wanted from one or more of the swarm hives the bees should be driven as suggested for the old hives. The combs in the swarm hives are young and sweet, and the honey in them would be more easily taken than that in the old black combs. The aim of bee-keepers should be to have an apiary of large hives well stored with bees and food in autumn if great results are to be looked for in the year following.—A. PETTIGREW.

OUR LETTER BOX.

WHITE CHICKENS FROM BLACK HENS (C).—It is by no means uncommon to find white sports in black-feathered fowls. Spanish seem to delight in it. All black cocks are prone to throw red or yellow feathers, as Polands, Black Cochins, Crève-Cœurs. Spanish hens constantly moult white feathers, sometimes being splashed all over, sometimes becoming quite white. We therefore cannot see why their cousins the Minorcas may not do the same. It does not, however, render them more valuable. Quite the reverse—they are valueless. Persevering amateurs in times gone by produced white Spanish cocks and hens, but they found no admirers. The striking contrast between the black plumage and the white face was lost when the plumage itself became white.

REMOVING BEES (W. W.).—There will be great risk in removing your bees 300 yards from their present position across several gardens, for many of the bees would go back. As you are bound to remove your hives from their present stand, we advise you to remove them to some cottage garden or plantation three miles distant for a month; then bring them back to your new garden. About the beginning of August you should drive your bees into better hives and do as you propose—viz., "feed them into stocks." If you cannot conveniently remove the hives to a distance of three miles for the time being, drive them into the new hives at once and place them in the new position before they begin to work, for when bees leave a new hive for the first time they look well about them. If you act thus all the hives should be driven on an evening and the bees placed in the new garden an hour or two afterwards. On removing the bees obliterate the old stands completely, and let nothing of the old hives or coverings be seen near.

BEE HIVES (A Constant Reader).—Write to Messrs. Neighbour, Holborn, London.

DRIVING BEES (Fairfield).—In advice given to other correspondents you will find the process of driving explained, and shortly we shall explain the process of taking honey and wax.

UNSWARMED HIVE (Inquirer).—Your hive should be driven now, either by taking a swarm from it or by turning all the bees into an empty hive. First take the super off and put a lid on the crown hole, then turn the

wart on its crown (at a little distance from the stand) and place an empty hive on and over it, rolling a cloth round the junction. If you decide to take a swarm only drum for four minutes, then unroll the cloth and place the swarm on the board of the old hive and the old one on another board, which should be placed a few feet to the right or left of the old place. Twenty-one days after this has been done the bees in the old hive will have hatched all the brood in it, besides rearing a queen for themselves, and may be driven into an empty hive. You will thus get both a super of honey-comb, probably not quite full, and the old of honey, with two swarms which you must feed into stocks. If you do not want two stocks, the second swarm, which we call a turn-out, could be united to the first one. The other way is to drive all the bees from the stock into an empty hive at once, sacrifice the brood, and take the honey at the same time. If you do so you must drum on the bottom hive for twenty minutes or thereabouts. The first plan is the most eligible, and which is often carried out in our own practice. In all such operations we use plenty of smoke from fustian rags and seldom get stung.

WARTS ON COWS' TEATS (A Lady).—If the warts are only dry and hard they may be got rid of by a ligature round their bases of strong silk thread; should they be bleeding warts and accompanied by slight ulceration or soreness, a strong lotion made of alum in powder with vinegar added should be applied immediately after every milking. We have known cases where the animals have been so subject to warts that they will continue to come in spite of any remedy; it is then better to sell the cow at once, or dry her off her milk and feed her for beef.

REMARKS.

- 17th.—Fine sunny hot day.
18th.—Bright sunny morning, heavy clouds in afternoon, very warm day; beautiful evening.
19th.—Hot morning, little cloudy at times; very fine evening.
20th.—Very fine hot day, rather more wind; beautiful starlight night.
21st.—Beautiful day, bright and hot, rather windy and dusty; calm fine evening.
22nd.—Fine bright morning, overcast from 1 P.M., and very slight shower 1.30, not measurable; beautiful evening.
23rd.—Very dull and cloudy morning, sunny and bright with thunder in afternoon, which was louder in evening. Lightning five miles distant at 8.18 P.M.

A very warm week. The average daily maximum temperature in shade has been 83°, or 10.3° higher than in the previous week, but like it without measurable rainfall.—G. J. SYMONS.

COVENT GARDEN MARKET.—JULY 24.

THE great bulk of soft fruit has now passed through our market, Cherries and Strawberries being nearly over, as also Black Currants and Raspberries. With a fair crop generally prices have ruled good and must have well remunerated the growers. All hothouse fruit is lower.

From observations taken near London during forty-three years, the average day temperature of the week is 74.1°; and its night temperature 51.2°.

THE VENTILATION OF GLASS HOUSES.

Is the ventilation of our glass houses capable of modification? This is a question that has exercised my mind for some time, and the conclusion at which I have arrived is decidedly that it is. The matter is one of considerable importance, for the cost of ventilators and apparatus for opening and shutting them forms a serious item in the total cost of such buildings.

Nothing tends more to prove the general prevalence of a vague indistinct apprehension of the philosophy of ventilation than the various ways in which openings are made in the sides and roofs of buildings for the admission of air. One builder has a system of ridge ventilation consisting of a fixed elevated glazed ridge with flaps to open and shut; another has a ridge which can be raised and lowered at will; another has flaps along the roof; then there are flaps opening across the roof; sliding sashes, shutters in backs, walls, and openings in the ends of roofs, with various other contrivances which I need not enumerate; nor need I dwell upon the form of side ventilators, which range from wooden shutters up to costly contrivances for heating the air as it enters the house.

That plants growing under glass require fresh air all will admit, but very diverse opinions exist as to the manner in which it should be given them, and it is this of which I complain. A matter of such importance ought not to rest upon mere opinion, but should be reduced to simplicity by the test of cause and effect; for it is undoubtedly subject to the influence of natural laws, and we have only to find out what these are in order to arrive at a clear understanding of what is necessary to be done and how to do it. Let us do so. Open the ventilators along the top of a glass house, and the interior air, buoyant from warmth, rushes forth and is replaced by the fresh air from without, which may instantly be felt as it flows in, spreads to every part of the bottom of the building, becomes warm, rises, and escapes. We thus have perfect circulation, for the simple reason that heated air becomes so buoyant that it rises and the vacuum is instantly filled with the cold air which it displaces, proving the truth of the axiom that "heat is motion," and affording a capital illustration of the cause of wind for youthful students of natural philosophy.

This buoyancy of heated air enables us also to impart motion to the atmosphere of glass houses without opening a single ventilator, for by making warm the heating apparatus we cause the adjacent air to ascend to the glass roof, where it becomes chilled and falls downwards again, setting the whole volume of air in motion, so that during the prevalence of a cold cutting north-easter our tender exotics may be made to enjoy the benefit of warm air currents without the slightest exposure to the baneful effects of biting frost-laden draughts. To set this fact as clearly as possible before the readers I will tell how it first of all arrested my attention. I sat writing on an autumnal evening at a table close by a window wide and high, so high that it ran from near the floor to the ceiling

of the room, which was unusually lofty. The evening grew so cold as darkness crept on that a fire was lit in a grate immediately opposite the window; the door of the room was shut, and in a few minutes I became sensible of a cold current of air rushing downward upon my head, and which was so violent as to soon set me sneezing. I removed to the centre of the room and thus avoided the direct draught, which a little thought showed me arse from the air near the fire being warmed and made buoyant. It ascended to and along the ceiling, became cooled by contact with the upper part of the window, and instantly rushed downwards like an actual draught.

We thus find that by the agency of heat we impart motion to the air, and that by opening sashes at the highest part of a glass house we get rid of all vitiated air and afford the plants the benefit of a perfect circulation of fresh air. Such being the case, of what practical value are side or front ventilators? Surely in applying them to every form of glass house as has hitherto been done we have been wrong; and I submit that it is time this repetition of a costly blunder should cease. Let us only take care to make a large opening from end to end of the top of a range, whether it be for the culture of fruit or flowers, and the remainder of the building may remain intact. I say a large opening advisedly, because I have had repeated proof of the evils arising from the narrow openings now so prevalent.

It is unlikely that such a step out of the beaten track made hard by time and custom will pass unchallenged; I may therefore add that this is no mere theoretical idea, but is a sound and sure deduction from practical experience which I commend to the attention of every gardener whose undoubted duty and interest it is to reduce the cost of such buildings by every means in his power. Horticultural builders also will not be slow to introduce an improvement that is so much calculated to cheapen, and therefore to extend, the building of glass houses.—EDWD. LUCKHURST.

NORTH WALLS.

QUESTIONS are often asked of the Editors concerning what will do on north walls, and in our country rambles we so often see them unsightly and little used that I think it may be good to consider separately what may be done with them. First we will take the strictly useful part of the question, and look over the catalogue of fruits; then the more ornamental may follow; but it is impossible to keep the two entirely separate, for nothing can be more ornamental than fruit trees well stocked with bloom or fruit, and nothing can be more useful in such an establishment as I have to cater for than a wall covered with flowers fit for house decoration. More fruits will flourish in a northern aspect than is generally imagined, and in the southern parts of the kingdom some of them are better grown in such a position than they would be on a south wall.

The Morello Cherry, of course, stands first on the list, but May Duke and most of the early Cherries will do exceedingly well. Of Morellos, however, there never seem to be too many, and they always fetch a good price. A

fair-sized tree against a cottage will often pay a year's rent, and in addition to the paying part of the question it affords the prettiest clothing a cottage can possibly have. They need little attention in the way of pruning and training—indeed, they generally get too much, summer pruning and training being quite a superfluity unless the trees are growing very vigorously. From the middle of October to the middle of December is the best time to give them their pruning, and this consists in merely cutting out the weakest wood and that which has borne heavily. If insects have been troublesome, and there is any danger of their lurking in the shreds and crevices, it is best to unvail the trees entirely, so that the wall can be syringed or painted as well as the trees with something to make sure work of the enemy, bunching the branches up and slinging them to the wall or to stakes driven firmly into the ground. Nailing may be done at any time before the flowers expand provided the branches are not tied up too closely, but pruning should always be completed before Christmas. The most difficult as well as one of the most important things in Morello culture is the disbudding, and this, perhaps, had better stand over till the time comes round for it; for the present it must suffice to say that all misplaced shoots and those which are not likely to be wanted for succession are to be picked carefully off as soon as they are large enough to get hold of, while those which are left are allowed to grow in their natural manner till the following pruning time, when there is no difficulty in fitting them to their proper places. This mode of culture may not suit those who think more of trees trained in some fanciful form than they do of a crop of fruit, but as regards fruit-producing it is quite successful. Black aphids used to be a terrible plague to us before the days of duty-free ground tobacco, but a taste of this on any affected shoot soon makes clean work.

Some of the Plums I have proved to do exceedingly well on a north wall, and there are doubtless many others which would do equally well. Those I recommend from experience are Victoria, White Magnum Bonum, Golden Drop, Orleans, and Blue Perdrigon. I also recommend for trial in the same position Jefferson's, Cooper's Large, Impératrice, Mirabelle, and some of Mr. Rivers's early kinds. Marie Louise Pear is said by some people to do well in a northern aspect, and is worth trial. Of Currants, White Dutch and Red Grape are, I think, the best; and of Gooseberries Warrington and Red Champagne.

And here I must utter a word of caution to those who contemplate following the Longleaf plan of fitting up permanent netting for the preservation of Gooseberries and other fruits, and ask them to take a lesson from my partial failure. It is quite as necessary here to protect the buds in winter as it is the fruit in autumn, and I took fully into account that we should have extra labour in looking after the ordinary Gooseberry caterpillar when the birds were excluded. This was carefully attended to, and an almost clean sweep was made of the variegated host; but another enemy clothed in emerald has stolen in unawares, and a large portion of the trees became leafless in two days. The fly which produced this is not so large as that which produces the ordinary Gooseberry caterpillar. Of course I was not aware of the existence of this pest or I should have taken means for its eradication during winter. In future, however, if I build a Gooseberry house the roof will be moveable, to be taken off after the buds have started growing and replaced when the fruit is approaching the ripening stage, thus protecting from bud and fruit-eaters, and allowing our friends the insect-feeders to help us as they are always anxious to do. I enclose specimens of my new enemy in three stages, as well as two ordinary Gooseberry caterpillars.—W. TAYLOR.

[The larger specimens sent with the enclosed are only larvæ of the Gooseberry Sawfly (*Nematus Grossulariæ*), perhaps rather paler than the usual type. The small cocoons accompanying appear to be those of an ichneumonidean parasite that has been attacking the Sawfly larvæ. The latter not unfrequently defoliate the bushes in June or July, and the eggs ought to be looked after at an earlier period of the season. Shaking the bushes or hand-picking is the only remedy now. —J. R. S. C.]

DISBUDDING ROSES.

I HAVE already said something, but I wish to put in a distinct plea against the present practice of disbudding Roses.

Since the Rose show month my Roses have been doing exactly as they liked. They have been distinctly let alone, and the

result is to confirm me in my previous opinion—how much many lose by being shown without their buds; no doubt we obtain them larger, but in how very many instances the character of the class is entirely destroyed! I have before me a most lovely Marquise de Castellane with four buds; it might be a little small for "the box," but it is much nearer to perfection after its kind, and I incline to think that the foliage surrounding comes also broader and more profuse where the habit is not interfered with. This most remarkable season, in my case a perfect second season of blossom at the end of July, gives an opportunity of observing which the industrious exhibitor seldom obtains.

I am almost prepared to advocate forbidding all disbudding. Let as many little side blooms go as you please, but I would not have the three or four left on the exhibition bush at all interfered with. The sorts which have no buds can be as big as they please. With such a character as Paul Neyron, a large small family will really be found acting as a sort of wholesome check upon him. If this be thought impracticable could not our rulers of the National establish one class for Roses that have never been tampered with? Such are my sentiments. As an Irish poet remarked in his own day:—

"Lesbia wears a robe of gold,
But all so tight the nymph has laced it,
Not a charm of beauty's mould
Presumes to stay where Nature placed it!
Oh! my Norah's robe for me,
That floats as wild as mountain breezes,
Leaving every feature free
To rise or fall as Nature pleases!"

—A. C.

NOTES ON POTATOES.

OWING to the singular absence of frosts in late spring early Potatoes, which are so often injured in their early stages of growth, grew on comparatively unchecked. The rains of May and early June succeeding rendered the growth generally strong, and the heat and drought of July has accelerated the ripening of the tubers. I have never had, nor remember having seen, more satisfactory crops of early varieties than are now being dug for daily use. Although the haulm is still comparatively green the tubers, in consequence of the drought, are of superior quality, and they are as yet untainted with disease.

It is of the greatest importance that the crops now sound and good should be kept so, and so far as I know—and I have made many experiments—there is only one way of doing it, and that is by digging them up and storing them carefully.

Of late years the rule in regard to weather changes has been the setting-in of distinctly marked periods of intense heat and drought extending over several weeks, and then, as if Nature was affording compensation, a term has followed of incessant and protracted rains. Already we have had an example of these extreme changes. We had the rainy period of May, followed by the drought period of July. Rain is again due. It may come quickly, even before these notes are printed, and it may be both heavy and long-continued. In that case the early Potatoes if left in the ground will be much injured—it may be ruined. Even if they are not overtaken with the murrain they will commence growing again (supertuberating), and the produce will lose much of its present high value. Within a week from the date of writing (July 25th) I shall not, weather permitting, have a single root of early Potatoes left in the ground. Wherever I find the tubers have about attained their full size they will be taken up, even if their skins are not firmly set, and if the foliage is yet unwithered. All the varieties of Ashleaf are ready for lifting, as also are some of the earlier of the American sorts. The tubers will be spread as thinly as circumstances permit in a dark place—as dark as pitch for those intended for cooking purposes, but those for planting will not be injured by having some light, but exposing them at once to the sun I have found more injurious than beneficial. By a little forethought and scheming shelter can mostly be improvised for the tubers, which in the case of the earliest sorts seldom amount to many sacks, and they are at least as worthy of extra effort and special care as is often exercised in wintering scarlet Geraniums. The safety of digging-up Potatoes before they are thoroughly matured has been strongly advocated in your pages by Messrs. Luckhurst, Wright, "A NORTHERN GARDENER," and others, and many years of experience warrant me in confirming what has been published as to the excellency and usefulness of the practice then and now recommended.

Although the disease has not yet manifested itself to any

great extent, yet the second early and midseason varieties are in extreme jeopardy. The tubers are about half grown, and in that state are extremely susceptible of injury when protracted rains occur after a long term of hot dry weather. Nothing that I am aware of can be done to save them; they must take their chance, but the moment the tubers are large enough for use up they should come. Late sorts are much more safe. They have not, at least in the midland and northern counties (I cannot answer for the south), yet formed their tubers on account of the intense heat and drought, and as soon as a rainy period sets in the crops will grow on without supertuberating, and without, at least for some weeks to come, being overtaken by disease.—AN OLD GROWER.

THE SETTING-UP OF GRAPES FOR EXHIBITION.

RULES made which afterwards are allowed by those who framed them to be broken with impunity place their sponsors in much the same somewhat unpleasant position the grower of fruit is placed in when not allowed to exhibit his fruit to the best advantage his taste, or it may be his ingenuity, devises.

A visit to the Royal Horticultural Show lately held at Preston and what I saw of the way Grapes were exhibited there, a later visit to the Newcastle-upon-Tyne Show and requisitions that I saw made there, and the perusal of the rules of the Durham Show which is still to be held, are my reasons for the present article.

Uniformity without stiffness I have no objection to, and I am so far in favour of evenly displayed fruit that I would appreciate the motives of any committee that gave the description of any particular stand, or the height of any stand at front or back, to secure uniformity; but such foolish requirements as demanding Grapes to be laid on nearly flat stands, and in some instances even demanding that they be exhibited on plates, are requisitions that I demur to—in fact, I feel pretty much inclined to join a rebellion against them. At Preston a special footnote in the schedule stipulated that Grapes must be exhibited on stands 8 inches high at the back. A friend, Mr. McConochie, after setting up his exhibits, happening to lend me his schedule I at once detected the instructions given and reminded him that his stands were 4 inches too high. After thanking me for drawing his attention, he not having previously noticed the rule, his next thoughts were how to alter his stands with the Grapes upon them to comply. Being somewhat of an adept at the joiner's craft, this to your correspondent was a difficulty easily overcome, but most certainly at the expense of having his Grapes less advantageously exhibited—his Black Hamburgs, being very ripe, afterwards fell flat. Some others had complied with the rule and some had not complied, and perhaps there were some "out of it" who did not care to comply. At the last moment Mr. Coleman, the lion of the day, set up with stands quite 12 inches high and was awarded first prize. There was some talk of an objection, and which was not an unreasonable one, but as I had to leave I know nothing further of the matter, and have nothing more to say, save that the requisition did not admit of Grapes being set up to the best advantage, and that I am glad Mr. Coleman evidenced a commendable spirit by disdaining to have his extremely well-grown fruit that had cost him so much care insulted by, I might reasonably describe, being laid flat on the table.

At the Newcastle Show the rules, I believe, make no stipulation, but notwithstanding some members of the Committee ordered the fruit to be taken off the stands and to be laid flat upon plates. A nice predicament this a gardener to find himself in, and especially one who, perhaps, only finds himself justified in taking a sufficient number of bunches from his stock that are necessary to set up at one show, and yet who has arranged to exhibit at some three or four. Such requirements submit the exhibitor to an unnecessary injustice, unnecessarily militate against his successfully competing where he has every right to compete, and with the same produce.

Just a passing word regarding the Durham schedule. This Show does not receive the patronage it deserves; the Durham people do not subscribe so liberally as they ought to do. But it is the rules I am criticising. Fruit I find must be exhibited on plates, and at Durham you must find your own plates. The next thing, I suppose, shall be—exhibitors will have to be followed to the exhibition with a retinue of potters, or perhaps a camp of gypsies, as, before making their purchases exhibitors will have to learn of the committee whether their taste goes in for brown or for white ware. If you want uni-

formity, if you want taste, if you want exhibitors to set up their fruit and other produce in a way which will delight the public to come and see it, add this clause to your schedule and you will succeed:—Of all exhibits, where other merits are considered equal, the judges are desired to give the casting vote in favour of the most tastefully arranged; then at our exhibitions we shall have examples of better taste, and consequently more attractive displays.—J. WITHERSPOON.

HEREFORD ROSE SHOW.

IN answer to "A LOVER OF ROSE SHOWS," and now that the pressure on your space is not so great, perhaps the following remarks may not be unacceptable.

The Judges who adjudicated on the amateur classes were the brothers Gater, and two more excellent Judges it would be impossible to find in England. One is (for the information of those not acquainted with them) the Rose foreman to Mr. George Paul, the other holds the same position in the establishment of Mr. Charles Turner. We had therefore two men whose whole time is devoted to the cultivation of Roses, and who from long experience and the constant supervision of Roses know perhaps as much about them as any other two men to be found.

As to my remarks, quoted by "A LOVER OF ROSE SHOWS" in the paragraph immediately preceding the one in which he so kindly speaks of me, I must freely own that before the judging commenced I felt confident that Mr. Jowitt would win the prize. I formed this opinion from the points enumerated by your correspondent—viz., evenness, more Teas, and greater diversity of colour; and I can well imagine that other judges would have reversed the decision if appealed to; but the Judges on this occasion went to work evidently upon the rule of counting points. And here Mr. Baker won; for some of his blooms were magnificent—blooms not only above the average, but such as are rarely seen. When, then, the weak blooms in his stand were counted they only reduced the sum of his number of points by a mere fraction. Mr. Jowitt's blooms were all good, but perhaps he had more mediocre blooms than those which could be called superb. But certainly he had no tail, while Mr. Baker had a very decided one. The matter was simply resolved to an addition sum, and here Mr. Baker obtained the highest numbers and won.

During the day the judgment naturally attracted considerable attention, and several of the best judges went very carefully through both stands, but on the whole their conclusions coincided with that of the Judges. "I think it is right," was Mr. Cranston's remark; while a distinguished amateur, who is, I believe, the President of the Society, said, "Well, I hardly know, it was so very close. I am only glad I was not a judge." I mention all this for the sake of showing "A LOVER OF ROSE SHOWS" how close the contest was. If Madame Charles Wood had stayed at Heavitree and Capitaine Christy wooed her there instead of shedding tears over her at the Shire-Hall, then there would have been no question about the matter, for Mr. Baker would have been undoubtedly first; but the eye of the connoisseur would keep ranging up to that unfortunate couple in the back row of the second box, and then turning to his great rival's box, which was placed next to it, looked in vain for so bad a flower. Such are my impressions, and as both competitors are dear and valued friends of my own I can state them, I hope, without fear of offending either.

Your correspondent will observe if he turns to the rules printed in last week's Journal that points are recommended in case of a close contest—three points to the best blooms, two for mediums, and one for those not bad enough to be cut out, and an extra point for a very superior bloom. On this principle I believe the Judges acted at Hereford, and there can be no fairer and better way of judging.

Now, in conclusion, may I say a word about the forthcoming Rose election? I have refrained hitherto from saying anything about the last for fear of giving offence, and also thinking that it would be the last of those which had reference to exhibition blooms; but now that there is to be another election I must have my say.

To make this election any guide of value or use to the leading exhibitors more care must be taken in the selection of the electors.

I wish to mention no names, but I am sure electors sent in lists last year who had no qualification. As an instance of this I may mention the following as a proof that no care was taken to find out the qualifications of an elector. I happened

to write you an article upon disbudding and mentioned the case of a very successful grower of garden Roses who did not disbud at all. My neighbour never exhibited a Rose in his life, except at the small show held in his own grounds; yet directly his name appeared in the Journal Mr. Hinton sent him a form of election. This was sent on to me with a request that I would explain what it meant. Now if this style of things is to be followed again, what guide will the list be? Let the returning officer not accept a list without knowing the elector's qualification.

If he asks me how he is to do this, I answer, In the easiest possible manner. Let him write a letter to the Rev. Honywood D'Ombrian and ask him to furnish him with a list of the successful exhibitors at the two National exhibitions this year and last; and also write to the Rev. C. Bulmer, Credenhill Rectory, Hereford, for one of those at Hereford; and to the Secretary of the Alexandra Palace also. Then from these and other lists obtained on the same principle collect the names, send polling papers only to those, and a list of some value will be formed: if he does not, the result will be, what I do not hesitate to declare last year's was, "a delusion, mockery, and a snare." With this conclusion I need hardly sign my name, but it is—WYLD SAVAGE.

SEASONABLE NOTES ON KITCHEN GARDEN SOWING.

THESE notes appearing in the Journal on the 1st of August will just be in time to remind many of your readers of some particular kitchen garden seed-sowing which should be done about that time. In northern parts Cabbage seed, for producing plants that will come early into use next spring, will have been sown a week or two ago; but it may be well to remind them, especially those who have neglected to sow, that it is not yet too late to do so, but it very soon will be if early plants and early produce are desired. Even those who have sown some weeks ago will do well to make another sowing now, because if the autumn should be mild and the winter open many of the first sowing may bolt in spring before hearting, and it is always wise to have a reserve in hand. At the present time the seed should be sown in rich ground and an open situation. When the largest of the plants are fit for transplanting they may be drawn, and of those left standing in little crowds the best way is to take them up also and dibble them into a fresh piece of ground 3 or 4 inches apart.

After Cabbage I think winter Turnips come next in importance. Sweet, fresh, small roots of these are very acceptable throughout the winter, but I do not think that many amateurs or cottagers understand this, or they would grow them more frequently than they do. Any kind of ground that has been used for early crops and is now cleared will do for Turnips. If it is hard on the surface, break it with the fork; if loose, only level it with the spade or rake, and sow the seed in drills 18 inches apart. A good patch sown now will supply bulbs from November until April. The plants must not be left too close together, as they do not bulb well when crowded.

Onions of the Tripoli section should also be sown early in August. They may be sown from the first day until the middle of the month either in drills a foot apart or broadcast, and in a sheltered but not shaded position. The seed should be sown very thin, as if the plants come up 1 or 2 inches apart they are quite close enough to stand the winter.

Winter Spinach is another useful vegetable that should be sown now and during the month. We grow it in rows 1½ foot apart, and it is generally sown on ground that has been newly cleared of Potatoes. This vegetable is often considered a delicacy with many, but it is indispensable where many varieties of vegetables are wanted in winter.

Where salading is appreciated in winter a good breadth of Lettuce and Endive should now be sown. Of course no one will keep ground empty throughout the summer waiting for this or other crops that are sown at this time, but let them follow Cauliflower, Peas, Potatoes, &c. We draw drills 1 foot apart and drop a few seeds in every foot, and when the young plants come up they are all drawn out but one in each cluster, which is left to form the crop. When they are thinned in damp weather those drawn out may be transplanted into other ground.

A small sowing of Cauliflower may now be made, and another in a fortnight or so to furnish plants for supplying the earliest heads next year.

It is not too late to sow seed for winter Cucumber plants. They should be started in a gentle heat and grown sharply on so as to make strong plants by the month of October. We have grown many sorts of Cucumbers this summer, including Tender-and-True, but with us neither this nor any other kind equals Telegraph, which is undoubtedly the best all-the-year-round variety extant. I might add a few more notes on the kitchen garden, but all this kind of information is now given so thoroughly up to the times in your Work for the Week that it is hardly necessary for me to say what I have said, only the subjects referred to are so very important at the present time that there can be no harm in drawing special attention to them.—A KITCHEN GARDENER.

AN EVENING AT LAMBTON.

"VALERIANA PHU." Those are the only two words in my note book having reference to the famed gardens at Lambton Castle, what I write therefore will be from memory. My remarks will consequently be general, which is all that is necessary, as a full and detailed account of the gardens has appeared in the Journal from the pen of the veteran correspondent Mr. Robson; but to the Valerian, for it may be well to dispose of it first. As many readers are aware this is a very old hardy perennial, so old that it was introduced from Germany nearly three centuries ago, and is generally considered of little value, and receives, as a rule, little cultural care. At Lambton, however, this plant, or rather what I presume is a golden sport from it, is grown by thousands for the decoration of the flower garden in spring. Its foliage now is pale green, but in the spring Mr. Hunter states that it assumes a brilliant transparent yellow hue quite surpassing the Golden Feather, and this Golden Valerian is esteemed one of the most useful and effective of all spring-bedding plants. So much for Valeriana Phu.

Lambton Castle, its pleasure grounds and gardens, are situated on the northern declivity which rises somewhat abruptly from the river Wear, a tidal river which has its effluent at Sunderland. The banks of the river are in some places precipitous, and are densely clothed with fine timber trees and a luxuriant undergrowth of wild vegetation. The view from the Castle down the immense ravine at its foot and onward to the opposite bank, with its undulated far-stretching mountain of foliage, is one of dignity and grandeur. From the pleasure grounds, too, the vistas, tastefully opened out here and there from various points of vantage on the curving walks, bring into view scenes of great natural beauty. Views similarly commanding and highly picturesque are also obtained from the terraces, whereon are erected the extensive ranges of glass structures, and from the attractive, commodious, and convenient residence recently built by the Earl of Durham for his trusted and competent gardener Mr. Hunter. The Castle may be said to be near one extremity of the pleasure grounds and gardens, and Mr. Hunter's residence near the other. Between those two points immense labour has been expended in excavating and levelling for the various walks and buildings, and great successes have been achieved both as regards general effect and conveniences, and not less so in the cultivation of fruits and the raising of new varieties. Rising high above the grounds and gardens is a dense sheltering background of trees, and below, as before observed, is the chasm-like valley of the Wear and its gently winding river. Such is the general character of Lambton. Let us now look a little more closely at a spot which Nature and Art combined have made so attractive.

As a matter of convenience we may commence at the lowest and easterly point and travel westward and upwards. Descending the slope from Mr. Hunter's residence we "land" in a comparatively new unvalled kitchen garden of about four acres. After much labour this piece of ground has been rendered fertile and valuable, whereas a few years ago it was a wild morass. It was only slightly above the tidal level of the Wear, and some idea may be afforded of the labour involved in its reclamation when it is stated that a depth of 9 feet of soil was carted to bring it to its present comparatively safe cultivable state—comparative because during periods of floods the overflowing river occasionally submerges it. The lowest part of the ground is the broad central walk, from which the ground rises on either side, forming two long and rather steep banks. Thus the crops can be seen to great advantage, and well they look. The heat and drought has been extreme at Lambton, but the best of all means has been

adopted for counteracting their effects—namely, all the principal crops were timely and heavily mulched. In cropping the sensible plan is adopted of growing extensively a very few varieties of vegetables—those that have proved themselves best adapted to the situation, and which are of approved quality. Pyramid fruit trees fringe the walks—handsome well-trained specimens, just arriving at a bearing state. A few have good crops, but the blossom in such a low position often suffers by late spring frosts. This garden is bounded on the west by the walled kitchen garden, and here on one of the borders, which is very wide, a capital plan was adopted of preserving fruit from birds.

The wall is covered with fruit trees, and the border is also planted with bush fruit trees bearing heavy crops. Along the front of the border next the walk a few neat posts and battens are fixed, and from this framework other battens reach to the top of the wall; the whole is then covered with netting, made secure at the top ends and bottom. By opening the netting at one end the fruit can be gathered both from the wall and bushes with the greatest convenience, the height of the netting affording ample head room for the gatherers. The same mode of growing and protecting fruit is practised at Potholm near Langholm, N.B., Mr. Taylor's small but good garden, lately managed so successfully by Mr. Bole, now of Somerleyton. The bushes grown on the borders do no more harm to the wall trees than the trees sustain by the usual and generally heavy vegetable cropping that is practised, and a valuable supply of fruit is prolonged to a late period of the year. The south wall of this the old kitchen garden is both lofty and substantial, as it is the supporting medium of a large terraced flower garden, which is laid out in front of one of the chief ranges of glass, access to which is had from the lower garden by flights of stone steps. From the balustrade at the top of the steps a commanding view is had of the flowers on the terrace, the flowers below which are tastefully planted in ribbon and carpet fashion on the wide borders of the central walk crossing the garden (with the large fountain in the centre), and of the flowers beyond the walls disposed on grass in the pleasure grounds. The kitchen garden under notice is cropped similarly to the other with vegetables and fruit trees, and the side borders where not occupied with summer flowers are employed as nursery strips for spring-bedding plants, of which seventy thousand are required annually—the *Valeriana Phu* above noticed, *Aubrietias*, *Daisies*, *Pansies*, and *Wallflowers* appearing to form the staple sorts. Everything in the kitchen garden department looks well, except weeds; of these there are none. When the culinary department of a garden is kept in the high order that prevails at Lambton it is as enjoyable as any other portion of an establishment under the gardener's care.

Still pursuing a westward course on the lower ground we pass from the kitchen garden to an open lawn, across which a broad curving walk traverses flanked with wide flower borders. These borders are arranged in a series of beds of the Florentine chain pattern edged with Box, the narrow paths between the scrolls being surfaced with white and red gravel. It is not necessary to particularise the mode of planting, but it may be remarked that although no rain had fallen since the beds were planted the yellow *Calceolarias* were flowering splendidly, the earth moisture being sufficient thus far to sustain the plants; but unless a change speedily occurs and showery weather succeeds their beauty will soon be over. Another plant is worthy of mention—Harrison's Giant Musk. Although exposed to the full influence of the sun the plants are growing luxuriantly and flowering profusely, and Mr. Hunter has great hopes that this Musk will make a valuable bedding plant at Lambton. The beds referred to are very large, the design probably exceeding 12 feet across, and its considerable length and graceful curves render this portion of the garden remarkably cheerful. On the lawns on both sides of the walks are a few Conifers, and on three sides out of four is a dense background of trees. But although ornament is the essential feature here it is made to contribute to utility: on one side of the walk is a miniature pond for aquatics with a rocky margin for various hardy plants of semi-aquatic nature. The overflow from this circular pool is conveyed under the walk, and is turned to account behind the shrubs for the growing of Watercresses. In an open and ever-running stream of clear water an abundant supply of "sweet Cresses" is always ready for cutting. Near this point a suspension bridge crosses the Wear, and is both useful and ornamental.

We pass onwards through the shrubbery, which is a dense thicket of vegetation. Rhododendrons are the predominating

evergreens. The ground is boldly undulated. On one hand are mounds steep and high, on the other such dells as Nature alone could form. Ferns luxuriate and wild flowers grow in refreshing masses between and amongst the trees. In the spring the ground is covered with a dense carpet of blue—the wild blue *Scillas*, which grow in countless millions all over the place. Here and there are openings of lawn studded with choice Conifers, which grow fairly well in this country of coal. These shrubs like a pure clear air, but in Durham they have to struggle with an atmosphere more or less contaminated with smoke. Coal mines are all around us and beneath us—the Earl of Durham owning sixteen pits—yet so well is the estate wooded that not one chimney is visible and smoke is seldom seen, but the Conifers feel it. We reach the Castle—a huge strong pile with its plain gravelled terrace on the south side, and expansive flowerless lawns on the west and north. A few, very few, flowers are planted near the walls on one side, and a few others are arranged in handsome stone vases made on the premises, but the lawns contain, and properly so, no flower beds. There is something incongruous when modern carpet bedding is associated with severe Norman architecture, with which only fine trees irregularly planted fittingly harmonise. There is plenty of room for flowers on such grounds as these without unduly encroaching on the Castle, and flowers there are, for a hundred thousand plants are planted every year.

Allusion has been made to the great expenditure of labour that has been necessitated in forming the grounds and gardens, but the most stupendous task of all has been in rendering the Castle firm and secure. The ground for miles has been honeycombed for coal, and although the seams are some hundreds of feet below the surface, yet the immense weight of the massive stone pile was too great for the crust on which it was built. The sinking of the building was, of course, unendurable, and equally unendurable was the thought of its abandonment. A gigantic work was undertaken, even nothing less than building up from the firm seams deep down in the earth to the base of the Castle. In this work fourteen millions of bricks were used, and relays of men were uninterruptedly engaged night and day for seven years. It was an extraordinary undertaking, but it answered the purpose, and the Castle is safe.

Returning on higher ground we find ourselves on the terraced flower garden above mentioned as overlooking the kitchen garden. It is a long expanse of flowers about 18 feet wide arranged in a pleasing design. It reminds us of the fine borders at Archerfield, where Mr. Hunter formerly practised under a skilled tutor, Mr. David Thomson. We pass along the terrace to the east front of the long range of glass, enter, and again travel westward.

The Grapes of Lambton are of national fame. At the greatest exhibitions in the three kingdoms they have won high honours, and Mr. Hunter is by general consent placed high on the list of successful British cultivators. A glance at the Vines that have produced such remarkable fruit as history has recorded cannot fail being interesting. We are in a grand vinery 100 feet long, lofty, and with a good length of rafter. For years past the Vines in this house have produced splendid Grapes. The secret, if it is any secret, of Mr. Hunter's success is not far to seek. It is stamped with tolerable clearness on the Vines themselves. They are in a good larder, that is clear; for their strong rods, stout but not gross laterals, and fine but not exuberant foliage, speak plainly on that point. They have good soil, are well drained and copiously watered. So much for the roots; now to the disposition of the branches. As may be expected they are thinly trained. The rods are wide apart, and the laterals are so arranged that every leaf is permitted to expand on which the sun can shine, no more nor no less. That is a great point in Grape-growing. Overcrowding of the laterals and foliage is a great evil, perhaps the greatest and most common of all errors in Vine culture. Let the border be ever so good, there can be no fine Grapes unless the foliage is perfectly developed, and there can be no really good foliage unless every leaf has full exposure to light and air. But while overcrowding is so pernicious, another evil, it may be a lesser evil and less prevalent, but still an evil, is overpinching. "Pinch the shoots at one leaf beyond the bunch" was at one period in history rather stereotyped advice. It was, however, and is unsound advice if the Vines are thinly planted and the rule-of-thumb pinching is so rigidly adhered to as to leave long-lines of glass a foot wide visible from below. The unutilised light is so much loss to the Vines. At Lambton the laterals are in the first place thinned sufficiently that the leaves of one do not when expanded overlap those of the other. They are

then stopped, not at one, nor two, nor three leaves beyond the bunch—are not, indeed, pinched on the counting system at all, but every leaf is permitted that can expand without encroaching on space required by its neighbour. That is the only truly rational system that can be recommended for stopping the shoots. Another important lesson is conveyed by the Lambton Vines—they are not overcropped. The crops are good, bunches large and full, and berries fine and finishing well, but care is evidently taken that the crops are not of an exhaustive nature, or such excellent results could not have been achieved over such a long period. Several varieties are fruiting in this house. Gros Colman is free and fine—plenty of bunches, and huge berries colouring well. It not only looks well, but I am told it is invariably of good quality at Lambton, which is not the case everywhere. Alicante is splendid, Calabrian Raisin imposing, Golden Champion attractive by good and full bunches and clear berries, only a very few being slightly spotted; but one of the finest crops is on Gros Guillaume. Grafted on Muscat Trovère (Trovère Frontignan) the bunches are of fine shape and noble size, the berries also being very large and colouring well. A cane of Alnwick Castle Seedling was inarched on one of the Vines in the spring, and a small bunch that it produced was allowed to remain; it is colouring excellently, and Mr. Hunter considers it a Grape of much promise. Passing many other varieties on the roof, we glance at the back wall. Some years ago a Vine was planted in the cold north border behind the house; and its cane being brought through two walls into the house it grew freely, and two branches were trained horizontally (one each way from the centre where the Vine entered) near the base of the wall, from which rods were trained vertically at distances of 3 or 4 feet. The Vine not only covered the entire wall but has produced Grapes of the first quality, and it has further entered the next house and has there covered a great extent of space. It has, however, nearly done its work, and cannot be expected to continue much longer bearing well under the densely covered roof. Let no one jump at conclusions and request Vines being planted for producing fruit on the bare back walls of their vineries. It is no use planting Vines in such positions *after* a roof is covered with foliage, but if planted at the same time as Vines are planted for covering the roof valuable crops of Grapes may be had for a few years from the back walls of vineries. I shall shortly notice a successful example of this when referring to a wonderful instance of Vine culture by an amateur, Mr. Witherspoon.

Other vineries at Lambton demand notice: it must necessarily be brief. The Muscat house contains large, full, and capital bunches just in their finishing stage. A striking example of sap-diversion is to be seen in this house. A young cane brought from the front of the house was inarched to a Vine several feet up the roof. After the union was effected the inarched cane was severed about 4 feet below its junction with the other Vine; but although severed the part below the union continued growing, and has there produced a bunch of Grapes quite equal to any other on the Vine, proving that the sap has flowed in a reverse direction freely. A modicum of support is probably derived from a bottle which Mr. Hunter has attached to the severed portion of the cane; but undoubtedly the great bulk of nutriment is afforded by the Vine on which the cane is inarched. The Black Hamburgh house in this "low level" range also contains many fine bunches, and large, hammered, and well-finished berries. Passing as a matter of convenience other houses of plants, Peaches, &c., in this range, we ascend the upper terrace to glance at the Grapes there. The late house may be described in few words. It is very lofty, and a totally different system of culture is practised than prevails in the other structures, the object being the production of a great number of small bunches of such Grapes that are required to keep until Grapes come again—sound policy, as all know who have such work to do.

We now linger in a house of Black Hamburgs, which has upset some preconceived notions of turfy loamists, and which is a standing rebuke against dogmatic teaching on the subject of soil for Vines. It has almost become fashionable to advise that no manure be placed in Vine borders, but that manure be placed on the surface, and where soil is tolerably fertile such advice is, doubtless, both safe and sound; yet manure is not the dangerous element that is popularly supposed, or the Vines in this house would not be in the condition they now are. They were planted as an experiment five years ago in a mixture of tree leaves and cow dung mixed and trodden firmly to a depth of 3 feet. Not a barrowful of soil of any kind was used in the

border, which is inside the house. The front wall was cemented to keep the roots inside. These manure-grown Vines have produced splendid crops, and Grapes are hanging now worthy of being placed on any nobleman's table—good bunches, and large black berries of the first quality. The Vines, too, both as regards wood and foliage are in a most satisfactory state. For the sake of appearance the border is slightly covered with soil. Free permission is given by Mr. Hunter for any visitor to dig down as deep as he likes to examine the border, and a fork is kept in the house for that purpose. Many trials have been made, and all with the inevitable result that nothing but manure is dug up and masses of fine healthy roots, no roots being found in the surface soil. The border is not a pasty mass, but has simply changed as manure in heaps invariably changes, to a mouldy bulk of rich humus. The Vines evidently enjoy it as much 2 and 3 feet deep as they do when spread on the surface in the form of heavy top-dressings. The distance is an impediment, or Grapes from this house would probably be submitted to the Fruit Committee of the Royal Horticultural Society. As a result of the experiment it may be stated that in new Vine borders projected at Lambton manure will be mixed with the soil freely. It may be mentioned incidentally that manure is liberally employed by the market growers of Grapes near London for incorporating with the soil of their Vine borders, and heavy crops of excellent Grapes are produced.

Lambton, too, is famous for Pine Apple culture. The plants are grown in light and lofty—too lofty—span-roofed houses. They are chiefly grown in pots, but some are planted out. All are in admirable condition, and good fruits are plentiful; but it is to the seedling Pines that most interest attaches. In the raising of new varieties, as the result of artificial fertilisation, Mr. Hunter has had great success. Of one of the finest of the Lambton seedlings—Lady Beatrice, a good stock of plants is raised, and propagation is being conducted as quickly as possible with a view of their distribution to the public, Lord Durham having kindly and generously placed the stock of these seedlings at Mr. Hunter's disposal. The raising of a stock of new Pines is a work of patience, for though a seedling Pine may be fruited within two years any considerable number of the same variety cannot be produced under several years. All the plants, old and young, are remarkably healthy and very clean.

A new Fig, the Lambton Castle Seedling, in one of the houses arrests attention by its prodigious crop. Fruit is produced at every axil, a large tree being simply wreathed with fruit, and plants not more than 6 inches high in small pots are also bearing fruit in clusters. This Fig is not only by far the most prolific of all the Figs grown at Lambton, but it is esteemed by the Earl of Durham's family as the best of all in quality.

Large houses are devoted to Peaches and Nectarines. One large structure was particularly noticeable. Standard trees cover the back wall, and a large trellis is also covered with trees. Under the trellis, which is lofty, a row of Plums is planted near to the walk, which is at the back of the house, the trees receiving light from the glass over the pathway. All the trees in the house, Plums included, are bearing excellent crops. The Plum trees grow in their natural manner, and receive very little of either pinching or pruning. They cannot fail being useful, producing as they do many valuable dishes of fruit. Cape Gooseberries are also grown in the same house. Cucumbers and Melons are largely grown, and at the back of some of the highly heated structures Tea Roses are planted out in troughs, and grow and flower admirably. They are not trained, and appear to receive little pruning beyond that given by cutting the blooms.

Nothing as yet has been said on plant culture. Many plants are grown, and grown well—not large symmetrical specimens, but fresh healthy plants for decorative purposes. The conservatory is in the centre of the "lower level" range of glass, and reaches back to the higher terrace, necessitating a flight of steps in the interior. This structure was undergoing alterations, and the Tree Ferns, Cycads, Palms, &c., were disposed for convenience rather than for effect. In addition to the two long ranges of glass alluded to, some large preparing plant houses are erected still higher up the hillside. The centre bed of one large house was covered with a luxuriant growth of *Pittonia argyroneura*, which not only had a pleasing effect, but prevented the soil in the pots of the plants placed amongst it drying so speedily as if the pots were exposed. Many plants in small pots had their pots placed in larger, the space between

the pots being filled with cocoa-nut fibre refuse. Much labour in watering was saved, and the health of the plants was promoted by the adoption of that practice.

Between the two primary ranges of glass a long grassed terrace is formed and laid out as a flower garden. The beds are extremely gay, and whether viewed from above or below, or from either end, have a very cheerful appearance; but what strikes the visitor most, taking the upper terrace as a standpoint, is the elaborate manner in which the back walls of the vineries on the lower range are ornamented. Formerly unsightly, they are now, after the exercise of much skill and patience, a remarkable feature of the gardens. They are covered with *Pyracanthas* (*Crategus Pyracantha*), but in a very different manner than walls are usually covered with that useful evergreen. The *Pyracantha* for about 2 feet from the ground is cut, forming a hedge about 6 inches in thickness; above the hedge and for a height of about 4 feet branches are trained in the form of trelliswork; above the living trellis-work growths are trained so as to describe the names of two of Lord Durham's daughters, which are written most accurately and clearly in Roman capitals about 15 to 18 inches high; above the names runs a finishing cornice, which completes the covering of the wall. On one side of the conservatory which divides the border is the name, if I recollect rightly, of "The Lady Louisa Beatrix Lambton," and on the other "The Lady Eleanor Katherine Lambton." The slender branch supporting each letter is kept denuded of foliage, and at a short distance from the wall is not perceived, which renders the arrangement all the more novel. The accuracy with which the work has been carried out, and the trimness and clearness in which it is kept, constitute a living record of taste and patience. The walls supporting the houses are also covered with *Cotoneaster microphylla* trained in small squares, and the effect produced is unique. On some other walls Gooseberries are trained in the same manner.

Another striking feature at Lambton demands notice—namely, the splendid provision that the Earl of Durham has recently made for the comfort of those who are engaged in his gardens. Mr. Hunter's beautifully situated residence has been alluded to; it is replete with every convenience. The newly erected young men's rooms are models of their kind; every requisite is provided for promoting health, and provision is also made for sickness. Every man has a carpeted bedroom, and there is a bathroom with "hot and cold water always ready." And then there are the labourers' cottages also new, and such that are seldom met with. They are artistically built, yet are commodious and convenient, and the flower gardens in front are equal to many in gentlemen's gardens. No doubt the men value highly such dwellings, and they will not value them the less when I tell them that such houses in the vicinity of London would be considered cheap at £30 a year each.

In this review of a fine, well-managed, and excellently kept garden I have forgotten much that is worthy of mention; but one thing I cannot forget, and that is the genuine welcome I received and the few pleasant hours I spent with Mr. and Mrs. Hunter during my "evening at Lambton."—J. WRIGHT.

ESTIMATE OF THE VALUE OF THE APPLE CROP IN HEREFORDSHIRE.

THE following extract, which attempts to give a rough estimate of the annual value of the Apple crop in Herefordshire, is taken from the retiring address of the President, J. Griffith Morris, Esq., to the members of the Woolhope Naturalists Field Club:—

"The study of pomology is not strictly within the range of natural science, and yet in a county so celebrated as is Herefordshire for its Apples and the wine made from them, it is a study of paramount importance. The members of the Woolhope Club have often considered this subject, and in consequence of a conversation held at the Fungus Foray of 1873 the Rev. M. J. Berkeley sent down grafts of the most esteemed varieties of Apples from the gardens of the Royal Horticultural Society of London. These sorts, ninety-five in number, were distributed among the members of the Club and to the leading nurserymen in the county. In 1876 an exhibition of Apples was held under the auspices of the Club, and this was repeated very successfully last year.

"The value and quantity of Apples grown in Herefordshire, and of the cider made from them, is but very insufficiently appreciated. From official returns condensed in the 'Farmers' Almanac' of 1877, by Mr. Webb of Tunstall, it appears that about

4 per cent. of the total acreage of Herefordshire is laid down in orcharding. The total area of the county is 532,898 acres, and therefore 21,500 acres is the extent of orcharding. With this basis for calculation it seems possible to arrive at a rough estimate of the value of the Apple crop.

"In these days of cheap and rapid transit all Apples of size and colour meet with a ready sale for edible or culinary purposes. At least one-quarter of the fruit grown is now sold in this way and called pot fruit; the remaining three-fourths is made into cider. To consider first the cider fruit at the very low average of 60 bushels of fruit, or three hogsheads to an acre, it will produce 48,375 hogsheads, worth at £2 a hogshead £96,750. The pot fruit at sixty bushels to the acre and 3s. a bushel—a very low price—will be worth £48,375. It must also be remembered that pot fruit is grown in almost every garden, and this, if estimated at the same value and quantity as that grown in orchards, will yield £48,375, and thus we arrive at the large sum of £193,500, the total value of the Apples grown in the county.

"If, then, these calculations are correct the £21,500 acres of orcharding in Herefordshire should return, taking one year with another, with ordinary care more than £6 an acre, without reckoning the value of the underneath crop. We know that it is not uncommon for orchards to return £10 per acre.

Fig. 12.—*Erica Lindleyana* (see page 91).

"To this day cider is generally made, as it was centuries ago, by the labourers on the farm, with a minimum of care, labour, and superintendence. Most of the details, such as the selection, growth, preparation, and crushing of the fruit, seem in a theoretical view to be each of them capable of improvement. Almost the first consideration in the culture of the Apple is the selection of sorts to the purpose for which they are required, whether it be the mill, the kitchen, or dessert.

"With the view of aiding the grower in making a selection the Woolhope Club have decided on publishing a Pomona, in which every Apple and Pear worthy of cultivation for acknowledged good qualities, such as productiveness, hardness, flavour, sweetness, &c., will be described, and its outline or coloured representation given. Dr. Hogg, the well-known pomologist, has kindly offered to edit the work for our Club, and thus the accuracy and care with which it will be produced are amply guaranteed."

THE HAWKHURST HORTICULTURAL SOCIETY.

THE annual Show of this Society is deservedly very popular, and that recently held in the grounds of Lady Thompson, Fairview, was as usual a complete success. The Society was originally formed with the creditable motive of improving cottagers in gardening generally, and the Committee deserve much credit for still bearing this in mind. The district includes several large parishes situated in a delightful and very fertile part of Kent. A visit to this and other similar shows in Kent and Sussex would astonish

many frequenters of flower shows, the cottagers exhibiting in such numbers and staging such excellent produce. It is impossible to estimate the amount of good this and kindred societies do among the industrial classes, as none but those mixing with them know how much they anticipate the Show, and what pains is taken with the intended exhibits.

The cottagers' exhibits alone, however, are not sufficient attraction to "the million," consequently the aid of the professional gardener must be solicited. To these also fair encouragement in the shape of prizes must be offered, as exhibiting entails much hard work, known only to them who have experienced it, and there is nothing strange in the fact that gardeners require to be paid for their labour. Competition has effected a marked improvement in the professional classes around Hawkhurst, thus proving that employers who subscribe to horticultural societies are indirectly repaid by the improvement effected by the societies in their own gardens. Committees may be hardworking and practical, but without funds are powerless to do good. The following is a list of some of the principal prizewinners in the professional classes.

In the open classes Mr. Gilbert, Springfield Nurseries, Hastings, was first for stove and greenhouse plants in flower, and also for foliage plants. His collection included very fine plants of the popular but old *Kalosanthes coccinea*, *Allamanda Hendersonii*, &c. Mr. L. Barnes, gardener to E. B. Sutton, Esq., Copt Hall, Hawkhurst, was a very successful exhibitor, being first for Achimenes, Coleuses, Pelargoniums, twelve Roses, collection of fruit, collection of vegetables, white Grapes, &c. Mr. Manck-tellow, gardener to Dr. Harris, Northiam, was first for four stove and greenhouse plants, six Ferns, &c. Mr. Nicholls, gardener to J. C. Fisher, Esq., Hawkhurst, was first for Fuchsias, foliage plants, &c. Mr. Hodgkins, gardener to Capt. Oakes, Sandhurst, was first for Caladiums, Gloxinias, &c. Mr. G. Rummery, gardener to Mrs. Gow Stewart, was first for a green-fleshed Melon, &c. Mr. Gilmour, gardener to the Rt. Hon. G. J. Goschen, M.P., was first for Balsams, Cucumbers, &c. Mr. W. Salcombe, gardener to Dr. Newington, Ticehurst, was first for Roses (special prize given by Mr. W. Knight, Hailsham), collection of fruit, &c. Mr. F. Deane, gardener to T. Neve, Esq., Cranbrook, was first for bouquet. Mr. J. Iggulden, gardener to Rev. Canon Jeffreys, Hawkhurst, was first for a collection of Vegetables. Mr. Whitby, gardener to E. Hardcastle, Esq., M.P., Hawkhurst; Mr. Butler, gardener to D. N. Olney, Esq., Robertsbridge; Mr. W. Brett, gardener to G. French, Esq., Hawkhurst; Mr. Willard, gardener to J. A. Jackson, Esq., Hawkhurst; and Mr. Bishop, gardener to W. Harner, Esq., Hawkhurst, were also successful exhibitors. The cottagers exhibited in great numbers, there being fifty prizewinners, some of them taking several prizes.

Mr. W. Potten, nurseryman, Sissinghurst, staged an excellent collection of plants not for competition, and Mr. Knight, nurseryman, Hailsham, some very good stands of Roses of the best sorts. There was also a tent given up to the arts and manufactures, which included a variety of useful and valuable ornamental articles which helped to make the Show very attractive and enjoyable.

JUDGING.

WHILE agreeing in the main with the observations in last week's Journal, will you allow me as one who has had some experience to supplement them with a few remarks? In the first place I hardly think that the definition blindfold and open judging is a correct one; for the system which you have described as that adopted by the Royal Horticultural Society and others is, or ought to be, as much a blindfolded one as any other—that is, the card itself is no indication of who the exhibitor is; the number indeed may be noted, and so if it occurs in other classes the exhibitor may be guessed at. What I call open judging is the system adopted, amongst others, by the National Aricula Society, where the name of the exhibitor is exposed to view; and although this has been objected to, yet I am convinced that as true and correct judging is given in such instances as in others. As you justly observe, an experienced judge knows from the very setting-up of the blooms, the writing, the character and quality of the plants or blooms, or something, to whom they belong, but he is unworthy of the position if any of these things influence him.

I remember a ludicrous case of the insufficiency of any of these safeguards. I was once called upon to judge at a provincial Rose show where a very large prize was offered for the best seventy-two Roses. A most elaborate system for blind-folding the judges had been arranged, and it was thought most successfully. After my colleague and myself had gone round and adjudged the prizes I said to the Secretary who accompanied us, "That box is So-and-so's;" in fact we named every competing box, in some of the cases one Rose was sufficient to determine it. And there, and in every instance where I

have had the opportunity, I have succeeded in inducing them to adopt the far simpler plan in use in London.

Again, I would observe that these attempts to prevent the judges knowing the exhibitors is not intended by the promoters of a flower show to show that they in any way mistrust the judges, but because of the petty jealousy of some of the local exhibitors, generally small gardeners, who, not being particularly gifted with clear eyesight themselves, are sure, if they are beaten, to lay it on the judge. Where a judge has twenty plates of Longpod Beans to decide upon, at least thirteen out of those who are beaten think they had no business to be left out in the cold, and probably there is very little difference between their Beans and those that take the prizes, and one can understand how some persons would storm if the exhibitor's name was exposed. Persons of this class are one of the greatest hindrances to local shows, and unfortunately they are proof against all explanation. For example, at a show at which I was judging the other day a mistake had been made by the Secretary in putting two exhibits in the same class, whereas they ought to have been in different classes. After the adjudication was made attention was directed to this, and it was necessary to alter. The erring card had to be torn up, and the wrathful exhibitor went storming through the place, "I seed him tor' it up myself," evidently coupling that act with his loss of a prize; if it had not been "tor' up" he would have been all right. On the whole I believe the system of the Royal Horticultural Society, National Rose Society, &c., is that which works best, and I believe it will be ultimately adopted throughout the country. As the advertisements say, "it only needs to be known to be appreciated."—D., Deal.

FUCHSIAS FOR AMATEURS.

IN a former communication I referred to the great importance of good soil as a first essential in plant culture, and to the wisdom and even the economy of purchasing it if a supply cannot be had by other means. But soil, I wish to repeat, is not everything. Some cultivators, even if they have the best compost that can be mixed, do not succeed so well as others with soil of a very ordinary nature. The difference lies in the treatment of the soil and the plants. Ordinarily light and fertile garden soil will grow Fuchsias fairly well provided the plants have correct treatment in other respects. If anyone doubts this let him plant out a Fuchsia anywhere in his garden in which he can grow good Radishes in July, water it as needed, and he will be surprised how well the plant will flourish.

For growing plants in pots mix a twentieth part of soot and a tenth of silver sand with fertile garden soil, and in this compost the plants will grow. If the garden soil is heavy a sixth of cocoa-nut fibre refuse will be an advantage. This compost is suggested for those who cannot obtain turfy loam, leaf soil, &c.

A few errors that amateurs not infrequently commit in Fuchsia culture is—first, starting their plants too soon in spring when they have not light and well-ventilated houses for growing them on in a sturdy short-jointed manner; secondly, by allowing the wood to become hard and brittle when the plants are small; and thirdly, permitting them to become infested by insects, rendering fumigation or the application of an insecticide necessary.

If a Fuchsia becomes root-bound in a small pot its wood ripens prematurely, it flowers early, becomes exhausted, ekes out a miserable existence, but never makes a good plant. The growth must be kept in a soft state until the plant has attained the desired size for flowering, or really satisfactory results cannot be produced. If a plant is kept in a sunny window, or under the shade of Vines during the summer, or is unduly crowded by other plants under glass, it cannot prosper. It must be kept growing steadily, it must be kept short-jointed, it must be kept clean.

These conditions are easily attained at this period of the year if the mode of attaining them is not considered too simple for adoption. Place them on ashes on a shaded border, such as behind a north wall; water them well, keeping the ground on which the pots stand constantly moist, sprinkling the foliage well during sultry weather, and they will grow more healthily than in any house. Plants large or small are better outdoors than in during the next six weeks or two months, unless they have houses or frames specially adapted for them, which is seldom the case with amateurs.

Fuchsias obtained from a nursery now are usually much

stronger for the money than when purchased in early spring, and they are now most easy of management, should flower in the autumn, and lay the foundation for good plants another year.

Unfortunately the varieties having the finest individual flowers are not always the best worth purchasing, as many of the newer sorts do not possess good habits and constitutions. Some of the old and moderately old sorts are still the most satisfactory; for instance, there are few freer growing and flowering Fuchsias in cultivation than the good old Rose of Castile. Another old variety, Venus de Medici, is still one of the most attractive of the light sorts. A fine, free, and valuable variety is Miss Marshall; Starlight is also free and very good; and highly effective is Lady Heytesbury. Arabella Improved is a strong grower with fine bells; and a little gem is Guiding Star. Marginata is also a real amateur's Fuchsia in this section. Mrs. J. Lye is also good; and distinct and pleasing is Minnie Banks. Lustre is a strong grower, and Beumanni, dwarf, make up a dozen good varieties having white tubes and corollas and pink or violet corollas.

Amongst the dark varieties the following are free growers and bloomers, and altogether good:—Model, Albert Victor, Enoch Arden, Try-me-Oh, Rhoderic Dhu, La Traviata, Killiecrankie, Noblesse, Wave of Life, Victor Emmanuel, Crown Prince of Prussia, Lord Falmouth, and to make a baker's dozen, the good old Souvenir de Chiswick. The dark varieties with double corollas are mostly of straggling growth; Blue Boy, however, is dwarf, and so are Little Bobby and Alberta. Good stronger growers are Avalanche, Albert Memorial, and King of the Doubles; large but almost ugly is Champion of the World. Amongst the double varieties with white corollas the best are Mrs. Cannell, Miss Lucy Finnis, Little Alice, and Enchantress. Singles of the same colour are Conspicua, old but good; Cannell's Gem, Miss Burdett Coutts, and Mrs. Mein.

All of the above I have grown and can recommend, also two others of recent introduction, and quite distinct from all the varieties named—namely, Mr. Laing's useful hybrid Earl of Beaconsfield, and a variety sent out by Mr. Cannell named Aurora superba.—A NORTHERN GARDENER.

STIRLING CASTLE APPLE.

MR. WILLIAM HARVEY, watchmaker, told me that it was raised about fifty years ago by a man of the name of Christie, who kept a toy shop, and had a garden off the back street (i.e., Spital or John Streets) where he experimented on the raising of seedling Apples, but Stirling Castle was the best of them. The first graft was given to a gentleman of the name of Anderson, and planted in his garden in Albert Place, now occupied by his daughter, Mrs. Watt.—G. McDUGALL, *Rapallock, Stirling, N.B.*

NAN-MU TREE OF THE CHINESE.

DR. BRANDIS has drawn our attention to a passage in Mr. Davenport's report on Yunnan (Parliamentary Papers, China, No. 2, 1877, p. 13), giving an account of the Nan-mu tree, the wood of which is so highly valued by the Chinese. If it could be accurately identified the cultivation of the tree would no doubt be very profitable in India, and I therefore place on record what has been ascertained respecting it. The following is from Mr. Davenport's report:—

"This part of Yunnan, which seems to be between 25° and 26° N. lat., produces the famous Nan-mu, so highly esteemed by the Court for building purposes and by the wealthy for coffins on account of its durability. This timber is to be seen in perfect condition after the lapse of nearly three centuries in the shape of enormous pillars in the tombs of the emperors of the Ming dynasty, and has usually been supposed by foreigners to be teak. The tree is tall, thin, straight-growing, having no bough or twigs on the stem but suddenly shooting out branches at the top, somewhat like a canopy over a may-pole. Its bark is of a peculiar ashy grey colour, and a specimen of the leaves gathered by myself, accompanying this report, will prove beyond all doubt that it is not a member of the teak family. During the Ming dynasty this wood had already become scarce (having probably been everywhere cut down and not replanted), and was brought chiefly from almost inaccessible valleys situated in the valleys inhabited by wild tribes. The imperial palaces at Peking were built almost entirely of this timber.

"At the present time this wood is imported into Shanghai in planks measuring 8 feet long by 13 or 14 inches in diameter, for which the highest price is 200 dollars per plank. Whole coffins range from 100 to 800 dollars. The quality is judged of chiefly by the pungency of the scent."

The leaves sent by Mr. Davenport to the Foreign Office cannot now be traced, but by the courtesy of E. Bradford, Esq., late Master of the Apothecaries Society, to which the specimens of drugs collected by Mr. Davenport were sent, I have been favoured with a further fragmentary specimen transmitted by Mr. Davenport, and also with specimens of the wood brought to this country by Wm. Lockhart, Esq., who states that "it is also used largely by Chinese gentlemen who take a pride in their libraries to make boxes for sets of volumes, and also to place between sets of volumes."

The leaves are too slender a basis for a certain botanical determination in the absence of flowers and fruits; but it appears extremely probable that the tree belongs to the family Lauraceæ, and the leaves themselves agree very closely with those of *Phoebe pallida*, Nees.—(*Kew Report*.)

SUMMER CUCUMBER CULTURE.

"NEW SUBSCRIBER" says that for the first time the Cucumbers in the district in which he resides are badly attacked by what to him and his neighbours is a new disease, but which from his description is evidently a bad case of *gumming*, so called from the sap which exudes from the affected fruit, and becomes hardened to the consistency of gum along the numerous cracks on its surface.

There is no cure for this complaint, and the plants must be destroyed—not by any means in despair, for a fresh batch of seedling plants should be planted immediately in fresh sweet soil, and although they may be grown in the same house or pit yet they may not have a single fruit affected.

Another correspondent complains that his plants, notwithstanding the advantage of a good house, have died after "bearing a good many Cucumbers." This is probably a case of exhaustion—I say probably, because grubs may have attacked the roots and induced premature decay. Barrenness and decay are, however, so frequently caused by ignorance of the treatment which the plants should have when in full bearing, that attention must again be called to the palpable fact of such a gross-feeding plant requiring supplies of nutriment in proportion to its size and crop of fruit. Not only must there be frequent surface dressings of fresh soil, but that soil must be of such a nature and so disposed as never to become a sodden compact inert mass from the daily drenchings of water and liquid manure which the plant requires and must have to enable it to perfect its fruit, and at the same time make abundant new, robust, and fruitful growth.

If I were asked for a method of growing Cucumbers in summer which had never been known to fail I would say, Take a table, place it under and some 3 feet below a glass roof; take a bushel of soil consisting of chopped turf and decayed manure in equal parts, shoot it on the table in a heap; in this plant your Cucumber plant, train it up a stake to a wire trellis strained a foot below the roof, nip off the top of the leading shoot when it reaches the trellis to induce a stout lateral growth, which train about the trellis. Water and syringe freely, and when the roots appear outside the heap of soil cover the mound with a couple of layers of turf sods, and go on adding more sods whenever the roots peer out and ask you for them. As the fruit begins swelling substitute sewage or liquid manure for the clear water, and in the latter stages of the plant's existence cover the entire heap of soil with cow dung.

My motive for naming a table for the soil is to make it clear to everybody that no hotbed, manure heap, or bottom heat of any kind is wanted for summer Cucumbers. A stage or floor would answer equally well, provided there is a free drainage for superfluous water. Plenty of fresh air, turf sods, liquid manure, cleanliness, prompt and thorough drainage, and painstaking are therefore the few and simple elements of success. Avoid deep pits or trenches. Avoid heavy or very fine soil; if you cannot procure turf mix a lot of broken bricks, mortar rubbish, and charcoal with some of your best garden soil. When the plant is in full growth pour on sewage by the gallon till it streams out of the bottom of the heap, and above all remove the fruit as soon as possible after it is fit for table. A dozen or two of full-grown fruit hanging upon a plant at once makes an immense strain upon its system, and if left on long exhaustion is pretty certain to follow, of which the effects will

be visible either in barrenness or in abortive fruit—curled, attenuated, and worthless.—EDWARD LUCKHURST.

CAPE HEATHS.—No. 7.

JULY.

If our readers have followed the instructions previously given and have used ordinary care in carrying them out their *Ericas* will now be forming bushy heads, for, although generally looked upon as slow-growing plants, they rapidly assume handsome proportions after about the third year. It will be well to set the plants in the open air now—that is, if they are not already removed from frames or pits, as by this system the growths become thoroughly hardened and vigorous.

Fig. 13.—*Erica Shannoniana*.

Care must be taken to water only during early morning or towards evening, as continual watering during the heat of the mid-day sun is sure to result in death to the plants, and yet we have seen this practice persevered in by men who consider themselves skilful plant-growers. When water is given let it be in such quantities that the whole ball of earth becomes saturated, for partial watering, we are assured by practice, is a fertile source of mildew. Again, do not place Heaths under the shade of trees: they do not require it, and often become injured by drip during a few days' continued rain, and their growth only becomes partially ripened. Soft or rain water should be used for watering these plants. If during drought this is not procurable the water to be used in the evening should stand fully exposed to the sun during the whole day. Some recommend the use of weak liquid manure for *Ericas*, and we have seen it applied beneficially to plants that are not wanted after the blooming season; but it should never be given if the plants are intended to live a number of years. The following kinds will be found a good selection for effect during July.

Erica ferruginea superba.—Leaves arranged in fours, linear obtuse, densely clothed on the edges with long, woolly, rusty hairs. Flowers in spreading whorls from the ends of the principal branches, cylindrical, with a swollen base and con-

tracted mouth; limb rather small, spreading; colour light pink at the base, passing upwards into a reddish purple.

E. Shannoniana (fig. 13).—This is a superb large-flowering species, bold in growth, and much-branched. Leaves arranged in threes, ascending, three-sided, and acuminate. Flowers produced in large terminal whorls; these are flask-shaped, delicate pink or flesh colour, saving at the contraction of the neck, where the colour is more intense; footstalks and calyx deep red; whole flower glutinous.

E. hyacinthoides.—A dwarf-growing, neat, and handsome species, now unfortunately very rare. The last time we saw it was in the gardens of Harrenhausen in Hanover, where so many of these beautiful old species were treasured up by the elder Wendland. It scarcely reaches 12 inches in height, much-branched, and densely furnished with stout, smooth, and shining dark green linear obtuse leaves. Flowers large and freely produced from the ends of nearly all the branches. They are arranged in fours, flask-shaped, the segments being large and spreading, whilst the colour is a beautiful soft rose throughout.

E. infundibuliformis.—A slender-growing, beautiful plant. Leaves linear obtuse, smooth, arranged in threes, and light green. Flowers erect, long, and slender, produced in fours upon short footstalks; tubes deep red, the broad spreading limb being white.

E. verticillata.—This is an elegant and extremely useful plant for all purposes; it is erect in growth. Leaves arranged in fours, linear acute, destitute of hairs, and dark green. Flowers produced in large pendant whorls towards the ends of the branches; they are about an inch long, cylindrical, somewhat square at the base, and brilliant orange red in colour.

E. jasminiflora.—Although somewhat straggling in habit this is, nevertheless, a very desirable species. The leaves are mostly arranged in threes, triangular, spreading, and dark green. Flowers mostly in threes from the ends of the simple branches, about 1½ inch long, cylindrical, with a swollen base, and a large, flat, spreading limb, the segments of which are cordate; tube rosy pink, the segments pure white.

E. incarnata.—A species now very seldom seen in collections, yet it is a small and compact grower, and very gay when in flower. It forms a dense much-branched plant some 12 or 18 inches high, the leaves being linear obtuse, quite smooth, arranged in fours and bright green. The flowers are produced in dense bunches upon the ends of all the branches, they are ovate with a contracted mouth; colour bright reddish pink.

E. vestita alba.—A rather tall-growing kind. Branches ascending. Leaves about an inch long, crowded, linear, arranged in sixes, and dark green. Flowers produced in large whorls near the ends of the branches, sometimes in double tiers. Flowers longer than the leaves, pure white, slightly downy.

E. vestita lutea.—Similar in habit to the preceding, but the leaves are more robust. Flowers produced in large and dense whorls; they are club-shaped, upwards of an inch long, slightly ribbed, and clear sulphur yellow in colour.

E. vestita fulgida.—A very highly coloured variety of robust growth. Branches erect. Leaves long, arranged in sixes, linear, smooth, and dark green. Flowers crowded near the apex of the principal shoots, upwards of an inch long, and rich bright red.

E. vestita incarnata.—This is scarcely such a strong-growing variety as the preceding. Leaves six to eight in a whorl, linear, erect, and very deep green. Flowers produced many together in crowded whorls near the apex of the main shoots; they are club-shaped; about an inch long; ground colour white suffused towards the apex with bright rose or flesh colour, rendering it a very charming plant.

E. vestita rosca.—Erect in growth, with simple branches and dark green leaves, which are linear obtuse, arranged in eights, and shorter than either of those varieties named above. Flowers crowded, an inch in length, and rich deep rosy colour.

E. vestita carnea.—A truly beautiful variety. Habit of growth erect as in the other kinds. Leaves linear, erect, slender, and pale green in colour. Flowers produced in crowded whorls towards the upper part of the branches, about an inch in length, and of a delicate flesh colour.

E. Irbyana.—The improved form of this species produced by the Messrs. Rollisson & Sons of Tooting is a most desirable variety. It produces long, simple, erect branches. Leaves somewhat triangular, armed at the point with a stiff bristle, the edges slightly toothed; colour deep green. Flowers in

large spreading umbels, upon long footstalks from the ends of the branches; they are upwards of an inch long, much swollen at the base, very sticky; the segments heart-shaped and spreading, white, tinged with flesh colour at the base.

E. Lindleyana (see fig. 12, page 87).—Leaves arranged mostly in fours, linear oblong, mucronate, ciliate on the edges, deep green, with a central white stripe on the back of each leaf; whorls large and terminal, tubular, deep crimson passing into white; the throat and limb vivid green.

E. Jubana.—A beautiful free-flowering plant, and of compact habit. Leaves in threes, flat on the upper side, keeled below, and dark green. Flowers produced upon very long, erect, red footstalks, in large umbels; they are much swollen at the base, with a contracted mouth and large spreading limb; the latter is white, whilst the tube is reddish purple.

Fig. 14.—*Erica ampullacea*.

E. droseroides.—An elegant species now but too seldom seen. It is a dwarf much-branched plant. Leaves alternate, linear obtuse, with recurved points, the edges densely furnished with glandular hairs. Flowers produced in large whorls upon the ends of the branches. These are reddish purple in colour, much swollen at the base with a contracted neck; segments somewhat small, spreading, and deep red; whole flower glutinous.

E. nitida.—A free-growing, densely branched plant of great beauty. Leaves in threes, short, linear obtuse, and deep green. Flowers somewhat ovate, terminal on all the small branches, in umbels of three to five, forming spikes 9 to 12 inches long; footstalks, calyx, and the whole of the flower beautiful snow white.

E. Coventryana.—This is a compact, low-growing, and much-branched plant. Leaves in fours, linear obtuse, bright green. Flowers stemless, and set in large clusters among the foliage on the ends of the branches; the tube is bright red, the spreading segments of the limb pure white.

E. ampullacea (fig. 14).—Our figure represents the typical plant, which is very beautiful; the ground colour is white or pale flesh, striped throughout with deep rose, the contracted neck being deep purple. In addition to this form the Messrs. Rollisson & Sons, who have done so much towards the improvement of this class of plants, have produced and sent into com-

merce three varieties—viz., *ampullacea elegans*, *ampullacea obbata*, and *ampullacea rubra*, all of which either in colour or size are great improvements and should be looked after by lovers of *Ericas*.

E. metulæflora superba.—This improved form of the species is much easier to grow than the normal form through not being so liable to mildew. Leaves in fours, linear obtuse, slightly hairy on the edges. Flowers in terminal whorls, wholly deep reddish crimson, saving the circle round the throat, which is deep purple.

E. obbata exposita.—This is a very grand variety, the result of much labour and care. It originated in the Tooting Nurseries, and has been put into commerce this spring for the first time. Leaves mostly in fours. Branches slender, bearing large terminal whorls of very large flowers, which are much swollen at the base and pure white. Limb large and spreading, and also pure white. These flowers retain their beauty and purity of colour a very long time, as they are entirely destitute of the gummy secretion which is so characteristic of the hardwood *Ericas*, and which soon renders them dull, and in the neighbourhood of towns oftentimes very unsightly.

E. Dennisoniana.—This is another of the Messrs. Rollisson and Sons' gumless seedlings which cannot be too highly recommended. Leaves arranged in threes, linear obtuse, dark green on both surfaces. Flowers produced in terminal whorls and much swollen at the base, where they are tinged with carmine, the rest of the flower pure white; limb large and spreading.

E. venosa.—Leaves arranged in fours, linear obtuse, slightly reflexed, dark green. Flowers much swollen throughout, colour rosy crimson; segments of limb white.

E. tricolor profusa.—A superb variety, and another of the Tooting seedlings. It is very compact in habit, and an abundant bloomer. Leaves arranged in fours, linear obtuse, mucronate, and densely fringed with long hairs at the edges; colour deep green. Flowers terminate the branches, produced in whorls of great size; they are large and tubular, with a swollen base, colour deep rich rosy carmine passing into white, the contracted neck being encircled with green, whilst the tips of the segments are white.

E. Fairrieana.—A slender branching kind of great beauty. Leaves arranged in fours, linear, mucronate, and fringed with short hairs at the edges, green above, with a central pale band on the under side. Flowers large, in terminal whorls of from eight to twelve, much swollen at the base, where the colour is rosy carmine, passing upwards into pink, the contracted neck deep crimson; limb reflexed, pinkish white.

E. insignis.—A bold-growing kind and a profuse bloomer. Leaves arranged in fives, oblong obtuse, fringed with hairs on the edges and pale green. Flowers in large terminal whorls, somewhat short, but stout; colour dark rosy carmine at the base, contracted throat, dark purple; segments of the limb white.

NOTES AND GLEANINGS.

WE are informed that the principal feature of next Tuesday's FLORAL MEETING at the Royal Horticultural Society will be a fine display of Tuberous Begonias in flower from Chiswick and some of the leading nurserymen.

—AT the present time there is nothing more beautiful in Battersea Park than *YUCCA FILAMENTOSA*. Plants of this free-flowering *Yucca* at "Alpine Point" (which is this year more attractive than ever), also on the elevated ground near the artificial rocks, attract the attention of all visitors. The Swamp Lily of North America has recently been flowering grandly in a pot plunged in a swamp on the lawn; from this pot were twenty flowering stems bearing in the aggregate nearly two hundred flowers. It is the finest example of this beautiful Lily that has come under our notice. The Tree and other exotic Ferns and tropical plants, and the well-filled carpet beds have now crowds of admirers, and the Park altogether, which will soon be at the zenith of its beauty, has never looked better, if so well, as during the present summer.

—“W. J. M., *Clonmel*,” writes to say he has just been shown a *CONE OF THE ARAUCARIA* or Chili Pine by Mr. Sheeley, head gardener to Miss Malcomson, Melview, near that town, which is perfectly globular and covered with prickly scales, and weighs about 3 lbs. It was produced by a tree estimated at forty years old, and never produced one before. When trees commence coning they usually continue producing seeds. Plants of the *Araucaria* have been raised from seed produced

in this country, and probably the cone referred to contains fertile seeds.

— **APPROPOS OF JUDGING AT EXHIBITIONS** the Rev. C. C. Ellison has sent us a leaf from a book that was handed to him as a Judge at the Caythorpe Flower Show, and which is the invention of Mr. Palmer, the Secretary of that Show. Two-thirds of the leaf constitute a prize card that is torn from the counterfoil and placed on the exhibits when the prize is awarded. The judge holds the book and writes the winning number on the prize card and counterfoil, an assistant writing the name of the exhibitor on the space provided therefor on the card severed from the book. As observed by Mr. Ellison, mistake is impossible, as if the card were removed the counterfoil would show the winner. Where judging is done under number, as is the case at many local shows, the Caythorpe plan is simple and expeditious. The card is, however, too small for large exhibitions, and space for the names and addresses of both owner and gardener is not provided.

— **A VERY** prolific and close-growing FIG may now be seen in Messrs. Osborn's Fulham Nurseries. It is now being sent out under the name of **OSBORN'S PROLIFIC**, an appropriate name, for plants growing in small 32-sized pots and looking remarkably strong and healthy are bearing five and six fruit each, besides showing a dozen others as a succeeding crop. Vines in pots, too, are looking extremely well, and are ripening their strong canes rapidly.

— **MR. ADDISON** says that he saw a quantity of the **JAMES VEITCH** variety of **STRAWBERRY** at the Show in Edinburgh on the 10th ult., sent from Mr. Dunn, Dalkeith Park, and they far surpassed in size any he had ever seen. Mr. Dunn writes that it is a first-class sort. He gathered some fruits 3 ozs. and 3½ ozs. in weight.

— **A BRENCHEY** correspondent has sent us an example of **ABNORMAL GROWTH IN THE POTATO**. The stem, which is stout, not only contains tubers at the axil of every leaf, but even the flower stalk is surmounted with a small aerial tuber from which a cluster of malformed flower buds issue. We have often seen tubers produced by the stem above ground instead of on that portion below the surface, but never in such a marked manner as in the example before us. It illustrates in a practical manner the fact that the tubers are really an integral part of the stem of the plant, but we cannot account for their formation in the air instead of in the earth. Probably the plant has received a check by some cause or other during its early stages of growth. No tubers formed in the soil, but the whole crop is borne by the stem. Some of them are of good planting size and shall be planted. A portion of plant bearing aerial tubers has also been sent to us from Itchingfield Rectory, Horsham.

— **MR. MURRAY**, the head gardener at Peniarth, and the under gardener, on Saturday last found a plant of the tropical Fern, **PLATYCEBIUM ALICORNE**, growing upon the Cader Idris range of mountains in Wales. Some years since persons from the gardens of Penrhyn Castle discovered the same Fern at Llyn Idwal, and we understand that it was also found upon the estate of a nobleman in the north of England. The plant recently discovered is a young one, and has been brought to Peniarth in good condition.

— **THE NE PLUS MEURIS PEAR**, writes a practical gardener, is very prolific this season. To have it in perfection the fruit ought to be freely thinned, for being produced in great clusters unless well thinned it is comparatively useless. All kinds of Pears are improved by judicious thinning, but none more so than the Ne Plus Meuris, the core being so large that small fruit may be said to consist of little but core and skin, and in this state are certainly not fit for the table. A good dish of this variety in January and later is sometimes very useful.

— **A CORRESPONDENT**, "E. H.," desires to know where **CHIPPED GRANITE** or **MARBLE** can be obtained for forming garden paths. We shall be glad if any of our readers can supply the information.

— **DWARF KIDNEY BEANS** are again very prolific, one grower near Grays, Essex, having already sent upwards of four hundred sieves to the London markets. The Scarlet Runners, where liberal treatment was given in the first instance, are bearing freely, but the late extremely hot and dry weather has proved more prejudicial to them than to the dwarfs. The genial showers now falling will soon have the effect of stocking the markets, and it is to be hoped they will realise more remunerative prices than has lately been the case

with Peas. With the latter the prices have been so low that many growers gave up picking, the prices obtained not paying for the labour. The supply of vegetables at present apparently altogether exceeds the demand, and the growers are consequently having a bad time of it.

— **WE** learn that the Show of the **ROYAL HORTICULTURAL SOCIETY OF ABERDEEN**, held on the 25th ult., was both extensive and excellent. Mr. Roberts, gardener to John Laing, Esq., Granton Lodge; Mr. Forrest, gardener, Haddo House; and Mr. Middleton, gardener, Balgownie Lodge, secured the prizes in the specimen plant classes with admirable examples of culture. Ferns were remarkably well staged by Mr. Hadden, gardener, Denmore; and Mr. Grigor, gardener, Sunny Bank, who were awarded the chief prizes, and other cultivators. Roses were good, the silver cup for twenty-four blooms being won by Messrs. Cocker & Sons. Fruit was well represented, the first prize for a collection being secured by Mr. Farquhar, gardener to Col. Gordon of Fyvie for superior produce. The chief prizes for Grapes were won by Mr. Ogg, gardener to Sir W. Forbes, Bart., Fintray House; Mr. Farquhar; and Mr. Proctor, gardener, Slains Castle, who all staged good and well-finished bunches. For the largest Strawberries, a dish of fifty, the first prize was awarded to G. J. R. Gordon, Esq., Ellon Castle (Mr. Wilson, gardener), for Eclipse, immense cockscomb-shaped fruit. For four dishes the first prize was awarded to Mr. J. Mortimer, Rubislaw, for President, Myatt's Seedling, Sir Joseph Paxton, and Oscar. Vegetables were of splendid quality and in great abundance, the first prize for a collection of ten kinds going to Mr. Ogg. The Show was well managed by Mr. Rennie, the Society's able Secretary.

— **RIPENING OF GRAPES AFTER REMOVAL FROM THE VINE**.—In the *Gazetta chimica Italiana* some experiments by M. Pollacci are described, in which he finds that the process of ripening continues for a certain time after the Grape has been removed from the parent plant. The bunches of fruit removed were, as far as possible, equally divided, and the quantity of glucose and acid determined in the freshly gathered Grapes, as also in portions kept in the shade for some ten or twelve days. In all the portions which had been kept the glucose had increased, whilst the amount of acid had diminished, showing that a certain amount of ripening action had taken place; this action, however, ceases after a time, the ripening never attaining full maturity.

FRUIT IN THE UNITED STATES.

THE last issue of "Scribner's Monthly" contains an interesting account of a new American industry. The extraordinary fecundity of the United States in the matter of fruit is proverbial, but it may not be generally known that three million Peach trees bloom every spring on the sunny plains between the Delaware and Chesapeake Bays. The details of the American fruit crop almost savour of romance. The Apple crop of that country is past counting; the surplus fruit, if properly saved, would keep all Europe in table luxuries. The birds on New Hampshire hills are feasted with Raspberries, the mountains of North Carolina and Tennessee are purple with Blackberries which go to waste, and the time has been when an extra good crop of Peaches in Delaware has meant a million baskets of fruit untouched upon the trees. For many years there was a great waste of fruit in the States, but by a process now adopted a large per-centage of the growth is saved and rendered useful.

Several of the States now produce sliced dried Apples and Peaches, delicately coloured from light straw to pale flesh colour. In Tennessee, North Carolina, and Georgia are to be seen at the farmsteads rows of boards tilted up to the sun and covered with sliced fruits. The first improvement in drying fruit consisted of covering it with glass. The fruit was put beneath sashes, in which holes were cut to produce a current of air; the fruit was spread on trays in the full sunlight, and the glass kept out the rain, birds, and insects. Stoves succeeded to sashes, and then came drying closets. But best of all is a portable iron stove or drying machine, costing about \$70, and serving to dry all kinds of fruit in a better manner than the wooden stoves. "A fire is kept up in the fire-box at the base, and above it are moveable shelves for Apples, Peaches, berries, corn, Grapes, or other fruits or vegetables. A constant stream of hot air passes through the apparatus, sweeping across the trays of fruit, and quickly extracting all their moisture."

In the level peninsula between Chesapeake Bay and the Delaware Peach trees stand in rows a mile long, luxuriating

in a warm and mellow soil and a genial climate. There are forests of twenty thousand trees standing in firm and stately lines. A little has been done in the way of exporting dried fruits to England and Europe, but judging from her unparalleled yearly riches America might do much more in this direction.

FOSTER & PEARSON'S PATENT SLOT THROTTLE VALVE.

WE direct attention to the above valve, which is adapted to all the purposes for which the ordinary throttle valve is now used in regulating the flow of water, steam, gas, &c. The following are among its advantages:—The working parts of the valve can be readily removed and repaired without disturbing the body of the valve. The valve seat in which the brass wing works forms part of the valve, and has not to be removed, thus reducing the size of the joint of the cap or cover materially, and lessening the chance of an unsound leaky

Fig. 15.—Foster & Pearson's Patent Slot Throttle Valve.

A, Valve socket. B, Moveable cap. C, Indiarubber ring for rendering the valve secure.

joint when refixed. The valve cap or cover is secured by two screws in the top of the valve, and can be easily removed in any position in which the valve handle can be reached. The importance of this will at once be seen in the case of valves fixed under the floors of buildings and in other positions where it is difficult to get at the sides or bottom of the valve.

A frequent cause of damage to throttle valves is their being turned the wrong way by those who have charge of them. This is prevented in the valve under notice by means of a small pin working in the collar of the valve spindle, which renders it impossible to turn the valve wing past the centre when opening it.

NOTES ON VILLA AND SUBURBAN GARDENING.

A FORTNIGHT or more of tropical sunshine has afforded everyone a chance of destroying the numerous weeds which only a few weeks since were a great trouble in every garden, and if the hoe has been busily engaged none ought now to be remaining. Within the last few days rain has fallen in several localities, which was much needed; the excessive heat was beginning to be felt on light soils, while on heavy land the surface had become so baked that it was with great difficulty that a spade or a fork could break it.

Fruit trees on walls require going over, and to have the shoots secured to the wall, stopping any foreright or gross shoots. Gross wood in Peach or Nectarines is not wanted, and where any growths are taking the lead nip the points out, which will not only stop their progress, but will disperse the flow of sap regularly throughout the weaker-growing shoots. Water liberally all trees on walls, plying the garden engine frequently over the foliage in the evenings after hot days. Thin any crops that are too heavily set, and expose the fruit as much as possible to the sun, to gain both colour and flavour. Net Morello Cherries, both standards and those growing on walls, for the fruit will be useful for many weeks to come. Those trees growing on walls are most easily protected from birds; merely fastening the nets at the sides and ends, and placing a few forked short sticks at intervals throughout the entire length, will enable the nets to project a sufficient distance

to puzzle the most artful of birds from getting their bills through to peck the fruit. Standard or bush Cherry trees are not so easily and effectually netted, and great pains must be taken to make every connection secure, or blackbirds and thrushes are almost certain to disturb the nets sufficiently to make an entrance. These birds are most partial to Cherries.

Proceed with the budding of Roses as fast as possible, and if the weather is dry on light soils it will be necessary to give plenty of water and mulchings to assist the buds to take freely. Roses have made a very free second growth, which is just now furnishing a very fine supply of blooms, and from these shoots any amount of buds will be procurable. Roses in pots must be plentifully supplied with liquid manure to assist them to make firm and strong growths early, which is so necessary for next year's bloom.

Pinks, Picotees, and Carnations ought now to be layered if it is desired to increase the stock of these long-cherished and old-fashioned flowers. Begin by thinning-out any weakly growths, then remove just a few of the leaves near the base of those remaining, and with a thin-bladed knife split the stem about half an inch below a joint where the leaves were removed. Place some light soil around the plant or stool, and peg out each layer regularly with a wooden or metallic peg. Give a good watering from a rose watering can and the layers will soon emit roots, when they may be taken off and finally transplanted to their blooming stations. Pick off all flowers from Campanulas as they wither; these if kept constantly gathered without being left to swell their seed pods will throw out a second supply of flowers, which will add to the beauty of the herbaceous border later on in the season. Stake Dahlias, Hollyhocks, and Gladioli before there is any danger of their being blown about and broken off by the winds. Increase spring-flowering bedding plants. Pansies will increase most readily now by inserting cuttings thickly under a handlight, the blue and yellow selfs are most suitable for masses in beds or for lines on borders.

Sow the various kinds of *Silenes*, *Myosotis*, *Nemophila insignis*, *Saponaria calabrica*, and *Limnanthes Douglasii* and grandiflora in an open piece of ground, and water frequently if dry weather continues. If sown at once they will make strong plants for lifting and transferring to the flower beds on removal of the summer occupants. Daisies and Polyanthus that were laid in temporarily in the reserve garden at the time when the summer bedding plants were planted should be increased by division and receive bountiful supplies of water. These are amongst the earliest of spring-blooming plants, and ought to be used more extensively than they are.

The beauty of the flower garden has been greatly enhanced by the recent warm weather. Geraniums, &c., are now blooming well, and the plants used in carpet bedding have not only grown well but the colours are fairly good. Most of these high-coloured-foliage plants improve by frequent waterings overhead, and where the soil is of a dry and gravelly nature we give it a slight covering of cocoa-nut fibre, which not only removes the unsightliness of the soil, but brightens and better defines the separate colours. Coleus, Pyrethrums, and many other such-like foliage plants require pinching and clipping to keep all the colours at a uniform height and distance, and have the edges of the beds frequently clipped. Attend often and regularly to all these little requirements, for the summer months are fast fading away, and before long the flower garden will be again shorn of its beauty.

Under glass there is a breathing time. Vines are finishing the swelling of their crops, and Peaches and Nectarines are fast approaching to maturity. The conservatory is gay with many stove plants, and the hardwooded greenhouse plants which have done flowering will be benefited by being placed out of doors on a partially shaded border, the night dews and refreshing rains being highly beneficial to their growth. It is the only season of the year when greenhouses may be made empty with ease, and this affords an excellent opportunity for cleaning the plants, for repairs, painting, and other requisites. Pelargoniums that have been placed out of doors to ripen should be cut-in, the tops being made into cuttings and inserted for an increased next year's supply, the plants, after having made a little fresh growth, being shaken out and repotted into smaller pots.

Cucumbers and Melons in frames require regulating and frequently watering overhead before closing on warm days. Cucumbers if planted now on a fresh bed of manure will furnish a late supply of fruits.

Sow herbaceous Calceolarias at once, and shift-on Cinerarias and Primulas as their pots become filled with roots. Calceolarias and Cinerarias thrive best in a cool temperature. A frame turned to the north instead of facing the south is a suitable place for them. Keep the plants somewhat shaded and close during the day, but the lights may be drawn fully off at night, and the plants will be benefited by the heavy dews. Pot Cyclamens, and shade them from bright sunshine until new growths are made. Sow Intermediate Stocks for flowering in pots and planting-out next spring. Geraniums that have recently been potted for winter blooming should have liberal treatment, and all blooms picked off until the end of September; other plants may be cut back at once, when they will break and be useful later on. Chrysanthemums should

be tied to supports, and as the growths are made they should be secured, or they are apt to snap at the joints. Specimen plants require to be tied out with small sticks, but plants grown for their quality of bloom are best secured by an improvised trellis, which prevents the wind from blowing the pots down.

WORK FOR THE WEEK.

KITCHEN GARDEN.

THE recent hot weather has done much to forward many crops that from the cold state of the soil were backward, such as dwarf and runner Beans, Vegetable Marrows, ridge Cucumbers, and Tomatoes; but Peas, Cauliflowers, &c., have been distressed by the drought where no waterings and mulchings have been resorted to. In hot weather vegetable crops can hardly have too much moisture at the roots. Celery especially should have an abundant supply of water and liquid manure, a good watering being afforded all crops that are liable to suffer from drought once or twice a week; mulching afterwards with short manure cannot fail being beneficial. Peas and all pod-bearing esculents ought to have the pods gathered so soon as they become fit for use, as allowing them to remain upon the plants speedily checks the growth, preventing successional gatherings being had from the same plants. Ground should be at once made ready for the main crop of autumn-sown Onions, winter Spinach, Cabbage, and Lettuce. We prefer to sow them from the 8th to the 12th of this month, having the ground prepared previously by giving a good coating of thoroughly decayed manure and digging it deeply in. Continue planting out late Broccoli, Savoy and Winter Greens of all kinds as ground becomes vacant. Lettuces soon run to seed in hot weather; keep them cool, therefore, by watering and mulching with short manure and watering the whole surface of the ground occasionally.

FRUIT HOUSES.

Pines.—Houses as they become vacant should be thoroughly cleansed before being again occupied with plants. The first thing to be seen to is the bed. If bottom heat be afforded by hot-water pipes, the material forming the bed, whether of tan or leaves, should be removed at least once a year, or insects, particularly woodlice, rapidly increase: the old material also harbours other predatory vermin. All brickwork should be brushed over with hot lime, the wood and ironwork thoroughly cleansed with soap and brush, keeping the soapy water as much as possible from the glass, which ought to be cleansed with water only. If needed the wood and ironwork should be painted. Beds that are chambered—i.e., the hot-water pipes covered with slates or other material, are very much in advance of those surrounded or passing through beds of rubble. Those composed of the latter should be turned over, and any dirt or small parts removed to allow the heat given off by the pipes to penetrate through the whole and diffuse uniform temperature to the bed. New material will be required for the bed. Fresh tan should be provided, of which 3 feet in depth is ample where pipes are placed beneath. If it be wet turn it over occasionally on fine sunny days. Suckers that were started in June will soon have filled the pots with roots, and should be shifted into larger pots before the roots become very closely matted together. Queens should have 9 and 10-inch pots, and those of stronger growth 11-inch pots. Water immediately after potting, and plunge in a bed having a temperature of 90° to 95°. There is no greater mistake in growing Pines than crowding young plants. The plants become drawn and weakly instead of having a sturdy base, a condition that should always be aimed at. Attend to the bottom heat of beds that have been recently upset by the removal and replacing of plants, not allowing the heat to exceed 95° at the base of the pots without immediately raising them, as too much bottom heat will disastrously affect plants with fruit or those having the pots filled with roots. Look over the plants for watering about twice a week, and maintain a moist, genial, well-ventilated atmosphere. The climatic influences are now so favourable that Pine plants grow luxuriantly; therefore discontinue any shading such as may have been employed for an hour or two at midday when the sun was powerful through the months of May, June, and July; the plants after this having the benefit of every ray of light, admitting air plentifully when the temperature ranges from 85° to 95°, affording to fruiting plants a night temperature of 75° to 70°, and successions 70° to 65° at night. Reserve, if possible, another batch of suckers on the stools for starting at the commencement of September.

Melons.—The weather has been of late all that could be desired for Melons, especially late crops in frames, which have set and are setting remarkably well, it being a notable feature that late Melons on dung beds grow very luxuriantly, and unless the foliage be kept thin the fruit sets very indifferently, and after setting refuses to swell. Some growers object to the use of the knife about the plants whilst the fruit is setting, but we hesitate not to cut out superfluous growths whenever the necessity for it arises, and with the best results. A crowding of the foliage tends to nothing but disaster. The blossoms do not set well, the fruit swells badly, and, worse still, they have large seed cavities, are hollow, and have neither weight nor quality. Copious supplies of water are neces-

sary to plants swelling the fruit about twice a week, with a sprinkling overhead at closing time, those in houses being well syringed both ways in the afternoon, and a good moisture maintained by sprinkling the floors, &c., two or three times a day. Do not neglect to impregnate the flowers daily of plants now in bloom, and to go over the plants frequently for the stopping or removal of superfluous growths. Keep the atmosphere dry when the fruit is ripening and setting, maintaining a bottom heat of 80° to 85°, top heat 70° at night, 75° by day, in dull weather admitting a little air at that if the day be likely to be fine, allowing the heat to rise to 80°, then admit more air, increasing the ventilation with the increased temperature up to 85° or 90°, closing at 80°. A free circulation of rather dry warm air greatly improves the finish and quality of Melons when near upon ripening.

Cucumbers.—Any frames that are at liberty may yet be planted with Cucumbers upon a bed of fermenting materials, which will give a supply of fruit in September, and continue up to near Christmas if due regard be had to lining the bed and to protecting the plants by mats over the lights at night in cold weather. Let plants in frames or houses be cut over at least once a week, removing exhausted growths to make room for young bearing shoots. Keep the shoots well stopped to one joint beyond the fruit, or at the fruit if the plants are vigorous and showing no signs of exhaustion. Maintain a steady root-action by the necessary bottom heat and due attention to watering two or three times a week, affording the temperature top and bottom as given for Melons. Syringe both ways in the afternoons of bright days and close early, but avoid late syringing, for the foliage should be nearly dry by sunset, and commence ventilating early, it being important that the foliage be not powerfully acted on by the sun without ventilation accompanying, or the leaves will in all probability be scorched. The autumn fruiterers should now soon be planted on ridges or raised hillocks moderately firm, maintaining a moist and genial atmosphere, and they will grow away freely and show fruit in plenty shortly.

FLOWER GARDEN.

This is now expected to be at its best. Every possible attention should be given to have all the surroundings in the best order; nothing tends so much to disfigure a place as weedy beds, borders, and walks. Weeds should be combated in the small or seedling state. Ragged edgings are equally objectionable, and should be frequently gone over with the shears, and the whole surface of beds and borders where available should be given a neat appearance. It is hardly necessary to point out the necessity of keeping walks well rolled, and the lawn smooth by cutting with the machine as frequently as occasion may arise, but avoid cutting very close in bright weather, as it will have a tendency to brown the grass. Let the machine be set high in hot dry weather so that any uneven growths of grass only may be cut. Border plants should be attended to in staking and tying as they advance in growth, removing at the same time dead flowers and seed pods from such plants as are going out of bloom, for want of which attention herbaceous borders often have a neglected appearance.

Pipings of Pinks may still be inserted, and any that are rooted should be potted off in pairs in 3-inch pots placed on ashes in a cold frame. Until the potting is recovered from shade the plants from bright sun, and then admit air fully. If hardened off when well rooted they may be planted out where they are intended to bloom. Carnations and Picotees if not yet layered should be proceeded with, and seed may be sown in pans placed in a cold frame. The summer bloom of Roses is now nearly over; all straggling shoots should be cut back without delay, all faded blooms and seed pods be promptly removed, and every encouragement be given the plants by watering them overhead in dry weather and copiously at the roots, mulching the soil afterwards. Suckers from the roots and robbers upon the stems of standards must be removed as they appear. Continue inserting buds. Those inserted early will soon be sufficiently forward to have the ties loosened or entirely removed. Dahlias, Hollyhocks, and other gross-feeding plants will require abundant supplies of water in dry weather and manure water, but mulching is preferable, as it insures surface-rooting. Tritomas, Pampas Grass, &c., are liable to suffer from drought, and should be assisted with copious waterings. Nothing answers so well as mulching the surface of the beds and borders in which plants are grown that require abundant supplies of water, as all flowering plants do in a period of drought, the mulching saving watering, insures more regular moisture, attracts the roots to the surface, where they feed directly upon the matter supplied to them. More particularly is this the case with dwarf Dahlias, Asters, Stocks, Zinnias, and other descriptions of plants free in growth and affording large flowers in quantity.

The subtropical plants should be attended to in staking and tying betimes, and be abundantly supplied with water, particularly gross feeders, such as Cannas, Castor-oil plants, and Wigandias. Carpet beds should be regularly trimmed, for which they well repay, being always bright; the heaviest rain does not take the colour out of them, and hot dry weather only heightens their beauty. The finest beds we have seen this year were carpet beds, which were kept in fine order by pinching and stopping twice a week.

Clematis and Tropæolums will now, if they have been well attended to, be in great beauty, and should have attention in respect of training for some time longer, which is essential to their pleasing appearance in dressed grounds; but where they are planted to cover old stumps and trunks of trees, or spreading on and overhang rock or nooks and corners where they can be accommodated with a few sticks to afford support, anything like trimness should be avoided, only slight training may be resorted to for the better securing of the object sought.

The propagation of bedding plants for another season must now or soon have attention. Pelargoniums that are cultivated for the beauty of their leaves should be propagated forthwith, inserting three or four cuttings in a 3-inch pot placed on ashes in a cold frame, but with the lights off, yet in readiness to afford protection from heavy rains. This applies more particularly to the choice moderate-growing varieties, but any free growers as well as the green-leaved varieties strike freely inserted in poor soil in the full sun, taking them up and potting when well rooted. If stock plants of such as *Alternantheras*, *Coleus*, *Iresine*, &c., were not reserved for propagating from cuttings should be struck at once, so as to have strong well-established plants by autumn, without which they cannot be expected to winter satisfactorily. Those fortunate enough to have a reserve garden will find the benefit of it now, as it is, to say the least, annoying to be cutting the plants in the flower garden directly they begin to fill the beds; and unless carefully done unsightly gaps are made and a quantity of bloom removed, which is undesirable, and with a reserve garden unnecessary.

PLANT HOUSES.

Stove.—*Toxicophlæa Thunbergii* and *T. spectabile* are very desirable plants, not unlike a *Gardenia* in growth, the flowers borne in corymbs like an *Ixora* but much smaller, white, and deliciously fragrant, a few flowers scenting a large house. They do well in sandy peat, and must not be overpotted. They flower freely in a small state. Young plants of *Gardenias* that were struck about this time last year or early this spring will need a shift into 8 or 9-inch pots, according to their strength, which should be given at once, as nothing injures young plants so much as allowing them to become root-bound. If a batch of plants well set with buds and which have been rested for a short time be placed in bottom heat and afforded a brisk moist top heat they will come in useful when flowers are becoming scarce.

Gloxinias as they go out of bloom should have water gradually withheld, and when the tops go off place the pots on a moist bottom, where there is a temperature of about 45°, in which they winter safely. Late-flowering plants should have a position near the glass shaded from bright sun and be well supplied with water, liquid manure being given after the flowers show. *Achimenes* should not be dried off too quickly, as is too often the case, but must have water to prevent severe flagging. Plants in flower are the better of shade from bright sun, but anything like gloom is not promotive of sturdy growth and free flowering; therefore keep plants for late bloom near the glass with no more shade than to prevent scorching, affording them weak liquid manure, and staking and tying as required. *Tydas* should have every encouragement to make a good growth, with similar treatment to *Achimenes* as to light, watering, &c. *Gesnera exoniensis*, *G. zebрина*, and *G. zebрина splendens* coming on for winter bloom must have a position near the glass to keep the growths sturdy and the leaves in good colour, affording them water copiously, but avoid overdoing it, which is as bad or worse than overdryness. *Gesnera Cooperi* and *G. Donkelaari*, and others of that section coming on for second bloom should be encouraged with weak liquid manure, and kept in a light position.

Francisæas that have completed their growth should be removed to a cooler and drier house to firm the wood. Any early-flowered plants that have made a good growth and been exposed to light may be kept cool and airy for a few weeks, then if placed in brisk moist heat they will come into flower in late September and October, and be very acceptable.

Allamandas and *Dipladenas* that have been for some time in bloom will have the flowering prolonged by copious supplies of liquid manure about every other time they require watering. These and other climbers of free growth planted out should have free waterings with liquid manure. *Æschynanthus* plants in suspended baskets or suspended pots must not lack for water, but an excess is equally pernicious, both extremes causing them to cast the flowers. Few plants equal them in late summer and autumn, it being remarkable that they are not more frequently seen.

All winter-flowering plants, such as *Plumbago rosea*, *P. coccinea superba*, *Poinsettia pulcherrima*, *Sericographis Ghiesbreghtiana*, *Æranthemum pulchellum*, *Aphelandras cristata*, *aurantiaca*, *aurantiaca Roelzii*; *Euphorbia jacquiniæflora*, *Centropogon Lucyanus*, *Thysacanthus rutilans*, &c., should be encouraged to make strong growth by keeping them near the glass, or where they will receive plenty of light in a growing temperature, syringing them every evening to keep thrips and red spider under. The last pinching should now be given to *Euphorbia jacquiniæflora*, as, if deferred until late, the growths will be weak and will not flower satisfactorily.

Stove plants during hot weather require abundant atmospheric moisture, syringing morning and afternoon, the latter at about 5 P.M. or earlier, being regulated by the time of closing, as it is desirable to have the foliage mainly dry before nightfall. Admit a little air at 75°, increase it with the temperature after 80° is reached, running up to 85° or 90°, and close at 80°, and if it rise to 85° or 90° from sun the plants will enjoy it.

TRADE CATALOGUE RECEIVED.

Henry Boller, 73, South Row, Kensal New Town, London, W.—*Catalogue of Succulent Plants.*

TO CORRESPONDENTS.

* * All correspondence should be directed either to "The Editors," or to "The Publisher." Letters addressed to Mr. Johnson or Dr. Hogg often remain unopened unavoidably. We request that no one will write privately to any of our correspondents, as doing so subjects them to unjustifiable trouble and expense.

WINDOW GREENHOUSE (S. S.).—We cannot recommend any tradesmen. Refer to our advertising columns.

WILLOW FENCING (G. Stenson).—It would not injure cattle that ate its leaves.

ADDRESS (A Lover of Rose Shows).—Write to Mr. Duffield, ironmonger, Slough, who can, Mr. Turner informs us, supply you with what you require.

DISEASED LEAVES (C. V.).—They are all mildewed. The only remedy is the repeated application of flowers of sulphur.

SWEET WILLIAMS AND ANTIRRHINUMS (W. C.).—The flowers of the *Dianthus* are diversified in colour and represent a good strain. The *Antirrhinum* are varied, and similar to those you have previously sent to us, and of which we have spoken approvingly.

VARIOUS (Cricket).—Sprinkle Scotch snuff over the haunts of the crickets. Add some sandy soil to the clayey herbaceous border, and the same sandy soil would suit the *Lilies* in the low ground. We cannot name a plant from leaves only.

STOVE, GREENHOUSE, AND HERBACEOUS PLANTS (W. M.).—Consult the nearest florist, who will know your houses, &c.

MIGNONETTE CULTURE (Cambusmore Mound).—Enrich your light sandy loam with a heavy dressing of manure, water thoroughly in dry weather, and you will have no further trouble. The browning of the foliage and premature decay of your *Mignonette* is caused by poverty of soil, and probably also by drought. *Mignonette* loves a generous diet and well repays us for it.

GROWING GRAPES WITHOUT ARTIFICIAL HEAT (W. M. G.).—"LINCOLNSHIRE GARDENER" is quite right and you may safely follow his advice. The note by "PRACTICALIST" should be regarded by you as a scientific hint to growers of delicate Grapes in what are termed late vineries. So regarded it is really valuable and does not clash with that of our other correspondent. Only take care to plant hardy sorts of proved excellence, to afford a free and abundant circulation of air among foliage and fruit, and you will have very little loss from scalding.

CUCUMBERS PRESERVING (J. R. S.).—We do not remember the notes on preserving them in the earth.

ROSES (J. S. M.).—We know of no book such as you name. Our "Garden Manual" contains full directions.

GERANIUM LELEGANTE NOT FLOWERING (A Constant Subscriber).—The paucity of flowers is attributable to one of two causes—smallness of the plants, or richness of the soil, or to both in combination. In very rich soil growth is always made at the expense of blossom. Take the cuttings for next season's stock as soon as possible, give the young plants rich soil while in pots to induce a free growth during winter and spring, but let the soil of the flower bed in which you plant them next summer be poor, and you will no doubt have plenty of flowers.

CYCLAMENS AFTER FLOWERING (Idem).—They require a partial rest, but not by any means a drying-off, a cool shaded place outdoors being suitable for them. When signs of growth appear the plants should be repotted, removing carefully a good portion of the old soil, and potting in pots the same size as before or slightly larger, using light turfy compost; afterwards place in cool frames, or the plants may be planted out in rich light soil and potted in September. They do not usually improve after they have flowered for four or five years, and it is advisable to raise a few plants from seed every second year to insure a stock of vigorous plants.

THRIPS ON CARNATIONS (D. G.).—We cannot suggest any better means of driving the insects from the flowers than syringing them copiously and frequently with pure water. The application of an insecticide would either injure the blooms or spoil their perfume. Thrips are seldom prevalent in showery weather, hence we advise syringings to be applied early in the morning and again towards evening.

AUCHUSA ITALICA (Idem).—This hardy border perennial is readily increased from seed, which should be sown at once in the open border, the seedlings being transplanted 6 inches apart as soon as they are large enough to be handled, and subsequently planted in their blooming positions. The plants may also be increased by root-division in the autumn. Incorporate leaf soil, lime rubbish, or any gritty matter, also soot, with the strong soil of your border, and you will succeed in growing herbaceous plants well.

LIQUID MANURE FOR VINES (J. W. L.).—As your Vines were planted this year in a new border 14 feet wide, we do not think they require any liquid manure. Assuming that the border is good and the Vines in a fair degree healthy, the one bunch on each Vine will not be exhaustive. We do not approve of inducing a succulent growth by the application of stimulants when the Vines are young, but prefer moderately strong, short-jointed, hard canes with prominent buds. As your Vine border is inside soak it thoroughly with pure water. If you are anxious to try a stimulant, mix half an ounce of guano in each gallon of water and apply immediately after

it is mixed, but unless your Vines are weak we do not advise any such application this year.

INSECTS ON MELONS (*A Subscriber*).—The leaves sent contain evident traces of red spider and slight traces of thrips. As the plants are trained to a trellis overhead you need have no difficulty in cleansing the leaves and securing a crop of fruit. Syringe the plants thoroughly twice a day, except a period of dull weather occur, when once a day will be sufficient. Apply the water directly to the under sides of every leaf with some force, taking care, however, not to injure the foliage. Do this until several flowers commence expanding, then keep the plants drier until the fruits have set, then syringe as before until they approach the ripening stage. Keep the roots healthy and well fed. Pinch the laterals as they grow, not letting the growths become tangled and crowded, and then having much to cut out at one time. Ventilate early and close early. Do not let the minimum night temperature fall below 65°, and in due time you will have good fruit.

NAMES OF PLANTS (*J. M.*).—No one can name a plant from the fragment of a leaf, and the frond has no spores. (*L. H.*)—It is an Aloe, but we are unable to name the species from the scrap of leaf sent. (*Tyro*).—1, *Centaurea Scabiosa*; 2, *Potentilla formosa*; 3, *Aconitum versicolor*; 4, *Bad* specimen; 5, *Epilobium angustifolium*; 6, *Polystichum Lonchitis*.

THE HOME FARM:

POULTRY, PIGEON, AND BEE CHRONICLE.

HARVESTING OF WHEAT.

It is a matter of great consequence to commence the cutting of wheat at the right time, so as to insure the greatest value of both grain and straw, the latter being now much more valuable than at any former period, and is in fact sometimes of as much value per acre as the grain in those seasons when the yield is deficient. It must, however, be borne in mind that, generally speaking, the best time of cutting to secure grain of first-rate quality is also the most likely to save the straw of the most value. The period of growth or ripeness for cutting wheat is usually indicated by the colour of the straw; but the surest way is to examine the corn, and if upon pressure there is no milk-like moisture in it, then the grain will be fit for cutting, and the longer it is delayed when once ripe the more injury it receives. Although the sun has great power for good in the ripening of the grain, yet it has also power for evil by damaging the sample and gradually changing the colour, thickening the bran and reducing the weight and quality of the flour. Besides this, when wheat is cut early and set up into shocks it is safer from damage by rain than when standing, because when in sheaf a small portion only would sprout in a wet harvest, whereas if left standing the corn may sprout as it stands or be whipped out by the wind.

In cutting wheat the straw should always be dry, for if cut and tied when wet it will never properly become dry again without opening the sheaves, which is a matter attended with serious waste and loss. Nor should the corn ever be allowed to remain upon the land in grip and untied, as in case of rain both straw and grain will receive more or less injury. The method of cutting wheat upon the home farm must depend to a certain extent upon the size of the farm and whether machinery is available or not. If it is available there is no means of cutting and securing the grain with so little loss and delay as by the use of the reaping machine, the best being that made by McCormick & Co., whose agents are Waite, Burnell, & Co., 228, Upper Thames Street, London, E.C., with self-binder attached. The binding is done by wire, and has now been proved to be effective. There is, however, some objection to the use of wire; but some trials have taken place, using twine or other materials for binding the sheaves, which is not yet held to be done with advantage as compared with wire.

Now on many of the small farms the purchase of such expensive machinery cannot always be considered a prudent investment. In such cases we must fall back upon hand labour unless we have the opportunity of hiring the reaper and mower, in which case the hire will be money well spent, not only by reason of the best work being made, but also by the celerity with which the harvest operations can be carried out and fine weather being made the most of. We can recollect various seasons during the past fifty years when upon some farms nearly all the wheat was cut and stacked without rain, but upon adjoining farms we have noticed that no wheat had been secured, a succession of wet weather having caused serious loss, and showing the propriety

of cutting and carting the corn when it is ready without reference to other comparatively unimportant farm work. In cases where machinery is not available upon the home farm the manager must of necessity continue to conduct the harvest work by hand labour. It then becomes a question as to the best mode of cutting the wheat, whether by reaping, fagging, or mowing. The cost of reaping is more than by the other methods, and it is only to be recommended where there is clover or abundance of grass and weeds amongst the corn. In this case it is desirable to cut the straw high enough to leave the weeds behind and the clover untouched, so that it may be cut for green fodder further on in the autumn. Fagging when well done by men who are accustomed to the work is a cleaner and better way of cutting than mowing, because it can be done where the corn is laid or lodged, whereas the scythe can only be used with effect where the wheat stands upright. There is not much difference between the sheaves when fagged or mowed. In both methods the sheaves are hollow and loose, so that in case they take rain it soon dries out again; but when wheat is reaped and the sheaves are tied tight, especially when the sheaves are large, if they once get wet inside it is difficult to get them dry without untying, and this applies to both hand labour and machine-tied corn. Sheaves ought, therefore, never to be more than 12 or 14 inches through at the bond. After the corn is cut and tied the sheaves should be set up in shocks, about ten sheaves in each; and when they are set out at bottom and settled into each other at top the rain is excluded nicely, and the shocks are not likely to be thrown down by wind. It is, however, a good plan in exposed situations to make the shocks round, with about the same number of sheaves in each. When the corn is much laid it cannot be cut with the scythe without loss, and fagging will then be found the only way to cut the corn most advantageously.

Carting the corn to stack so as to prevent heating is one of the most important operations during the harvest, for the grain of wheat heated is useless and unsaleable for general purposes. Nothing but experience will teach the farmer the right time to take the corn to stack, for in case weeds are found amongst the corn to any great extent it will require probably a week or ten days in the field; but when the wheat is fully ripe and without weeds, if the weather is dry and hot and the sheaves have not taken rain, they may be carted to rick about three or four days after cutting. And often when dead ripe the corn may be carted to stack as fast as it is cut and tied; for it must be remembered that the best samples of grain are those which are obtained from the earliest cut and earliest secured, when once it is ready and not likely to heat in the rick or mow. No farm should be without the elevator and horse gear for rick-making.

In stacking wheat it is of consequence as to the size and shape of the ricks. It may also be stacked in a difficult time much sooner than it can be mowed in a barn, particularly if the ricks are not made too large. We like them best to consist of from twenty to twenty-five waggonloads of sheaves. It is a common method in some districts to make the ricks oblong, but we like the round stacks best, as there is not so much outside, and the thatch is not disturbed so much by the wind. It is the most convenient plan to put two ricks near enough together for the thrashing machine to dispose of both without moving the machine. The straw, too, may then be made up into a single rick and thatched for sale or preserved for use. Moderate-sized ricks are not so likely to heat, and are more easily thrashed of a short day in the winter or when the weather turns out adversely. Ricks, however, intended to be held over until the following summer should not be made upon the ground, but are best placed upon a stand in order to preserve the grain from the depredations of rats and mice, iron stands being the best.

WORK ON THE HOME FARM.

Horse Labour now consists of working the fallows, some of which will be in preparation for wheat or winter oats. As soon as the peas or winter beans are harvested the land may be rafter-ploughed—that is, half ploughed—and then scarified crossways twice. It may then be harrowed, rolled, &c., and by this means

the grass and weeds will be kept on the surface instead of being buried under the soil by whole ploughing. This plan will enable the land to be worked with the chain harrow, and the best implement we have seen for this and all other purposes where the chain harrow is required is the latest invention of Howard's flexible chain harrow. This implement we greatly approve for general purposes; by its use the grass and weeds are drawn together, and may then with the least amount of hand or horse labour be carted away to heap or otherwise disposed of. Horse-hoeing will still be required for the latest Swedes and turnips, and we have often found it a good plan to entirely cut up the weeds between the rows of turnips. Instead of going once with the horse hoe between the lines we do the work at twice, holding hard up to the line on one side, and so continue throughout the field. After two or three days we go over the field again and hold the hoe hard up on the other side, and should any of the plants be partially buried with the loose earth they will have had time to release themselves and become erect between the first and second operation. By hoeing hard up to the lines in each hoeing the weeds will have been more completely rooted up than they would by the horse hoe only passing once between the lines. The horses will also be employed in reaping such corn as may be ripe, either rye, winter oats, white Canadian oats, &c., the latter being a very early sort. We saw a sample of this variety sold in a southern county corn market on 19th of July last, the grain weighing 46 lbs. per bushel. In this case the land being cleared of the crop so early there is a capital opportunity to obtain a good crop of stubble turnips, perhaps even better than if sown after an expensive fallow preparation. The odd horse will be engaged in collecting hedge trimmings for burning, also carting clover for horses, cattle, and pigs. It is important that the succession of green food should be insured as much as possible by looking forward and taking care that if possible a third cutting of clover may be obtained; or green fodder may be available where vetches and oats have been sown in admixture. We have seen lately some very promising crops of this kind sown after trifolium cut up for cattle, and in other cases after vetches and oats cut up. The advantage of this late cropping for green fodder is great. If this has not been provided it may be well to reserve a piece of second-cut meadow grass, and we have some now which bids fair to be capital food for horses, &c., as late as the months of September and October. We have often grown capital crops of clover when seeded in the wheat, and the corn cut high enough to reserve the clover untouched; it will then on the average of seasons produce a valuable crop of green fodder until the early frosts of November begin. In this plan of feeding the horses do much better than by feeding on hay, and the longer the hay feeding for horses can be deferred the better. It has sometimes been imagined that cutting the young clover in the autumn would injure the produce in the following summer, but we have never found it so; in fact it is much better than close feeding by sheep, which is a common practice. As soon as the second cutting of clover is carted, the land being intended for wheat, the sooner the yard dung is carted out and spread thereon the better. The ploughing and pressing should follow immediately, as early ploughed lea ground is sure to give the best preparation for wheat, more especially upon the loamy and mixed soils.

Hand Labour.—The men not engaged in harvest work will be now employed in hand-hoeing the turnips, and care should be taken not only to leave them singly, but leave the strongest plants, for these will always bring the best bulbs. When down ewes are kept for producing early lambs this is the time to turn out the rams. The best kind of down ewes for this purpose is not the Hampshire downs but the Dorsetshire downs, as they will generally offer to the ram earlier than the Hampshire downs. As many of the Dorset flocks are descended by crossing from the horned sheep they will in consequence breed sooner in the year, and bring a greater number of lambs; the shepherds will therefore be now required to give the ewes a constant change of fresh grass, saintfoin, vetches, &c.

THE TRIAL OF INCUBATORS.

THE forthcoming trial of incubators at Hemel Hempstead cannot fail to be of the highest interest to all who keep poultry whether for pleasure or profit. English springs do not improve, and year by year we hear increasing complaints among amateurs of exhibition poultry that they cannot procure sitting hens in the early months, and that consequently their chances of success at the chicken shows are much lessened. On the other hand, those who regard poultry from a commercial point of view would find their profits immensely increased if any reliable incubator were introduced, which would not only obviate the trouble of a multitude of sitting hens and coops, but would also insure the hatching of abundance of chickens at the time desired. As far as we know this will be the first occasion on which any competition of the kind will have ever taken place on satisfactory and equitable conditions. A prize was last year offered for the best incubator at the Agricultural Hall Show, but the award was, we believe, made solely with reference to the apparent ingenuity of the instrument and the consequent probability of its success. It need hardly be

pointed out that this is a most unsatisfactory and delusive test. Nothing would be easier than to put in eggs incubated in the natural manner about to hatch at the time of trial; the apparent success would be sure to influence most judges, however anxious to make fair awards. Could a certain amount of mechanical ingenuity insure success in artificial hatching assuredly it would be commoner than it is.

Interesting to us as the subject is, we are almost tired of the various descriptions of incubators, each with some carefully elaborated method for the imitation of Nature, especially as to the moisture to which eggs are nearly always subjected. Unfortunately in practice many of these instruments are not found to correspond to the anticipations of them formed in theory. We do not for a moment wish to depreciate the scientific care with which such inventions have been worked out, but it does seem a little provoking that the accumulated knowledge of this nineteenth century of grace cannot accomplish what was performed thousands of years ago by those whom we are wont to consider mere empirics. Some weeks ago we sketched the earlier history of artificial incubation, and were on the point of proceeding to discuss incubators of the present day, hoping from statistics sent us to compare the various instruments now in use. Many fanciers kindly sent us their experience, but the results were so extraordinarily different that we could really base little upon them, and every month seemed to bring to our notice some fresh invention or adaptation of one; so we decided to postpone the subject for a time, believing it fairer to wait till we could draw conclusions from wider experiments, or till we could ourselves watch and, if possible, compare some of the most famous instruments. This preliminary work will to a considerable extent be done for us at Hemel Hempstead next September. The scheme is certainly a most praiseworthy and spirited one, and the promoters of it deserve our hearty thanks. The contest begins at 6 A.M. on September 5th and ends at noon on September 26th, at which time the prize of £25 (a most liberal one) will be awarded to the incubator which has produced the largest per-centage of living chickens from fertile eggs.

All the conditions of the contest are worth studying. The incubators are to be delivered on August 31st, and will be worked by and solely under the charge of a special committee, one of whom is, we believe, an engineer, throughout the trial. We fear the four intervening days will be found hardly time enough to unpack the incubators, get them into working order, and master the principles of duly regulating each one, at least if those entered require anything like the preliminary care which some that have been under our own inspection do. This strikes us as the weak point of the regulations. Should, however, any difficulty arise on this score it might, perhaps, be obviated by postponing the contest a day or two. We heartily approve of the determination to test the machines independently of their inventors from written directions alone. If only time and care are taken to get over the preliminary difficulties of regulating the heat of each one severally, this method is obviously the fairest. It is a great point of merit in an incubator to be easily worked by a purchaser from printed directions. We were last winter staying with a friend who was trying one of a make of which we heard much boasting a year or two ago. The manufacturer asserted that under his care the identical instrument had worked capitally, yet in the hands of a most intelligent person with full written directions nothing like the desired temperature could be kept up. If incubators are to be of real use they must be suitable for general introduction, and they can only so be if their management is simple and comprehensible to ordinary unscientific mortals.

Lastly, "a report of the working and results of each incubator will be published after the competitions." We look forward to this as likely to be of great value, for we may thereby learn at what point some particular machine fails which may have been working well up to that point, and so it may turn out that one which is not absolutely successful in this contest may be capable of being advanced towards perfection. On the whole we hail the contest with much pleasure. We hear that it has been criticised in some quarters, but for our own part we never fail to rejoice at such schemes set on foot by those who can derive no profit from them, but, on the contrary, give much valuable time and attention for the good of their neighbours and fellow fanciers.—C.

OPEN TIME FOR BRITISH BIRDS.

AUGUST 1st being the end of the close time for British birds practical bird-catchers and the "bird frighteners," as non-professionals are called, will begin their operations. Soft-meat and seed-eating birds will be taken by the "pull net." A pull net varies from 6 to 14 yards in length, and covers from 12 to 20 feet in width; the bird-catcher works it with a string, standing about 20 yards away. The best time for seeing these nets in full operation is at daybreak on commons, waste lands, or seed-growers' grounds. After ten o'clock in the morning the catching ceases to a great extent, for the birds having fed "lay up." Towards the evening the birds again work the feeding places, but the bird-catchers generally have then left the ground. During ordinary

weather the birds are lured by decoy birds. Decoy birds used are of the same species as the birds sought to be caught. The furthest decoy bird will be placed in his cage 20 or 30 yards away from the net. The wild birds are attracted by the song of the decoy to within sight of the net; the wild bird is brought still nearer by other decoys until within sight of the "brace bird," which has been trained to his business. A piece of bobbin or other soft material is made into a figure of 8, and the bird is placed into it in such a manner that he is not hurt, but so that he has free use of his wings and legs. A swivel is attached to the underneath part of the brace, and a length of 4 or 5 inches then attaches the bird on to the "furr stick." The "furr stick" by an ingenious but simple contrivance, is made to rise and fall by the means of a string at the will of the catcher. When the wild birds are approaching the string is pulled, and the "brace bird" is raised up sitting on the top of the stick. Upon the lowering of the stick the brace bird "shows wing"—that is, he begins to flutter, as if settling on the ground. The wild birds imagine that the brace bird has found out a feeding ground, and they come to share in the spoil. The instant the birds have settled on the ground the bird-catcher pulls the pull-line sharply, and the nets are over in a moment. Even when the birds cannot make up their minds, and will not come within reach of the ground, the experienced catcher will strike them into the net when hovering within 3 feet of the ground. The takes vary from one bird to five or six dozen at one pull. The birds are carefully taken out of the net and immediately placed in cages, called "store cages." The doors of these cages are at the top, and made with the leg of a stocking fastened on; a usual wooden door would not answer, as the birds might slip out when fresh additions were made. All kinds of British birds, from a Wren up to a Rook, can be taken in the pull net. During ordinary weather the nets are worked by decoy and "furr birds" on the open lands; during the hot weather, such as at present prevails, the nets are worked on the margins of brooks, lakes, or ponds. Birds will go for miles to a clear running gravelly-bottomed stream. An experienced catcher on passing a suitable place can tell it immediately. The signs are that the shallow water at the edges of the pool is muddy, and the tracks of the birds visible in the mud. Birds frequent the water for drinking, washing, and moulting purposes about mid-day during the hot weather. By this mode of netting, which is called "the water trap," many rare British birds, which will take no notice of call birds, are captured. Amongst these rare and shy specimens are taken—viz., the Black and White Flycatcher, Woodpecker, Jays and Magpies, Doves, Wood Pigeons, Blackcaps, Butcher-bird, Lesser and Larger Pettichaps, Thrushes, Blackbirds, and all the Titmouse tribe.

There is another mode of catching birds—namely, by birdlime. The best lime is made from hollyback; there is also another good lime made of boiled linseed oil. Birdlime is mostly made by the catchers themselves; it requires considerable art to make it well. Good lime would hold a Duck or Parrot.

The birds principally caught by birdlime are Goldfinches, Bullfinches, Woodlarks, and Chaffinches. The best time for catching Bullfinches is in the blackberry time—viz., September and October. Birdliming is a more sporting mode of catching birds than netting. The Bullfinch-catcher finds his game principally by his own call. He walks along suitable lanes and margins of woods continually calling with his mouth; this is called "whooping;" it is the challenge or call note of the Bullfinch, and sounds much like "whoop," "whoop," "whoop." In some parts of the country Bullfinches are called "whoops." After a time the man finds his game by a bird answering his call. He immediately puts down a call Bullfinch in a cage, and a twig already limed near the cage. After a time the decoy "gets hold" of the wild bird by his call; the man then ceases, leaving the bird to finish the work.

The wild bird being of a pugnacious disposition he challenges the caged bird, and alighting on the stick he is done for immediately, being held fast by the lime. It is not an uncommon thing for a single-handed man to take two dozen Bullfinches in a day; fresh caught "Bulleys" realise to the catcher 12s. a dozen for cocks and 3s. a dozen for hens. Cock Bullfinches are in some parts of the country called "soldiers," on account of their crimson breasts. "Bulleys" are taught to pipe by being taken very young from the nest and one tune constantly hammered into their heads either by a bird-organ or by whistling. Numbers of birds, however, will not take to the song, in spite of great attention being paid to their education. The Germans are very clever in teaching Bullfinches to pipe. A trainer would think himself fortunate if four out of twelve "Bulleys" become pipers; the remaining eight will take a bit of the tune and not go on with it. These are sold as "broken pipers;" they are worth 3s. 6d. each. A perfect piper is worth from £3 to £4.

The Shrike Butcher-birds, or the small birds' enemy, are not plentiful this year; last year there were many. It is supposed that the fight this year did not hit this country, probably on account of the long, wet, cold spring. The food of the Shrike is grasshoppers, beetles, and small birds. In the autumn of the year they prey on the small insectivorous birds, such as the Chiffchaff, Willow Wren, and all kinds of small birds. It is not

an uncommon thing for the Butcher-bird to attack and instantly kill the bird-catcher's "brace-bird."

From the end of July to the end of August will be the most silent time of the year for birds. Birds are then all laying up for moulting for their new winter suits and for their autumnal flight. The first to go is the Nightingale. She chooses the first week in August to be off. The end of August entirely sends away the late Nightingales, to return again next April. The genial weather we have had lately suits this year's hatch of young birds. They have thriven well, and are very plentiful. The birdcatchers are preparing to reap their harvest previous to the autumnal flight. The summer birds will not all be cleared away from this country till the end of October.—(*Daily News*.)

VARIETIES.

WE remind our readers that the fourth metropolitan exhibition of the British Bee-keepers' Association will be held in the Royal Horticultural Society's Gardens, South Kensington, on August 6th, 7th, and 8th, when prizes of money and medals will be awarded for hives, produce, &c. Various manipulations by accomplished bee-masters will be made with live bees, which cannot fail being not only highly interesting but also instructive. The efforts of the Association to popularise apiculture in Great Britain merit much success, and the exhibitions are worthy of extensive patronage.

—AN American poultry-keeper has written that every chicken which had the gapes has been entirely cured by being made to inhale tobacco smoke. The treatment has done them no harm, and the trouble of smoking is but little if it is done when the chicks are in the coop. It takes but a moment to put them into a basket, and five minutes is as long as they should be subjected to the inhalation of the smoke, and not so long if it is strong enough to produce stupor. As soon as a chick is stupefied it should be taken from the basket and laid on the ground, when it will soon revive. Chickens that were nearly dead with the gapes when first treated got better with each treatment, and were cured after the seventh smoking.

—TURNIP FLY.—We are glad to know that this pest has not troubled the turnip crop this season so much as it has done of late. Mr J. Howden, Selkirk, writes a note introducing a method of preventing its ravages:—Take a quantity of sawdust well dried, say a bag, pour into it one gallon of paraffin oil and mix well; sow this upon the drills, either on the top or broadcast as may suit best. The sawdust, having absorbed the liquid, gives off the effluvia, gradually killing the insect without injury to the plant, two bags being sufficient for an acre. This can be easily tested in spots, and the expense is light.

—CHICAGO is able with improved machinery that has been tested within the last few weeks to desiccate from five to twenty thousand dozen eggs per day in such a manner as to keep them for any number of years in any climate. The amount desiccated could be doubled with little expense, and in this manner immense quantities will be canned when the market is low. The eggs are preserved simply by evaporating that portion which causes decomposition and decay, leaving the yolk and albumen, or the egg itself, in a rich golden-coloured granulation, which can be used in cooking at any time by adding water or milk according to directions to the desiccated egg, in which it readily dissolves in from three to five minutes. The difference between this and a fresh egg cannot be detected, as it is nothing else than fresh egg. By this method it is impossible to preserve limed eggs or eggs that are even slightly stale.

—A PARLIAMENTARY paper has been issued giving the importation of dead meat into the United Kingdom in the years 1876 and 1877. The following summary gives the quantity and value of the import for each month in the two years:—

	1876.		1877.	
	Quantity.	Value.	Quantity.	Value.
	Cwts.	£	Cwts.	£
January	81,992	216,626	136,396	373,344
February	114,920	283,639	154,969	405,518
March	110,928	278,890	188,213	492,369
April	95,708	231,682	140,409	362,716
May	69,656	172,543	190,350	459,926
June	76,037	182,929	125,655	308,851
July	56,919	130,362	95,624	246,189

—PROFESSOR E. W. STEWART writing on feeding animals states that the best feeders are fast changing their ideas of the proper management of young animals. It is not long since pig-feeders thought a slow early growth the best for the constitution,

and even the profit of the feeder. Pigs were kept over winter with little if any increase in weight. The feeders did not seem to discover that this food given to store animals was even worse than lost, for the animals took on an unthrifty habit, contracted their powers of digestion, and required in spring nearly a month of good feeding to recover from this penurious winter feeding. A thrifty animal with good management progresses without check from its first to its last day. When a little attention was given to the matter it became evident that the profit of growing meat was to be found in pushing the young animal as rapidly as possible, that it cost the least to produce a pound growth in the earliest period of life, and this cost in food grew proportionately greater as the animal increased in age and size. This, then, is the great fact underlying all successful feeding of young animals.

"MY BEES."

To and from Manchester cheap trips during Whit week are the order of the day. Many of the bee-loving community visit Manchester at that time, and some of them run out to Sale to see the old bee-keeper there. Some two years ago an old man from Nottingham came, who was then told that we considered him too old ever to become an active bee-keeper. Some time ago a letter came from this old gentleman, wherein he assured me that his bees had made life a new thing to him, and the world more interesting by half. We have had visits from many bee-men of Nottinghamshire, all much interested in the pursuit of apiculture. How beautifully strangers converse about their bees! To thousands of aparians the two simple words, "my bees" mean a great deal. What a perennial source of enjoyment "my bees" are! What hours of unmixed pleasure have I spent amongst them! What hours of real rest and recreation they have given to me, and hours, too, of uplifting reflection and admiration! There is an indescribable charm to thousands in the songs of the lark and the linnet; and in the floral world what chaste enjoyment is felt in the presence of the sweet, sweet rose and white lily! But pray who can tell the story of the pleasure derived from my humming and wonderful bees? There they are in my garden always humming by day and night. Where else shall we find a community equal to that of a bee hive, which presents so manifold and various features of interest? The community is a grand republic with a monarchical frontispiece. Its government is perfect, its laws never need amendment or alteration. Not a sound of discontent or murmur of disagreement is heard in that community. There is no fault-finding amongst "my bees," for there is nothing to find fault with. There is not one lazy or unskilled worker in the hive, no scamped-up work. Hours of labour are not counted, and rewards for labour are not needed. "My bees" come into the world qualified mechanics and architects with instincts for labour. Labour is their delight, and the hotter the weather the faster they fly and work! With what assiduity do they toil from morn till night, and from sunset till sunrise! What an amount of work is done by bees during the "night shifts" of summer! While other creatures are sleeping my bees are working in building combs, feeding their brood, and overhauling the honey which they gathered during the day.

I rise early to go into my garden to find that my bees are first on the move. They have been out early to get water for household purposes, and returning to the hives with a whizzing sound. They need a great deal of water, which is often gathered before the dew evaporates. And as soon as honey is in the flowers "my bees" will have it. Off they go with a cheerful hum to collect the sweets of the fields and forests which lie around them. They soon return with their honey bladders well filled and their pollen baskets heaped up. They come back laden like donkeys with panniers. Wonderful creatures! they are at their work all day long. After a chat and a cup of tea with my queen bee I visit my bees again in the garden. What a roar of prosperity and gladness do I hear around me! What numbers of bees do I see and hear at the doors of their homes, fanning and ventilating with all their might and main to make life and work possible and tolerable inside! What evidence is thus given of a community of interest! I weigh three hives, one has gained 5 lbs. during the day, another has gained 3 lbs., and the small hive has gained 1 lb. only. The differences of results are owing to the capacities and effective forces of the hives. All have done well, and I am satisfied with "my bees."

I look into my swarm hives and guess from the space filled that not less than 1200 cells have been built and completed in each of my strong swarms during twenty-four hours. Several of my stock hives have young queens just arrived at perfection, and are "piping" in downright earnest. Second swarms will come tomorrow or the day after if I do not cut out the royal cells with their royal inmates. I will let them swarm this year, as I intend to multiply my stocks. It is no small pleasure to a lover of Nature to see swarms gushing from their hives, taking wing joyous and jubilant, and making the air ring again with their cheers. In swarming they obey an instinct and impulse of their nature, and leave the comforts of home and the place of their birth never to return. They are somewhat like "Abraham, when

he was called to go out into a place which he should afterwards receive for an inheritance, obeyed; and he went out not knowing whither he went." How many interesting features are presented to the eye of thought by a swarm of bees!

In studying the history of bees it is impossible to individualise or to notice one bee as separate from the rest. The community must be studied as a whole. The queen bee is the only one that can be noticed separately, and she is a most interesting creature. She is reared in a royal cell and receives queen-like attentions before birth and afterwards. She with trumpet tongue proclaims from her cradle cell her right to the throne and her intention to occupy it at once. She thus heralds her birth and reign. She now comes forth a beautiful, stately, and queenly bee—queenly in her appearance and behaviour. The special attention she received in her cell-cradle made her what she is—very different in form of body from the working community, and perfect in her reproductive organs. She is queen of the hive and will become the mother of many succeeding generations. She is born amongst her own sisters and brothers, but soon these will all die and her own progeny will take their places and be her subjects and attendants. She will live four years, and her progeny will live but nine months at most. She will, therefore, outlive many generations of her own offspring. A fertilised queen lays about two thousand eggs per day in the height of the season, but often there is not room enough in the hive for all the eggs she produces. If we estimate a hive of bees at forty thousand in number, and calculate that three generations of these appear and pass away every year, we shall be able to make an approximate guess as to the fertility of a queen bee.

A queen bee is motherly and dutiful. What a life of toil and travail a queen bee leads, of constant journeying up and down the hive depositing eggs in empty cells. While queen of the hive she is servant of all, doing the hardest and most important work. In the production and deposition of eighty eggs per hour—two thousand per day—there is involved a great amount of toil, of wear and tear by night and by day. No truant hours are ever sought by a queen bee in the height of the season; no excursions for pleasure are ever allowed her, and no holidays for rest and recreation fall to her lot. No thoughtful man can follow the fortunes and career of a queen bee without interest, or fail to admire her conduct and character. She seeks no honour, but obtains it everywhere; she lives and labours among subjects that adore her. If some accident or the hand of death remove her from them at a time when no successor can be reared their habitation becomes one of mourning, and loud is their cry of lamentation. But in the absence of accidents and disasters queens die, and the approach of the times of their dotage and deaths may be at hand. The bees know this and wisely prepare for what is evident and inevitable. Royal cells are built and prepared, and young queens are reared in them to take the places of the old ones.

There is but little space left for remarks on the profits of bee-keeping, which heighten its pleasures. We all know that apiculturists have seasons of reaping and harvests of honey, when their good wives are pleased to see the shelves of their pantries and larders well loaded with supers and dishes of pure honeycomb. And we all know, too, that it is a pleasure to see heaps of honeycomb which has been gathered by our own bees, and it is a pleasure to eat them, or sell them, or give them away to friends and neighbours. Bee-keeping, then, is an enjoyable self-rewarding recreation. The remark of the old gentleman at Nottingham about his bees making life new and more interesting to him is not to be questioned.—A. PETTIGREW.

BAR-AND-FRAME HIVES.

I HAVE had during a visit to Dunoon the opportunity of seeing the bar-and-frame hives in use, Ligurian and hybrid bees working, and the slinger in full operation. The slinger is a valuable invention, and I saw it extract flower honey quickly and thoroughly.

Bar-and-frame hives are very interesting and instructive, but require a great amount of attention, and I feel sure that the large straw hives are more suitable, and far more profitable, for the working man. After a day of hard work the peasant does not care to be examining his frames of honey and brood and the many other little jobs necessary where frame hives are in use, and I think many will agree with me that frequently smoking his bees to see that combs are all straight and not fixed-in with propolis, extricating the honey from two or three frames, replacing them, putting in queen cells or ripe queens or fertile ones, Ligurian or black-ligurianising and such like, is only work for an enthusiast who has nothing else to do.

As to the Ligurian bees they are certainly brighter-looking insects, but from what I have seen I would not have them. The little wretches were so savage that I hardly dare approach them, one hive in particular; and whether hybrids or pure they were certainly not fit to be near where children are.

My friend informed me that his Italians went out in weather when the blacks dare not look outside. That may be so, but can

bees get anything in such weather, and are they not exposing themselves unnecessarily? This I do know, that my bees in 18-inch hives have done infinitely better than the Ligurians of my friend, and his locality is as good or better than mine.

At the end of the season I will send you an account of the weights of my hives, and if you think it worth while you may publish it for the benefit of the labouring classes and others who will be at a little trouble and less outlay to make a substantial addition to the yearly income.

The slinger I saw was Steele's of Dundee, and cost 29s. It would be useful in large apiaries to extract honey from black combs, but for my part I would give that to other bees to fill supers with pure honeycomb, the only form in which honey should be put on the table.—HARDY OF THE HILLS, *Northumberland*.

CONDEMNED BEES.

MR. J. GUEST, who is offered some bees by his neighbours, who always destroy them to get their honey, asks "if they are worth having, when they should be taken, and the best way of feeding them."

I wish this correspondent, and all the apian readers of this Journal, to know that I value bees in autumn so highly that two years ago I bought twenty swarms in September (5 lbs. each), at 1s. 6d. per pound—that is, 7s. 6d. per swarm, and the expense of carriage besides. If the calculation is correct that 1 lb. of bees contain five thousand in number, we see that the person who sent them saved five hundred thousand creatures from the brimstone pit, and got £7 10s. for his trouble. I am willing to buy twenty swarms at the same price this year.

We advise our correspondent to accept the bees offered to him, to have them in 4 or 5 lb. swarms in 16-inch hives, and give each 5 lbs. of bees (each swarm of that weight) from 20 to 25 lbs. of sugar made into good syrup. If the swarms offered be small let two or three of them be united in one hive with four or five cross sticks in it.

The best way of feeding such swarms is by using a flower-pot saucer half full of chips of wood and placed on the centres of their floor boards. The saucers should be large enough to hold one and a half quart of syrup each, and be refilled every night at sunset by means of small tubes or pipes of iron, lead, or wood driven through the sides of the hives and resting in the saucers. In this way swarms can be fed without disturbing the bees or even touching the hives and covers. There is no other mode of feeding swarms equal to this for simplicity, ease, and safety. An old rusty dripping tin or other vessel may be used instead of flower-pot saucers. I say rusty with a view to prevent new tin vessels or smooth pie dishes being used. If bees cannot crawl up the sides of smooth vessels they fall back into the syrup. But even pie dishes and new dripping tins may be safely used if they are filled with chips of wood, or hay, or straw, and when the 20 or 25 lbs. of sugar have been given the vessels and the tubes should be removed and the small tube holes corked up. How easy thus to create stocks of bees of superior value, for there are no stocks of bees better than those fed with sugar.—A. PETTIGREW.

OUR LETTER BOX.

EGG WITHIN AN EGG (*H. M.*).—It is not an unusual occurrence.

HIVES LOSING WEIGHT (*Mrs. D.*).—Your bees have done well considering the weather we have had this year. Each of your hives has given two swarms, and two of the swarms have been put together in a Stewarton hive. You fancy that as your supers and ekes have not been entered, and some of your hives are losing weight in fine weather amid good pasture, something must be wrong. Rest assured that your bees are not lazy or voluntarily idle, and that when honey is in flowers they gather as much of it as they can; but they cannot gather it when it is not to be found, neither can they fill supers and ekes and yield swarms at the same time. The two swarms put into the Stewarton hive had nothing to do for a time but build combs and store honey. Your old hives were full of brood, which required almost all the strength of the bees left in them to hatch it. Both the bees and the brood required food, and part of this was taken from their combs, hence the hives became lighter. When wind is from either east or north very little honey is in flowers, even though the sun shines. You cannot help your bees at present to gather honey. Your aim should be to get your stocks well prepared for winter, and super them next year instead of taking swarms from them.

CUTTING A HIVE FROM EKE (*Comber*).—Your proposal to cut the wooden eke (10 inches deep and 8 inches wide), from the old hive, and then place the second swarm hive on the eke with a view to make a strong stock for another year, and also get a little honey for present use, does not meet with our approval. The eke is too narrow for a stock hive, and probably half of the combs in it are drone combs, as the eke was filled this spring. In detaching the combs from the top hive some of them may fall, and in uniting the two swarms as you propose one of them might be wholly slaughtered. But if all the proposed operations were to be successful the advantage gained would not be worth the trouble. Better drive all the bees into a decent hive and feed them into a stock, or unite them to the second swarm and make a strong one of it. Your aim should be to get rid of all narrow old hives, and have your bees in good roomy ones. If you cut the hive in two parts let the operation be done when the other bees are not flying about. Evening, too, is the best time for uniting swarms. Driving can be done at all hours of the day.

PRICE OF HONEY (*Ev.*).—In ordinary seasons the price of honeycomb is

1s. 6d. per lb. In seasons of scarcity it is readily sold at that price, but in times of abundance the price has to be lowered. Super honeycomb ranges in price between 1s. 3d. and 2s. per lb.

BEES LEAVING THEIR COMBS (*Charleville*).—In the absence of sight it is impossible to say why your bees left their combs and brood and clustered on the outside of their hive, and preferred to bear a drenching rain rather than go inside. They clustered outside before the hive had been swarmed artificially, and after the swarm was removed almost all the bees left in the stock hive preferred the outside. The smoke used in swarming was not the cause of this. We have never known bees act as yours have done in the absence of foul brood. This terrible disease often causes bees to cluster on the outside of their hives, both before and after swarming. Sometimes when the rays of the sun strike hives and raise the internal heat too high, even to the softening of the combs, bees seek air and protection outside.

RHUBARB WINE (*G. D.*).—We published a recipe in the *Journal of Horticulture* on August 2nd last year.

BLACK CURRANT WINE (*F. F.*).—Take dry and ripe black currants 70 lbs., loaf sugar 10 lbs., water sufficient to make fifteen gallons, brandy two bottles. Bruise the fruit in a tub, then add the water, allowing it to stand for twenty-four hours, stirring it occasionally; then draw off the liquor, pressing the fruit; boil the whole for a few minutes, skimming all the time, then add the sugar, and when the liquor has cooled to 75° put it into a cask with yeast and leave it to ferment. At the expiration of fourteen or twenty days the spirit is to be added and the wine bunged up and left for three months, when it may be bottled for use.

REMARKS.

24th.—Fine clear morning at 5 A.M., dark and foggy at 8, cloud by 9; showery from 11.50 till 1 P.M.; sunny afternoon; thunder at 5.16, lightning and thunder at 5.50, heavy rain 5.46 to 5.52 = 0.11 inch; damp evening.
25th.—Showery morning; sunny and bright from 1 P.M., dark clouds at 4, shower at 4.30; fine evening.
26th.—Cool pleasant morning; cloudy afternoon; slight rain at 9 P.M.; lightning and thunder from 10 till 11 P.M.
27th.—Fine day, cloudy at intervals; very fine evening.
28th.—Dull morning, heavy clouds with every appearance of a storm, but none came here; fine sunny afternoon; beautiful evening.
29th.—Fair morning, cloudy and dull-looking after 11 A.M., heavy shower at 3.35 P.M.; fine evening.
30th.—Fine morning, sharp sudden shower at 0.10; fine rest of the day, but dull heavy-looking clouds.
Cooler and damper, with occasional thunderstorms, but none heavy here.—G. J. SYMONS.

COVENT GARDEN MARKET.—JULY 31.

THOUGH the London season is over there has been a brisk demand for hot-house fruit, and prices have been well maintained. Soft fruit are nearly finished, and large buyers are off the market, consequently business will be quiet for a short time till we get a better supply of Plums and Apples.

From observations taken near London during forty-three years, the average day temperature of the week is 74.5°; and its night temperature 50.1°.

CULTURE OF CUCUMBERS IN WINTER.

TO have Cucumbers in the winter months the plants must be now strong; at any rate they must have been raised from seed sown not later than the middle of July. Assuming that the plants are now in small pots, let them be shifted into larger, and have all the light and air possible in fine weather; with a steady bottom heat and with proper care they will be ready for planting out by the middle of August. If the weather is fine much fire heat will not be necessary, but if wet unfavourable weather should prevail after the middle of September fire heat is then indispensable.

Cucumbers in winter are always best trained on trellises. I do not think it matters very much what kind of house is used for them, whether lean-to, half-span, or span-roofed, but it should be in a position to receive all the sunlight possible, and also be sheltered from the north and east winds. The glass should be kept washed clean to admit of a maximum of light during the dull days of the year. I have always found Cucumbers do well in a compost of light turfy loam with a little well-decomposed manure mixed with it. The soil should be used in a rough state—i.e., not sifted.

When planted out give air on fine days, in order to secure short yet vigorous growth. Attention should be paid to the training of the shoots to the wires, which should be a foot or 15 inches from the glass, and as soon as they reach part of the way up the points of the shoots should be nipped out, they will then soon produce laterals, and the fruit then will make its appearance; the laterals should be stopped at the joint beyond the fruit. If the plants grow very vigorously a thinning-out of the shoots will be necessary, for a few strong healthy shoots in winter are better than a large quantity of weak growths. It is best, too, if they should be very prolific in fruiting, to thin the fruit, for if allowed to bear too freely in the autumn months they will not be in such good condition for fruiting during the winter. Good waterings should be given as required, the water being of the same temperature as the house they are growing in. A steady regular bottom heat of 75° to 80° should be maintained. The top heat must be regulated according to the state of the weather. A temperature of from 65° to 70° by night and 70° to 75° by day, with an increase of a few degrees by sun heat, will be a safe one; and on all fine days a little air at top should be given, for if this point be neglected mildew will soon make its appearance, and if it does flowers of sulphur should be lightly dusted on the parts affected, and sulphur also should be rubbed on the pipes.

Evaporating troughs should be placed on the pipes to give off moisture, and weak liquid manure if put in them is very beneficial to the well-doing of the plants. Gently sprinkling the foliage with tepid water during the mornings of fine days helps to keep red spider down; the walls and floors should also have water sprinkled on them two or three times a day. Air should be given very

cautiously when cold winds prevail, but a little is necessary on most days if only for an hour to cause circulation and prevent stagnation of moisture. As the plants grow and roots increase layers of rough turf should be placed on them, and in the spring as the days lengthen weak liquid manure will prove beneficial.

If a stock of plants has not been raised from seed there is yet time to have plants for winter by layering some shoots; or a plan I have found equally good is to take some 60-pots, knock the bottoms out with a hammer, then place a young shoot through the pot and stand it level on the bed so as to be convenient for watering it, then fill up the bottomless pot with soil, leaving of course a few inches or a few joints of the extremity of the shoot above the soil. If all is well the shoot will be rooted in a fortnight, when it may be severed from the parent plant and kept shaded for a few days, when it may be potted-on into a larger pot, or if the place is ready for it plant it out.

As to sorts. The question is sometimes asked, Which is the best sort of Cucumber to grow? There is undoubtedly a large number of good varieties in commerce now, but most gardeners have not the convenience or even the desire for growing more than one or two, so long as they are productive and of good quality. Tender-and-True and Osmanton Manor have the reputation of being good varieties both for winter and summer use, but as I have never grown them I cannot speak of them. A few kinds I am well acquainted with I can speak of.

In January last a span-roofed house 30 feet in length by about 12 feet in breadth was planted with twenty-three plants, one plant of Dickson's Imperial Frame and eleven each of two other kinds—Cox's Volunteer and Rollisson's Telegraph. The latter two were both sown the same day, and had equal treatment. As to earliness, Cox's Volunteer proved the best, I having cut from it a fortnight earlier than from Telegraph; both proved very productive, but the latter produced the best fruit and continued bearing well the longest. In May another span-roofed house that had been used for bedding plants adjoining it, and of the same dimensions, was planted with four plants of Masters' Prolific, four of Cuthill's Black Spine, the rest all Telegraph—about twenty-four plants altogether. Very little fire heat was used for this house, and the plants have been in full bearing for a long time. Telegraph has been decidedly the best, having yielded at least 25 per cent. more fruit plant for plant than any of the other sorts, and judged from a commercial point of view it has been decidedly the best.

Those who have not a house for early Cucumbers in spring and have to resort to hotbed culture should try Streatham Hero. I have found it very early. This variety and Telegraph I have planted out the same day on the same hotbed, and the former has been cut from ten days sooner than the latter; but Telegraph had by far the best fruit and continued in bearing longer. If I were restricted to grow only one variety for spring, summer, autumn, and winter use I should grow Telegraph, for out of many hundred fruits I have cut this season it has been by far the best for productiveness and quality, and I can fully

endorse what has been written by many others, that this is a variety second to none.—A. HARDING.

HERBACEOUS CALCEOLARIAS.

FOR providing a display of these beautiful greenhouse flowers next May and June seed must be sown as soon as possible after the present time (August 1st). If sown much sooner the plants are apt to become too large before winter—that is, if they are shifted on regularly as the pots fill with roots, while if they are not duly potted the plants become stunted and fall a prey to insects. The stems also when the plants are kept in a root-bound state not unfrequently become hard and woody, and after the plants have been shifted in the spring they occasionally die outright. Some mysterious "disease" is then supposed to have overtaken the collection, but in three cases out of five the evils that occur are due to some error of treatment committed, it may be, some months before its effects are seen, or at any rate before they assume a serious phase.

Calceolarias, like Celery, love a cool moist atmosphere, and grow most rapidly during the autumn months. They should be kept steadily growing, also, through the winter, and in the spring when they are given their final shift they will again move with great vigour, and in due time will give a rich return for all the attention that has been bestowed upon them.

It is wonderful that a seed so small as that of the Calceolaria should germinate and develop in the short space of ten months into a plant so massive and gorgeous—a plant, for instance, a foot high having a dense head of flowers 2 feet across, a sturdy main stem as thick as a man's thumb, and an amplitude of luxuriant foliage obscuring half the pot. Hundreds of plants of that type are each year produced, but only by having received unremitting attention on the part of the cultivator. It is not any great amount of skill that is required to grow Calceolarias well, the secret of success is to be found in the paying of close attention to simple details of culture throughout the whole period of the plant's growth.

A few errors somewhat common in Calceolaria culture may, perhaps, be pointed out with profit to some who are essaying the culture of these handsome flowers. They are—1, Sowing the seed too soon and too thickly; 2, Deferring pricking-off and potting the plants unduly, and permitting them to be overcrowded; 3, Allowing insects to gain a footing on the foliage; and 4, Placing the plants in a structure where the atmosphere is too warm and dry, and where they too often suffer by not being watered sufficiently copiously, yet intelligently.

Having pointed out the danger, a safe course may now be sketched. It is as follows: Drain some pots or pans well, and protect the drainage with a layer of moss or clean fibre; fill them within half an inch of their rims with light, rich, sifted soil. If it is lumpy the young plants cannot be removed without having their roots broken. Half of the compost may consist of very old manure crumbling to decay, and the other half of loam with silver sand added according as the loam is light or heavy. If old decayed manure cannot be had, leaf soil will do for mixing with the loam; at any rate the compost must be light and tolerably dry when used. It must not be pressed into the pots very firmly or the tender radicles of the young plant will not penetrate it freely, which is a fertile cause of failure. Water the soil thoroughly, twice if required, an hour or two before the seed is sown. Sow very thinly and do not cover with soil, but keep the surface dark and moist, and every good seed will germinate. A proper place for the seed pans is the most cool and moist place that can be found in the open air, such as on the north side of a building, but not under trees. Place a square of glass across the pan, and over the glass a piece of slate, or the pan may be placed under a handlight or in a small frame to be kept well shaded for a week. The moment signs of germination are apparent light must be gradually admitted, and in a few days no shading whatever must be employed. The soil must be kept regularly moist yet must not be watered, a far preferable plan being to place the pots or pans in large saucers containing a few inches deep of water, and the proper moisture will be secured. In dark, close, moist frames even that precaution is not necessary, as evaporation being reduced to a minimum the soil will retain sufficient moisture for the germination of the seed. When the seedlings appear water must be given carefully yet sufficiently. It is best to pour it very gently round the sides of the pan and let it float over the surface of the soil in sufficient quantity to percolate the entire bulk. Frequent dews, that are so

commonly indulged in, keeping the surface moist while the soil below is dry, constitute a fertile source of the plants damping-off. Thin sowing has been advocated, and it is highly important. It means that a small packet of seed such as is ordinarily sold for 2s. 6d. must not be sown in a 5-inch pot, but in a pan at least a foot in diameter. The plants will then come up thinly and will assume a sturdy growth from the beginning, a character which with good culture they will retain throughout their career.

The after cultivation of the plants is easy. As soon as the seedlings can be handled transplant them an inch or two apart in boxes of light rich soil, place them in a frame, keep them moist, shade for a day or two until they emit fresh roots, and then allow them light and air freely. Just before the plants touch each other pot them, using now somewhat heavier and unsifted soil, potting rather firmly but not hard. Immediately the roots are seen to be fairly active, yet before they adhere to the sides of the pot, shift them into larger, the shift being just sufficient to enable the work being done comfortably. At each potting the soil may be somewhat heavier than before, and when placed in their blooming pots it may consist of two-thirds of rich and rather strong turfy loam and a third of very much decayed manure, mixing with each barrowful of the compost a 7-inch potful of bone dust, and similar quantities of soot and clean silver sand. At this potting the soil should be made decidedly firm. Firm potting promotes firm sturdy growth, light potting longer and more succulent growth. At all times the plants must be handled carefully, and not a leaf must be broken during the operation of potting, but a few of the lower leaves may be removed if it is thought necessary to better induce the emission of roots from the stem.

Watering must be carefully practised, especially after each potting and when the soil is rather heavy and firm. Before being potted the balls of the plants must be decidedly moist but not wet, and the soil must also be in the same wholesome state as to moisture. The pots must be well drained, and the drainage well protected from soil particles, or the crocks may almost as well be outside the pots as in.

Until October the plants may be grown in frames facing the north, the lights being removed during all fine nights, so that the plants receive the night dews, which they enjoy greatly. The pots should be placed on ashes, a sharp look-out being kept for slugs. Early in October the plants should be placed in frames having a southern aspect, and there they may remain until severe weather sets in, when they should be removed to light houses; or with care and due protection they may be wintered in frames if better conveniences are not afforded. In spring, as the days lengthen and heat increases, let them have light, air, and water in abundance; they will seldom require shading, and their shoots, not even the central shoots, will rarely or never require stopping, but the plants will branch naturally and form level heads of bloom. When the flower buds are fairly visible water the plants with weak clear soot water twice or thrice a week. The soil should never be so dry that it crumbles to the touch.

And now to one of the most important points of all. If success is to be achieved an insect must never be seen on the plants. If you can see one there will be twenty others that you cannot see, and if plants are once allowed to be infested they can never be cleared without sustaining injury. As soon as the plants are fairly established after each potting fumigate them lightly, and in the spring fumigate them once a fortnight. A very little tobacco or tobacco paper is requisite, as all that is wanted is to keep the odour of smoke about the plants, and insects will not then attack them. That is not only the most effectual, but is the most economical mode of fumigating.

It is by carrying out the above-described practice in all its details that has enabled plants being produced which have won much admiration, and which have secured honours at public exhibitions. All seedsmen of reputation take care to sell good Calceolaria seed; let it be purchased at once, and be sown promptly.—AN EXHIBITOR.

STRAWBERRIES.

FOR some years past I have been making experiments to ascertain which are the best and most productive Strawberries in my garden. I have tried nearly all the best sorts in cultivation and have given them a fair trial, not of one year only, but of three or four years, before I decided on their merits or demerits.

For the past three years there has been an abundant crop,

and the only enemy I fear now is drought early in the season, and then I water. I am generally able to place a dish of Strawberries on the table any day for a month or more, which is all that can be expected on light land. The soil is deep light loam rather poor than otherwise. The following I consider the best—First early, Roden's Early Prolific; second early, Keens' Seedling; main crop, Sir J. Paxton and President; late, Elton Pine. I also grow a few of Myatt's Prolific in a line as an edging, and cover them over with wire Pea guards to keep off the birds; the others I net. Early Prolific and Keens' Seedling I set out 2 feet apart in the rows and 1 foot 6 inches from each other, the rest 2 feet apart each way. If the ground is not rich I should put between the rows some well-decayed manure in November. As a general rule I do not dig between the plants, but keep down weeds with the hoe and hand-weeding.

If the Strawberries mentioned above do not succeed the following might be tried—First early, Black Prince; second early, Vicomtesse Héricar de Thury; main crop, Amateur and La Constante; late, Eleanor.

Whether La Grosse Sucrée is worth continuing I have not yet decided. It was pretty good this year, but last year was the reverse of sugary, and that I expect will be the complaint against it except in a warm climate like France. I have not tried Marguerite, but have heard it is too soft. British Queen and Filbert Pine are good Strawberries, but not suited for light land.

I do not care very much for Eleanor as a late Strawberry. I have grown it two or three seasons, and if it does not do better next year shall not retain it. It is very likely that it requires heavier land.—AMATEUR, Cirencester.

ROSE JUDGING AND ROSE SHOWING.

THE writer of your leading article on page 61 praises the London system of judging and its collateral arrangements. He next proceeds to cite Preston as an instance of the inextricable muddle into which the officials of provincial exhibitions get if they retain their own system, "one," to use the writer's own words, "which is dictated by local fancies, prejudices, or jealousies." Now, I venture to entertain the opinion that the question of success or failure does not so entirely depend upon the adoption of one of the two systems he mentions, open or blindfold judging—the terms themselves are misnomers after all—but whether the particular system as such is efficiently worked or not. The system in vogue at Preston, given at some length by your correspondent, hardly could have been, for one very similar has been followed at the West of England Rose Show, Hereford, for the last dozen years, where no less an authority than the Rev. J. B. M. Camm (I may add also Mr. Baker) pronounces the management throughout perfect.

I will just outline the leading features in our system. Each exhibitor has a through number representing his own identity, and separate numbers identifying each collection given him. These numbers have to be affixed in front of each box. A member of the sub-committee goes round with each set of judges (always three if possible) to explain and direct, together with another official who takes the judicial award to the secretary. This individual sits close at hand in the exhibition hall, whose easy duty it is to write on a card from his entrance book the name corresponding with the number handed in to him, which is immediately nailed on a lathe conspicuously and securely (a very important point) behind each exhibit to which it belongs. This process is quietly and effectually gone through in very little, if any, more time than it takes me to describe it, and from what I have seen and heard this year the Rose Show at Hereford was quite equal to any other, metropolitan or provincial, both as regards quantity and quality. I do not say but that the reverse-card system is the simplest and easiest worked; what I do say is, that when older existing systems work efficiently, let well alone. I am happy to be able to fully endorse your correspondent's remark that complaints are practically unheard of in connection with the awards of the London shows. I must here mention one signal exception (we will say to prove the rule), which took place last June at the London exhibition of the Royal Horticultural Society, and became the subject of very general comment at the time. I refer to an extraordinary case of Rose judging in placing Mr. Jowitt second in twenty-four single varieties to Mr. Hollingshead's first prize. The former gentleman certainly had one signally unfortunate bloom of *Mdlle. de St. Amand* in the middle of his stand, while the collection of the latter was

uniformly weather-stressed and singularly rough, not to say much smaller throughout. As I was looking at this class my old friend, the President of the National Rose Society, joined me and expressed himself amazed at the decision; indeed, so strongly did the Canon feel in the matter, that I know as a fact he conveyed his sympathy to Mr. Jowitt afterwards in a letter.

I cannot quite comprehend the purport of the article on Rose showing by a "LOVER OF ROSE SHOWS," although I thank him for giving me an opportunity of adding a few words on the recent contest for Messrs. Cranston's cup at Hereford between Messrs. Baker and Jowitt, as the writer seems to imply, from what he gathers from "WYLD SAVAGE'S" report, that the latter gentleman was also in this case, as well as in the one I have just mentioned, unfairly beaten, especially as something is added about the desirability of the judges' names being printed in the schedule. I repeat I am only too glad to make still further known the names of the judges over amateurs, for whose appointment I am solely responsible to the exhibitors and the public. I feel sure it is quite sufficient to mention the names, so well known to horticulturists, of the brothers Gater, the clever, experienced, and respected foremen of the Cheshunt and Slough nurseries, supplemented by the valuable aid of Mr. Curtis of Torquay (our veteran rosarian now John Keynes is gathered to his fathers), who has lately so often written in our Rose Journal for the benefit of its readers. All I can say on this point is that there are many with me who would pity the touching innocence of any exhibitor who dared to risk a duplicate Rose in their collection in the belief that these arcades ambo would fail to spot it. No, sir, not one member of the cognoscenti would dream of doubting either their capability or integrity. I say then fearlessly, as all Mr. Jowitt's friends would and did say, that never was there a more gallant struggle, never a more righteous judgment.

May I in conclusion try to throw some light on a "LOVER OF ROSE SHOWS" seeming bewilderment? I fancy he does not make sufficient allowance for the exuberant humanity with which all the friends of "WYLD SAVAGE" know that gentleman to be endowed. Who would not make allowance for one in your reporter's position criticising the merits of the exhibits of two personal friends? George Paul's quaint comparison from the poultry yard, apposite and amusing on some former occasion your writer refers to, was here utterly out of place, although my humble self, who crept *longo intervallo* into a third place, may indeed have been suggestive of the bantam in such big company. But who—certainly not "WYLD SAVAGE"—could find it in his heart merely to give the dry stereotyped names of the victor's collection with the usual off-imaginative variations, and not sympathetically describe (as he can describe) the congenial merits of the gallant loser, most of them being his own specialities, his shapely though smaller blooms, his lovely Teas, his admirable arrangement? Even if the contrast was just a trifle incongruously heightened at the expense of the victor, those faults began and ended, in my humble opinion, with a coarse and aged bloom of Mrs. C. Wood (how exquisitely Cranston shows this Rose!), but surely not such as to spoil his collection. *Victrix causa Deis placuit, sed victa Catoni*. No, "WYLD SAVAGE," you are no Cato, save in your strict impartiality, honoured here just for once in the breach. Rather in the scribbling of your genial pen (and long may Rose shows and our Rose Journal have the benefit of it) can I fancy I hear the distant echoes of those generous Harrow boys, shouting at the close of their recent hardly-won victory at Lord's, "Three cheers for Eton."—THE HEREFORDSHIRE INCUMBENT.

[This article has been unavoidably delayed a week.—EDS.]

STRAWBERRIES IN POTS.

COMPLETE the potting of the runners for forcing purposes as soon as possible, for if this be deferred much longer the plants have not time to make a good growth and form well-developed crowns, which are essential to a satisfactory result. Those potted some time ago should be examined two or three times a day, not necessarily to water them, but to see that none are drooping for want of that element. Give them a good watering overhead, if with a hose-pipe all the better, making sure that the plants have a thorough supply at the roots. A peck of soot to thirty gallons of water is a capital stimulant, and is not relished by worms or red spider. Too much vigour can hardly be given the plants during the next six weeks, but

avoid any stimulant that induces grossness, and in case of the plants making a sturdy growth avoid giving manure water of any kind. The surface of the pots may be stirred lightly with a pointed piece of wood—this is to cause the water to permeate the soil in the pots equally; for if they become dry the soil leaves the sides of the pots, and without a loose surface the water passes between the sides of the ball and pot without wetting the interior of the soil. Remove all runners as they appear; see that the roots do not escape from the pots, but keep them on a hard bottom in the full sun, yet in a position where they will be sheltered from strong winds, which seriously injure the leaves by their rubbing against the rim of the pots. Let every plant have room for its foliage; crowding the plants together affords nothing but bad growths, poor crowns, and disappointment.—PRACTICALIST.

PLANTS IN FLOWER AT BIRDHILL, CLONMEL.

I PAID a hurried visit on the 31st ult. to the gardens of the prince of Orchid growers in this locality, George Gough, Esq., at his picturesquely situated residence near this town. The situation for a garden, grounds, and surroundings might form the *beau idéal* for a landscape gardener; but to this I hope to return another time. At present the readers of the Journal may be interested in some notes I took of the Orchids at present in bloom, with a collateral reference to a few other plants. The latter were kindly pointed out by the proprietor, and I was shown over the grounds and houses by the head gardener, Mr. John Lonergan, a promising young man, who has a rare opportunity of becoming acquainted with all the novelties in the floral world with Mr. Gough, for no sooner are such announced than you generally find them at Birdhill.

The new Orchid house first deserves a passing notice. It has been erected under the immediate supervision of the owner by a local man of considerable taste and experience, and certainly has all the recommendations pointed out in the Journal by Mr. Luckhurst, page 62, "combining strength, lightness, and soundness with a good method of ventilation, staging, and heating, the materials and workmanship being honest, strong, and true." Here in a brief sentence are the most desirable points requisite in such structures. The house is, say, 50 feet long, span-roofed, and facing south-west. A peculiar feature is having the front sashes painted green. This, besides shading the plants, throws a soft mild light over the house. The plants that immediately on entrance catch the eye are a fine example of *Dendrobium Devonianum*. This was, I remember, in flower last May, and I now ascertain it has produced 220 splendid blooms. Just opening into bloom was a fine specimen of *Vanda tricolor*, a native of Java, and very promising. Another well-developed plant is *Disa grandiflora*, very healthy, but somewhat smaller than the one shown by Mr. Speed from Chatsworth (*vide* Journal of the 25th). An Orchid of considerable merit now flowering profusely is *Lycaste cruenta*, a native of Guatemala. No section is so largely represented here as the *Odontoglossum*. Those now flowering are *O. crispum*, a profuse bloomer, but liable to sport its colour; *O. Roezlii* and its charming variety *alba*; *O. triumphans*, *O. Uro-Skineri*, and best of all *O. vexillarium*. This is a young plant procured last September from Chelsea, the flowers of which are coming out large and splendid. It is evidently one of the best varieties of the species; and this, too, is the opinion of Mr. Gough, who is in this respect a connoisseur of superior judgment. The flowers are generally rose-coloured; this one has a yellow centre softly shaded to rose towards the margin, and is flowering finely in a cool partially shaded conservatory.

The Begonias at Birdhill are in the greatest variety; you find them in every house and of many hues, and even bedded out. I now specially refer to the tuberous kinds. The number and varieties are owing to the successful hybridisation carried out by Mr. Lonergan under the direction of Mr. Gough. One variety was particularly striking, the result of a cross between *Valourous* and *Camoens*, and to which has been given the appropriate name of *Bonfire*; colour dark vermilion shaded softly to crimson.

At present flowering in the stove are *Anthurium crystallinum* and *Cissus discolor*; and the good and sweet old greenhouse plant, *Rhynchospermum jasmynoides*, is represented by a handsome specimen trained on an oval wire trellis.

A reference to Mr. Gough's plants would be incomplete without noting two very remarkable Ferns in cases—*Todea* (*Leptopteris*) *superba*, and two plants of the well-known *Kilarny Fern* (*Trichomanes radicans*), quite models of healthy

growth. The former is a native of New Zealand, and to which no description could do justice. The fronds are over a foot long and of a bright green transparent texture, gracefully drooping. After a refreshing turn in the cool and charmingly constructed grotto where boating parties from Clonmel are allowed to picnic, after a pull up the river I leave, purposing to return to this attractive scene and subject again.—W. J. M., Clonmel.

GRAPES SCALDING—SEEDLESS BERRIES.

SINCE duty was taken off glass an impetus has been given to the erection of horticultural structures; thin crown glass has been supplanted by sheets of much greater thickness, and the panes or squares have been much increased in size, doing away with no inconsiderable extent of sashbar and a great many opaque laps; in other words, the light admitted to a house constructed upon modern principles is very much greater than was formerly the case with the old-fashioned system of heavy rafters, close sashbars, and small squares. There is no doubt of the advantage of the modern system in all structures from October to March inclusive, but in summer it is questionable whether large panes of clear glass have not much to answer for in scorching, attacks of red spider, and in the scalding of Grapes. Grapes scald only when the solar rays are most powerful—i. e., in June, July, and August, and in no instance have I seen a scalded berry in any other month. This would point to the evil being due to excessive solar heat aggravated by imperfect ventilation.

As conditions predisposing to scald I may mention grossness of growth, induced not so much by rich borders as by a close, moist, ill-ventilated atmosphere, which gives to the fruit the character of the foliage—viz., gross and watery. Scalding usually follows a dull cold period. When the atmosphere of the house is surcharged with moisture the berries swell rapidly, but in dull weather there is little or no evaporation going on from the foliage or berries; the skins of the latter are thin, having a deep green appearance, as also has the foliage. Upon a return to bright weather the house is suddenly heated, the leaves give off water, and the fruit also, but the latter cannot do so nearly so rapidly. They become heated by the surrounding atmosphere, for the direct rays of the sun are not necessary to cause scalding, and the whole surface of the berry affected is scorched, and then shrivels and falls. This is a bad case of scalding, due entirely to too low a temperature previously, and insufficient ventilation accompanied by too much moisture.

There is not much difference between this form of scalding and that which affects the Grapes in spots at the upper side of the berries or that side exposed to the sun which is somewhat less disastrous and easier of avoidance. The remedy for this as well as the preceding is, when the berries have stoned to afford a little ventilation at night and fire heat to maintain a temperature of 70° to 65° night, and afford very liberal ventilation by day, not allowing the temperature to rise above 80° without full ventilation, increasing it from 70° with increased sun. In order to save fuel fire heat is often only afforded when the Vines are being started into growth and when the crops are finishing, the Vines in the interim being solely dependant on solar heat, and at the same time no difference is made between the moisture afforded when fire heat is employed and when it is not. This tends, particularly in a dull period, to promote succulent growth and great leaf-development, which frequently results in overcrowding, and the fruit is then much liable to shank and scald. Grapes never do so well as in a house with a circulation of warm air, and when the fruit is ripening, rather dry.

Muscats ripening early in June sometimes scald, which is due to the want of that free day ventilation that is given to crops at a later period. When Grapes must be pushed to come in at a given time there is no alternative but two—First, to have a large extent of heating surface, so as to admit of free ventilation whilst maintaining the requisite temperature; or, second, to afford a slight shade, as that of hexagon netting, when the sun's rays are fierce, particularly after a dull period. These observations are given upon the assumption that the foliage is ample and fully exposed to light, not at one time crowded with laterals and at another time letting in a flood of light by removing the laterals by the barrowload; also that the atmospheric moisture is regulated by the weather. Vines, as a rule, receive too much atmospheric moisture and a too scanty supply at the roots.

Seedless berries are a consequence of immature wood and imperfect impregnation, and is more frequent in the case of those Vines that are very luxuriant. Thoroughly ripened wood and plump well-developed eyes usually afford bunches that set the berries well. Muscats, for instance, have the wood well matured set well in a night temperature of 60° to 55°, whereas those having the wood imperfectly ripened set as indifferently in one of 75° to 70°. Some Grapes, such as Black Damascus, Lady Downe's, Mrs. Pince, Black Muscat, and Muscat of Alexandria, are notoriously bad setters, and have a number of stoneless berries. Setting is promoted by brushing the bunches lightly when they are in bloom with a camel's-hair brush, or gently tapping the footstalks of the bunches with the finger so as to aid in the distribution of the pollen, and the maintenance during that time of a medium temperature of 75° to 70°; but as before stated, thoroughly ripened wood is of primary importance.—G. ABBEY.

ORIGIN OF LORD SUFFIELD APPLE.

I HAVE been anxiously waiting for an answer to your query as to when and where Lord Suffield Apple was raised; but I did not see a reply in my weekly friend, consequently I have made inquiries and learnt from an old inhabitant of Taunton, a small village within a mile of Ashton-under-Lyne, that Lord Suffield was raised by Thomas Thorpe, a hand-loom weaver of Boardman Lane, Middleton, near Manchester, but he could not give me the correct date of its raising, but that it was let out in 1836 or 1837, himself purchasing three buds from Thorpe at 3d. each in the year 1840, a tree of which stands still in his garden. The Apple was called Lord Suffield on account of Lord Suffield being then lord of the manor of Middleton.—FIR BOB.

A TRIPLET OF ROSE SHOWS.

THE wide-spread popularity of the Rose is to be measured in various ways. The innumerable host who grow the flower; the enormous quantities sold every year by a large number of growers; the acres that these growers cultivate; and last, not least, the exhibitions at which it is sometimes the sole flower exhibited, and at others where it is the *pièce de resistance*—all bear witness to the fact that it is the most popular of all flowers. And of these exhibitions it is not merely our great shows which bear witness to it—the great National Show at the Palace or at Manchester with its ten thousand visitors—but places where one would hardly expect to find it vie with each other in offering homage to the Rose; and having lately assisted at three of these minor exhibitions, a few notes as indicating the progress in favour of a flower dear to most readers of the Journal may not be unacceptable. Never would one more like to realise Sir Boyle Roche's notion of having the power of being in two places at once than during the Rose season. I was, on account of this unfortunate inability, unable to be present, as I had been invited, at Newcastle, Reigate, Maidstone, &c., my duties to the National hindering me in some cases and previous engagements in others, and so one had to be contented with seeing less. My first visit was to

UPPINGHAM,

A very quiet, quaint, old town in Rutland, out of the way, and might perhaps never have been known to the outer world but for the energy infused into an old institution by the Rev. E. Thring, who, undertaking the charge of the Grammar School when there were twenty-seven boys, has by his wisdom, indomitable energy, and capacities as a leader of men (and which is perhaps as difficult, of boys), made Uppingham School famous, and has done, what perhaps was never before attempted—migrated with his whole school when an epidemic of typhoid broke out, carried them away to Borth, and brought them back again when there was a clean bill, the school suffering no way in either prestige or numbers by its strange vicissitudes. Amongst the old institutions of the town is what is called the Feast Week, and it was a happy thought to give the holiday folks an opportunity of rational enjoyment by holding a flower show on one of the days. This was the second time that it had been attempted, and I hope that both the extent of the exhibits and the number of visitors will warrant its continuance.

The Show was held in the cricket ground belonging to the school, the authorities of which were deeply interested in the success of the day, and the Exhibition was arranged in three tents. It will not be needful to enter into any detailed account of it; suffice it to say that the large plants exhibited by Mr. House sustained his well-earned reputation, and that cottagers exhibited very creditable collections. The Roses were mainly contributed

by Mr. House of Peterborough amongst nurserymen, and by the Rev. W. H. Jackson of the Manor House, Hambleton, amongst amateurs. Amongst the blooms exhibited by the former were fine examples of Charles Lefebvre, Horace Vernet, Alfred Colomb, Marguerite de St. Amand, Maréchal Niel, John Hopper, &c.; while Mr. Jackson's blooms, of good average size, were clean and regular in shape. Amongst them were many of the old favourites as well as some of the newer varieties. The Rev. G. Christian also exhibited some good flowers, especially Teas, and the interest excited in the stands evidently showed that a Rose fever was becoming prevalent in the neighbourhood, far better than the typhoid which sent Uppingham to the sea. It was a very hot day, and I was not therefore sorry that I had arranged to leave for Scotland by the night train, although it was rather hard work, but at ten o'clock the next morning I found myself at

HELENSBURGH,

Where a Rose show *pur et simple* has been organised and under the indefatigable management of Mr. Galloway, of the firm of Galloway & Graham, is evidently taking the leading position in Scotland. I recorded the Exhibition last year, and showed how Messrs. Paul & Son and Mr. Cant met in friendly rivalry, and how I endeavoured very earnestly, as a Secretary of the National, to impress upon them the need of alteration in two particulars—one that of confining their Show to one day, the other of exhibiting their Roses without any added foliage. This year they have adopted both of these alterations, and in one to the manifest advantage of the Show, while I hope the other will be equally so to its financial condition. As I have already mentioned, they adopt here a very original plan in the setting-up of their Roses. The stages are arranged as tables with tubes in them, and each exhibitor, instead of putting up his own stand, has to place them in the spaces allotted to him. It is to my mind an inconvenient and undesirable plan. It certainly puts all in one sense on an equality, but then it is liable to create confusion and give no opportunity, in the case of closely contested stands, of comparing them; and all who have to judge Roses know often how very desirable this is, and how it often settles a disputed point. Nor was exact uniformity attained, as the flowers of one exhibitor were placed some 2 inches high out of the tubes, and I cannot but think that a change would be hailed by most exhibitors as a boon. Mr. Cranston, who seems this year to have been ubiquitous, entered the lists alone of English growers; and Mr. Dickson of Newtownards, Ireland; Messrs. F. & A. Dickson of Chester, so that it was truly an international contest; and in this case the laurels went, and deservedly, to Ireland, for the collection sent from there by Mr. Dickson of Newtownards was a really grand one, as its placing Mr. Cranston second will prove. But let it be said that the latter was not in good form; his Roses lacked freshness, whereas Mr. Dickson's were beautifully fresh and bright. Amongst them is a variety I have not seen elsewhere—Alexander Dickson, a fine showy flower, something in the style of Madame Schmidt. What was especially noteworthy here was the manifest improvement that had taken place amongst the local amateurs, and this is the most satisfactory result that the promoters could expect. To obtain external help is well enough, but after all what one wants to see is local growers stirred up, and I am sure this has been the result here. I have been present at three of their exhibitions, and beyond any manner of doubt this was the best of the three. The arrangements for the Show were excellent, the Judges were admitted in good time, and the kindness and courtesy of all concerned in the Show made everything agreeable. I cannot forbear here telling a story relating to myself. We were sitting together in the evening in the garden of my friend Mr. Galloway looking at his fine beds of *Gladiolus*, and at the same time enjoying our tea, when one of the friends present said, "I must tell you what happened to me some time ago. I was in the garden talking with my brother [I think he said] with the Journal in my hand and I said to him, 'There is something from 'D. Deal,' in the paper to-day.' The old servant overheard me, went into the house, and said to her mistress 'Eh! ma'm; but the maister says ther's something about the *deil* in the paper to-day.'" The third Show was

NEWTON STEWART,

And I have a peculiar interest in it; it was originated by one who was then a perfect stranger to me. He knew me only then by the Journal, and when I received a most pressing invitation from the Rev. G. W. B. Mackenzie to go to Galloway to judge at a Rose show I did not think how much I should afterwards be mixed up with it. Together we remodelled the arrangements, he by his energy sustained it, and I thought when he went to far-off Ceylon that there would be an end of it and my intercourse with Newton Stewart. I was heartily glad, then, when I was asked once more to take my place to meet its kind and genial inhabitants. The Show was held on the 23rd (the same day as the National Carnation and Picotee Show at South Kensington, at which I was consequently unable to be present), and here again the same result was obtained as at Helensburgh, a very marked improvement in the local exhibits both amateur and professional. Messrs. Dickson of Newtownards again contributed a

very fine lot of flowers; and Mr. Smith of Stranraer showed such blooms as he has never before exhibited. In Mr. Dickson's stand Richard Wallace, Duchesse de Vallombrosa, Star of Waltham, Sophie Tropic, Sultan of Zanzibar, Alexander Dickson, John S. Mill, and Mons. E. Y. Teas were especially fine, while his box of Teas, including Reine de Portugal (rarely seen), Homère, Smith's Yellow, another uncommon Rose; Souvenir d'un Ami, Souvenir d'Elise, &c., was excellent. In Mr. Smith's stand Oxonian, Madame Thérèse Levet, Baronne de Rothschild, Mons. Fournier, Prince Arthur, and Charles Lefebvre were especially good. The gardeners and amateurs contributed some excellent stands, especially considering the season. Such a summer has not been known in Scotland for twenty or thirty years—no rain for nearly two months, the burns nearly all dry, and the rivers very low. All this combined with most scorching weather deprived many an exhibitor of his hoped-for blooms; but there was a great improvement in the quality of the stands, fewer bad Roses, and many very excellent blooms which would not have discredited any show. I must here also tell a wee tale which I was permitted to tell at the dinner. I have said that Mr. Mackenzie the founder of the Show had gone to Ceylon. Well, a letter had been received from him a few days before I was there, in which in speaking of his neighbours, who he said had been so kind, he added, "— has given me a pig, and now I shall have plenty of (pork and sausages? oh, no!) good manure for my Roses." I think the most thoroughly rosarian view of the gift of a pig I ever remember to have read.

One great treat I enjoyed was the inspection of Mr. Vernon's new patent toilet ware, which is really most beautiful and elegant. One treat I did *not* enjoy was in stepping out of a drag I jarred my ankle, which will give me a memento of Newton Stewart for some time to come. I cannot close these rambling notes without expressing my deep sense of gratitude for all the kindness I have received in my ramble, and have again to bear witness to the heartiness of Scotch hospitality.—D., *Deal*.

A PLEA FOR TYDÆAS.

DURING the hot months of summer it is not easy to find plants for keeping greenhouses and conservatories gay without arranging the same kinds of plants under glass that are growing in the flower garden. While such plants as zonal Pelargoniums are admissible for indoor decoration in summer, some of the better and newer varieties being indispensable, it is not well that they should unduly preponderate. A change is always refreshing, and the eye generally rests with more satisfaction on plants in houses when they are not merely duplicates of plants growing and flowering in equal or better condition in the open ground.

Amongst plants that are extremely attractive when well grown and displayed under glass, and of which there are at the same time no representatives growing and flowering outside the houses, are Tydæas. The varieties of this genus are extremely diversified in colour and many of them are very beautiful. The lighter colours are remarkably chaste and the darker varieties intensely rich. These plants, however, are not exclusively summer flowers, for by starting the plants at different periods they will produce flowers "all the year round." In the depth of winter I have seen them much admired, but not more so than during the sultry months of summer, when, as before observed, they afford an agreeable change from the ordinary popular flowers that are usually grown in large quantities both in and out of doors. The varieties are very numerous, and some of them are not particularly striking, but the following half-dozen, selected from a collection in Messrs. Rollisson's Nursery at Tooting, are distinct and good.

Rosenovia Hanstenii.—Creamy white, with lilac and purple stripes, and rose blotches on the lobes. The flowers are large, and the plant is a strong grower, but does not flower so continuously as some other varieties. Good.

Rosenovia ornata.—Tube scarlet; upper sepals of the limb bright scarlet, lower one light amber spotted with scarlet. Very rich and glowing.

Venusta.—Flowers of excellent shape and good substance; colour purplish lake with crimson veins and spots. Very distinct and attractive.

Sape.—Intense velvety crimson, with crimson-purple spots; flowers large, well formed, and remarkably rich.

Robert le Diable.—Deep crimson, with velvety and nearly black veins and spots. A very dark and fine variety.

Madame Heine.—Although this is mentioned last it is quite one of the best and most useful varieties in cultivation. It has been previously alluded to as being considerably grown

and much admired at Kew. Its colour is rosy crimson covered with a delicate network of veins and spots.

Few plants are of more easy culture than Tydæas. During the growing season they require the same general treatment as Achimenes, but, unlike those plants, they must not be totally dried off during the resting period. It is probably to over-dryness in winter, or when not growing, that the loss of many Tydæas is attributable. Keep the soil moderately moist and the plants are safe.—J. W. S.

THE MADRESFIELD COURT VINE.

I HAVE made several experiments with this fine Grape, as, through its tendency to crack, it had become useless here. For several years I grew it inarched on the Black Hamburgh and Muscadine, these Vines being on their own roots—that is, there were four Vines. This inarching prevented the berries cracking, but they all became round and smaller than the Madresfield Court on its own roots. My last experiment was to inarch the Vine—that is, the Madresfield inarched on the Black Hamburgh—on a stout rod of Glendinning's Seedling, a strong-growing variety with large fleshy leaves, the berries being semi-oval, thick-skinned, and amber when ripe. The effect of this experiment has been to change the berries back again into their oval shape, considerably larger than I have ever grown them before and without any symptom of cracking. The Madresfield Court which I inarched on the Muscadine produced round berries precisely the same in all respects as the one on the Black Hamburgh. After a time I cut this Vine off from the Muscadine. For the first year the berries continued to grow round, afterwards oval and cracked.—OBSERVER.

THE ROSE ELECTION.

AS briefly as possible I reply to "WYLD SAVAGE's" strictures. I believe his friend did not reply to the circular; if he did he overlooked the taking several prizes at local competitions as qualification. "WYLD SAVAGE" praised his Roses extremely, founded on their excellence—a plea for giving up a practice that most successful exhibitors follow, and wound up with his success. What more natural than that a returning officer, anxious to secure every qualified elector, should apply, especially when his productions had been praised by so great an authority?

Next, I have never claimed for the election that it was a "guide to leading exhibitors." Why, what could it teach them? They know much more than the election or the returning officer can teach them, and what really is hoped for is to obtain the opinions of these leading exhibitors as a guide to the lesser growers. That it has thus been useful many willingly attest, and to that verdict I look rather than to that of our friend "WYLD SAVAGE," who, his great knowledge and powers notwithstanding, is just a wee bit crotchety, and apt to fire off his arrows without stopping to reflect whether the rebound might not tell against himself.

However, there are thorns enough on some of our favourites which we need not plunge into each other.

Meanwhile I may state that the circular this year has been sent, with but few exceptions, to prizetakers at the National, Alexandra, Hereford, and other shows, and I am quite certain beforehand that the result will not please everybody, consoling myself with the reflection that to others it will prove useful.—JOSEPH HINTON.

It may be in the recollection of your readers that when last year's election was first mooted some correspondents expressed a desire that Teas might have an especial recognition therein. Mr. Hinton's reply was that he could not attend to it then, but if spared to try another year he hoped to do something in this direction. Can he attend to this matter now?

As the general election is to decide the best forty-eight Roses, and as we are never, so far as I am aware, called upon to show more than twelve Teas (distinct sorts that is), I think it could be managed this way:—Name the best thirty-six Roses (Teas and Hybrid Perpetuals) and then twelve Teas in order of merit, the hardest, best growers, and freest bloomers.

I know "WYLD SAVAGE" is very partial to Teas, what does he think of this plan?—A LOVER OF ROSE SHOWS.

THE plan proposed by "WYLD SAVAGE" of obtaining lists of Roses from prizewinners at the great shows is an excellent one. The elections are primarily for the benefit of exhibitors

yet the results are very valuable and have been much acted upon by general cultivators when ordering Roses for the decoration of their gardens, for there is not much doubt but that the varieties placed high on the list as producing the best exhibition blooms are eminently suited also for garden and drawing-room embellishment. The elections, therefore, have been of great benefit to many, and Mr. Hinton has deserved and received the thanks hearty and numerous of almost all those who love the Rose for the labour he has incurred in conducting the elections.

If we are to have another election this year it will certainly, I think, be in the highest degree authoritative if conducted on the principle projected on page 84. It is doubtful, however, that the relative positions obtained by varieties of established merit will be practically altered by the returns proposed. That some change will be made in the case of certain varieties is only what may be expected, but will the change be really useful? The position is this, that although one old Rose may rise a few points and another be placed a few points lower on the scale, still all must be grown by those who grow Roses for the great exhibitions.

The varieties vary with the seasons. Last year Mons. Noman was well shown, this year it was seldom seen; it is, however, low on the list, possibly on account of its inconstancy. Charles Lefebvre and Alfred Colomb, which are placed second and third on the list, have been by no means frequently exhibited this year, although a few fine blooms of them have been staged, yet no one can dispense with those Roses in a collection in the garden. Much finer, and more often fine, have been varieties much lower on the list, such as Mons. E. Y. Teas, Horace Vernet, Beauty of Waltham, Duchesse de Vallombrosa, Jean Liabaud (not in the list at all), Annie Laxton, Xavier Olibo, Mrs. Baker, and some others. The positions of varieties of established merit will vary slightly if their merits are re-estimated every year, but the varieties will still be good and must be grown as heretofore.

What I think is a failing on the face of the elections is the injustice that is apparently done to the newer Roses. However good they may be they are years before they can win a high position in the list, simply because amateurs have not grown them in sufficiently large numbers to be able to assess their merits. What I think is required is a tabulated estimate of the merits of the Roses that have been placed in commerce say during the past six years. New growers of Roses do not want to know which are good amongst the older sorts, they are willing to accept previous returns as to them; but they want to know the comparative merits of sorts of recent introduction for the purpose of adding them to their collections. If a dozen of the principal growers and good judges were to direct their attention to determining the relative merits of new Roses as such, instead changing the positions by a few points of the old sorts, I think the returns would be of great value and interest.—AMATEUR ROSE-GROWER.

NORTH WALLS.

MR. TAYLOR is quite right in supposing that Marie Louise Pear will succeed well on north walls. I have tasted fruit of that excellent Pear which had been grown on the aspect indicated of quite superior quality; also fruit of the Jargonelle grown on the same aspect. It is well worth while trying a tree or trees of those and other early Pears on north walls, at least in the southern and midland counties, and in hot seasons it is very probable that they will produce fruit fully equal if not superior to that ripened in sunny positions—superior by being more juicy and less mealy. But apart from that, trees on north walls afford a valuable succession of Pears of sorts of such short duration as those named when the supply is wholly gathered from trees grown in warm sunny positions.

The question of retarding the blossom of Pears is one of considerable moment, and by no other means can it be done so well as by having a Pear tree or two against north walls. A gentleman has told me that a Jargonelle Pear tree trained against the north wall of his garden has proved more certain in producing crops than a tree on the south wall. Late Pears will, of course, not ripen in such cool positions, but early sorts will ripen there just as well, as will most of the Plums named by Mr. Taylor.

If it ever falls to my lot to again plant fruit trees against a north wall for affording a supply of fruit for a gentleman's family I shall certainly include a tree of Jargonelle, Citron des Carmes, and Marie Louise Pears, and the great bulk of the

wall shall be covered with Plums. Of trees that I planted a few years ago the only Plums this year bearing well are against the north wall; the bush trees and standards in the open garden being nearly barren, while Morello Cherries in the open are bearing quite as well as those against the north wall. If I were called on to cover a north wall in the most profitable manner—that is, with a view of raising the most money by the sale of fruit, I should plant Victoria Plums. No Plum, according to my experience, equals it for such a position. The fruit may not perhaps be quite so fine and highly coloured as fruit grown in the sun, but the trees on a north aspect bear prodigiously, and the fruit is very valuable and is purchased freely in the markets of the midland and northern districts.—A MIDLAND COUNTIES FRUIT-GROWER.

THE BATH AND WEST OF ENGLAND SOCIETY'S SHOW.

THE reply which "AN OLD EXHIBITOR" makes to his own query as to the usefulness of this Show (see page 23), proves that he does not understand its end and aim, and also that if he did he would hardly be prepared to accord it his sympathy, for he evidently can see no good to be derived from a public exhibition of his plants other than in competition for prizes after the usual fashion. To stand first in certain classes is the height of his ambition, and the feeling is unquestionably a laudable one. Nor can the time spent upon the culture of flowers, fruit, and vegetables for such exhibitions be regarded as time lost to an employer, for confined within just limits and devoted to the highest possible development of produce that is really useful, it renders a man more skilful and tends to promote excellence in every department of the garden under his charge. That is the legitimate purpose of exhibitions, and the schedules of prizes issued by horticultural societies may be regarded as good, better, best, according to the degree in which they encourage such purpose.

Unfortunately the common tendency to follow a beaten track obtains a striking exemplification in the schedules of provincial societies. Take any number of them, and you will find such a wonderfully close resemblance that degrees of excellence resolve themselves into pounds and shillings, anything like originality being extremely rare. "How I do hate the everlasting twelve stove and greenhouse plants! I don't believe that more than thirty species are shown during the summer. One sees the same plants year after year, and one seldom, if ever, sees a plant that is very difficult to grow." So wrote a friend to me the other day, and there is undoubtedly much truth in what he says. When one goes to report a show in a familiar locality one knows most of the plants beforehand. The never-failing Crotons, Palms, Ferns, Dracænas, Cycads, come before the public again and again, the prizes are shared by the same three or four, or at most half a dozen, exhibitors year after year, and the affair becomes somewhat tame and monotonous. Visitors come to the show, see, wonder, go away, and forget, for however much they may admire the elegance and beauty of individual plants, they find nothing instructive, gain no hints of culture or knowledge of plants that are really useful, but are rather daunted at the sight of plants so large that a couple of them would fill an ordinary greenhouse. What have they to do with such plants? Of course they can and do admire them, but then they want something more—they want to see plants as rich and rare as you please, but of an ordinary type as to size and form, arranged by skilled hands so as to show their true value and use.

The Bath and West of England Society recognise this want, and have given expression to such recognition by placing full powers in the hands of the steward of the horticultural department, and by the energy and taste of that gentleman afford the public a magnificent display of plants and cut flowers that is quite unique. In the arrangement of the plants full effect is given to the contrast and harmony of colour, to blending form with form, to light and shade, and the result is a superb picture abounding with grace and beauty; or rather it should be said a series of pictures, for as we go up and down the huge tent the eye is arrested by artistic combinations varying at every step, and yet there is a connection and flowing grace running through the whole.

It was my privilege to watch the formation of those artistic plant groups at the late Oxford Exhibition, and as they grew into beauty under the skilful supervision of Mr. Boscawen, his prompt "No, no!" or hearty "Well done!" guiding the work with unerring precision, a lesson of such value in plant

arrangement was given that one could not help wishing every gardener in the district had been there to profit by it. Probably most of them did go at some time during the week with pleasure and some profit, for no thoughtful man could inspect the Show without being impressed by its usefulness. It takes high ground, nothing but what is really meritorious being admitted; the highest standard of horticulture in each district thus being fairly represented. Moreover, no one is made to hide his light under a bushel; every fine plant or group of plants bears the name of its owner and the gardener upon a handsome card placed in a conspicuous position, and adequate remuneration is made to every exhibitor for the time, trouble, and expense of taking produce to the Show.

Surely the managers of horticultural societies generally might take a hint from this and extend the scope and usefulness of their exhibitions by affording space for mixed groups of plants useful for the decoration of a drawing room, corridor, vestibule, or conservatory. Much good might also be done by offering premiums of some kind or other for single specimens or groups of plants limited to certain sorts either uncommon or of difficult culture, of which a list should be given.—EDWARD LUCKHURST.

ROYAL HORTICULTURAL SOCIETY.

AUGUST 6TH.

FRUIT COMMITTEE.—John Lee, Esq., in the chair. Messrs. Charles Lee & Son sent ripe fruit of Lawton Raspberry, to which a letter of thanks was awarded. They also sent fruit of Hampton Court Peach, a form of Grosse Mignonne. Mr. Sidney Ford, gardener to W. E. Hubbard, Esq., Leonardslee, Horsham, sent a seedling yellow-fleshed Peach which was unripe. The following fruit was received from the garden at Chiswick—Galopin, a very large Nectarine of good sprightly flavour, and Duke of Buccleuch Grape. Messrs. Rivers & Son of Sawbridgeworth sent fruit of Advance Nectarine, which was excellent in flavour, as also Pine Apple Nectarine. Mr. W. Thomson of Clovenfords sent a splendid bunch of Duke of Buccleuch Grape weighing 2 lbs. 14 ozs., to which a cultural commendation was awarded. The berries were enormous and of fine colour, and there was no trace of the spot which is sometimes found in it. Mr. John Chater, gardener to Sir Charles Isham, Bart., Lamport Hall, sent a seedling Melon raised between Cox's Golden Gem and Bloxholm Hall, but it was not in good condition. Mr. H. A. Mann, St. Vincent's, Grantham, also sent a seedling Melon which was inferior in flavour.

The following were brought from the garden at Chiswick—Vick's Criterion Tomato, Trebons Onion very fine, four varieties of Beet, consisting of Bassano, Egyptian Turnip-rooted, Nutting's Dark Red, and Richardson's Pine Apple. It is noteworthy that these being all sown at the same time, the Turnip-rooted varieties were almost fully grown and fit for use, but the long varieties were but little advanced and would not be ready for a long time.

Mr. Sidney Ford sent a collection of forty varieties of Potatoes, to which a silver Knightian medal was awarded. A very fine collection of twenty sorts of Cabbages was received from the garden at Chiswick, which evidenced very good cultivation, and a cultural commendation was awarded.

FLORAL COMMITTEE.—Dr. Denny in the chair. The great attraction at this meeting was the numerous quantity of Tuberous flowering Begonias which came from the Society's garden, Chiswick; Messrs. J. Laing & Co., Stanstead Park; Messrs. Veitch and Sons, Chelsea; and Messrs. Hooper & Co., Covent Garden. An exquisite collection of forty-eight varieties of *Gladiolus* came from Messrs. Kelway & Sons, Langport, to which a gold medal was worthily awarded, fifteen varieties of which were Mr. Kelway's seedlings of this season, and three of them received first-class certificates—namely, Telamon, a large flower of good substance with a fleshy ground, and flaked with scarlet with a light throat. Gogonius, an immense flower, measuring 4 inches in diameter and having twelve fully expanded flowers on the truss; the pipes were a red ground heavily blotched with a deeper red, the throat carmine—a very attractive variety. Herios, bright rose flaked with carmine, ivory white throat; very showy and distinct.

Messrs. Laing & Co.'s collection of eighty plants of Tuberous Begonias were much admired, and were nearly all raised from seed sown on January 24th of this year. A few large plants of Paul Masurel, Emperor, and Madame Oscar Lamarche added to the beauty of the background of the group, and the whole collection was most highly attractive and deserved the gold medal awarded to them. Messrs. Hooper & Co. also sent a large collection of Begonias, including Lustre, Paul Masurel, Sedeni, Eldorado, Salmoena plena, and Montrose.

A very interesting collection of seedling Gloxinias raised in 1878 also came from Messrs. Hooper, to whom a silver Banksian medal was awarded. Mr. B. S. Williams, Holloway, also received a silver Banksian medal for a tastefully arranged group of fine-foliaged plants, amongst which were *Crotons Jamesii*, Williamsii, Prince of Wales, and the compact and bushy variety *C. campto-*

phyllus; *Dracenas*, *Caladiums*, numerous Palms, and *Coleus* Lords Falmouth and Oxford.

A gold medal was deservedly awarded to Messrs. Veitch & Sons for an extensive collection of *Nepenthes*, including *Nepenthes Kennedyana*, the only variety found in Australia; *Sarracenia*, *Cephalotus*, *Drosera*, and other insectivorous plants; several varieties of *Begonias*, such as *Begonia Veitchii*, *Roseflora*, and *Davissii*, which illustrated the origin of the various types that are now infused in the numerous varieties of the present day, and a basket of that free-flowering and highly attractive hardy shrub *Hydrangea paniculata grandiflora*; also fine cones of *Araucaria imbricata*, gathered at their Coombe Wood Nursery.

From Mr. Cannell, Swanley, came cut flowers of *Geraniums* and *Verbenas*, which received a vote of thanks. Over two hundred plants of flowering *Begonias* were sent from the Society's garden at Chiswick, and arranged on tables extending the whole length of the entrance vestibule, and amongst the most attractive we noted Moonlight and Sunshine, raised by Col. Clark; *Vesuvius* and *Emperor* (well-known and attractive varieties), raised by Veitch & Sons; *Solfaterre*, by Fröbel & Sons; *Worthiana*, *Oriflamme*, and *John Laing*, by Lemoine; and a double-flowered variety (*Gloire de Nancy*) by the same raiser; *Feu de Joie* and *Eldorado*, raised by Chantrier. The whole of this extensive collection were remarkably well grown and flowered.

First-class certificates were also awarded to Messrs. Laing & Co. for *Begonia* Mrs. Dr. Todd, a brilliant scarlet, large, free-flowering variety, with a good habit; to the Royal Horticultural Society for *Begonia* Chiswick (blush), raised at the Society's gardens; flowers medium size, white inside and blush out, of fine habit and very free flowering. Botanical commendations were awarded to Messrs. Veitch & Sons for *Torenia Baillonii*, and to Mr. B. S. Williams for *Dendrobium Albertisii*, a curious Orchid of no great beauty from New Guinea; it is the first of the New Guinea Orchid introductions that has ever been exhibited. Another very rare-flowering Orchid was sent by Mr. Osborn, gardener to — Buchanan, Esq., named *Odontoglossum Lindenii*, and originally introduced from Columbia. Mr. R. Dean, Ealing, exhibited a very dwarf form of *Golden Feather*, which must become useful for carpet-bedding purposes when better known.

NOTES AND GLEANINGS.

THE violent THUNDERSTORM which swept over the metropolis and its vicinity on Friday night has, we learn, done much damage in parks and gardens. Much destruction has been caused to timber trees, which are now heavy with foliage; fruit has been dashed from the trees, flowers have been despoiled and broken, and gravel and soil have been washed into heaps. A close murky atmosphere has prevailed for several days past, and unless a change speedily occurs the Potato disease is almost certain to set in, it may be with virulence. On the nights of Sunday and Monday the storms continued at intervals, rain falling in places at the height of about an inch an hour. A letter from Lancashire informs us that rain is much wanted there, and that late *Rhododendrons* are drooping and late-planted shrubs are dying by want of water.

— MESSRS. VEITCH'S NURSERIES at Chelsea are at all times worthy of a visit. No one can visit them now without recognising the value of *Yucca recurva* as a lawn and garden ornament of great value. The rows of fine specimens of this *Yucca*, surrounded by groups of hardwooded plants and arranged in the main walk of the nursery, are quite imposing. In one of the cool houses a number of plants of the valuable *Hydrangea paniculata grandiflora*, grown in the open air at the Coombe Wood nursery, are just expanding their flowers. This fine hardy *Hydrangea* should be grown in every garden. Tuberous *Begonias* from the majestic *Monarch* and *Emperor* to the brilliant gem *Davissii* are yet in beauty, but some of them are fading. The rich, glowing, velvety crimson Mrs. Scorer is quite one of the finest; but an older variety, *Sedeni*, is yet one of the most valuable of the section. *Roseflora* and the newer *Queen of the Whites* are a distinct pair and very free. Many of these *Begonias* are flowering beautifully on the rockery, where they have passed the winter without injury. Not many Orchids are flowering now. A few of the more striking are *Cattleya Eldorado* with its rich golden throat, *Oncidium macranthum*, *Dendrobiums albo-sanguineum* and *formosum*, several *Cypripediums*, including the richly spotted *C. Veitchii* (superbians), and the new *Spathoglottis Petri*, recently introduced by Mr. Peter Veitch. The new *Ardisia Olivierii* is flowering in one of the stoves. In foliage and habit of growth it is not unlike an *Allamanda*, and it has large terminal pyramidal heads of pink lilac-tinged small flowers. *Ixoras* are also in beauty—they nearly always are—I. *Fraserii* being noticeable by its fine habit and deep salmon flowers. In one of the trial flower beds a beautiful effect is produced by the new

Wave of Life blue Lobelia mixed with silver tricolor Geranium Mrs. John Clutton. This Lobelia has very large flowers, and will be valuable for large beds; a more compact-growing variety of great merit is Blue Perfection.

SOME of the prettiest FLOWER BEDS that we have seen this year are in Mr. Baring's enjoyable and well-managed garden at Coombe Cottage, and yet they are simple—just the variegated Lady Plymouth Geranium mixed in one case with Crimson King Verbena, and in another with Purple King. These beds afford an agreeable change from the rich masses of scarlet Geraniums. Some other beds are planted with the Oak-leaved scented Pelargoniums and Gnaphalium lanatum, and the silvery sprays of the Gnaphalium peering through the masses of green produce a cool chaste effect, which is much admired. Beds of Clematis Jackmannii are gorgeous, and this and other Clematises with Honeysuckles, Virginian Creepers, &c., growing in wild luxuriance on walls and in festoons, constitute a noteworthy feature of this enjoyable garden. Other features are equally worthy of record, but they cannot be referred to now.

A CORRESPONDENT, "R.," tried the experiment of BOTTLING GREEN PEAS and BEANS in the same manner as fruit by putting them in bottles with cold water and then standing them in a pan of cold water, which was put on the fire until the water boiled, after which they were corked and sealed up when hot. In a few days the corks were blown out. When we tried them last year the bottles exploded. Can any of our readers give any information on preserving these vegetables for winter use?

A MODE of supporting MELONS hanging from a trellis as adopted in the Hon. A. Leslie Melville's garden at Branston Hall is worthy of note. Instead of the fruits being supported by a piece of board or suspended by matting each fruit rests in a small openly-woven yet strong wickerwork basket. The baskets are about 6 inches in diameter, and are of the shape of a large saucer but deeper. They are made at the local basket makers, cost about 3s. a dozen, and last for years. They are suspended to the trellis with string, and have a very neat appearance. On the occasion of a recent garden party held at Branston nothing was more attractive to the visitors—and the garden was extremely gay with flowers—than the fine crop of Melons, each fruit resting in its basket, and producing a somewhat novel yet pleasing effect.

WHEN recently visiting the small but admirably kept garden of J. Swan, Esq., Stonefield, Lincoln, we observed the fine greenhouse roof-covering plant, TACSONIA INSIGNIS, flowering freely. The exuberant growth of this Tacsonia, its fine foliage and pendant crimson flowers, recommend it for covering the roof of a house quickly and ornamentally. T. Van-Volxemi planted in the same house had not grown nearly so freely and had not produced any flowers, both the plants being of the same age. Mr. Brumpton, the gardener, stated that he had tried various plans for inducing T. Van-Volxemi to flower, but without success, while T. insignis flowered freely by simply being planted in the border and having its growths thinly trained near the glass.

A FINE plant of the VARIEGATED AMERICAN ALOE will shortly be in flower at Hampton Court. The plant is on the south terrace, and the flower spike reaches an altitude of about 18 feet, and appears to be little less than 18 inches in circumference at the base. The stem is branching freely, and will produce upwards of a hundred flowers.

IN many gardens we find that VICK'S CRITERION TOMATO is regarded as a valuable acquisition. It produces smooth, highly coloured, crimson fruit in large clusters, and its firmness and flavour render it a great favourite with the kitchen authorities. The plant is a rather strong grower, and requires more room than some other varieties, but when well grown it is undoubtedly one of the most distinct and valuable varieties in cultivation.

A VISITOR to Wimbledon House informs us that the large FIG TREES that Mr. Ollerhead removed from the garden into two of the houses during last winter have proved amongst the greatest successes that must be placed to the credit of that energetic gardener. In the garden the trees were of little value, but in the house they have produced hundreds of fine fruits, which were particularly acceptable for camp parties at Wimbledon during the recent Volunteer contests. Already the trees have produced two fine crops, and other fruits are forming freely. It will be remembered that the trees which were aluded to at the time of their removal were old and of

very large size when lifted, each quite filling a large house 20 to 30 feet long and nearly as wide. They appear to have received no check whatever by removal, and their present condition is altogether satisfactory.

I ADVISE, says "A SPECIALIST," the LIFTING OF ALL POTATOES so soon as the skins are set. Those we have raised are very clean and of excellent floury quality. International Kidney is a wonderful crop. Beauty of Hebron also turns out grandly, those being every way very superior. Rector of Woodstock is difficult to boil; it is so floury. Bountiful is clean and beautiful. Veitch's Ashleaf, Snowflake, Early Vermont, Red Emperor, Model, Bryanstone Kidney, Prince Arthur, and Schoolmaster are heavy in crop and cleaner than we have had Potatoes for some years. Lapstone is not at all up to the mark this year in anything except quality, which is first-rate. Early White Kidney and Early Market have turned out well and are of capital quality. Late kinds are much impeded in growth by the drought, and in some instances are completely at a standstill. It will be no use lifting those, though it would be better to do so in the case of sorts likely to supertuberate, which ruins the crop. The first tubers if lifted before supertuberation takes place will be all right though small and light in crop.

"OUR WOODLAND TREES" is the title of a new work (shortly to be published by Messrs. Sampson Low, Marston, and Co.), from the pen of Mr. Francis George Heath, author of the "Fern World," "The Fern Paradise," &c. The volume, in addition to a descriptive account of British forest trees—illustrated by coloured plates of leaves photographed from nature, and by wood engravings—will include chapters on "The Life of a Tree," "Trees in Towns," "London Trees," Sylvan Streets," &c. "Some Woodland Rambles" with accompaniment of photographs will introduce the reader to some of the most charming scenery of the New Forest. There will further be included in the volume a brief history of the Epping Forest question, whilst also relating to Epping Forest are some descriptive chapters of rambles "Where the Green Leaves Quiver," "Through a Green Ride," and "At Midnight."

It is stated, on the authority of the *Agricultural Gazette* of Hanover, that a discovery has recently been made of a new remedy for the PREVENTION OF RAVAGES TO CABBAGES by the common caterpillar. A steward of an estate in Hanover having observed that one bed of Cabbages was left untouched by caterpillars whilst others were infested with them, found that the healthy bed had a quantity of Dill growing on it, the smell of which, apparently, was obnoxious to the caterpillars. As Dill will grow in almost any soil, it is suggested that the experiment might be tried by agriculturists. As indicative of the possibility of there being some truth in this, *The Colonies and India* says:—"We have heard of the common green ('Gooseberry') caterpillar being kept off by planting Broad Beans close to the bushes; and the Pyrethrum, a strong-smelling weed which is cultivated as a garden border flower, is said to protect Vines from the ravages of the *Phylloxera*."—(*Nature*.)

As showing the great quantities of GARDEN PRODUCE RAISED IN FRANCE, she exported in one year, after supplying her domestic consumption, 3257 tons of Oranges and Lemons, 42,700 tons of fresh fruit, 14,000 tons of dried fruit, 2135 tons of preserves and conserves, 21,300 tons of Nuts, 24,161 tons of dried vegetables, and 173,144 tons (6,414,042 bushels) of Potatoes.

ARAUCARIA CONES.

It appears to me that "W. J. M., *Clonmel's*," Araucaria mentioned on page 91 is the female tree, as I have been assured the form of the cone is globular. We have here one that bears cones freely every year, and is evidently the male or pollen-bearing tree. The form of the cones is something like that of the *Pinus nobilis*, but, instead of standing erect as the cones of that noble Pine, they hang pendant. This season I have sent some of these cones to a gardener that I should think has the female variety, and if so no doubt we shall see the result. I was told by one of our leading nurserymen that it did not mature its seed in this country, but I have also heard that it has. If I hear more about it I will communicate it to you.—T. C.

[The male catkins are ovate-cylindrical, usually growing in clusters of from six to seven at the ends of the branches. The female cones are solitary and erect, they are oblate or nearly globular, and are from 6 to 8 inches in diameter. The tree is

diceious, yet a specimen at Bicton was singular in producing male and female cones on the same branch. Young plants have been raised in both England and Scotland from home-grown seeds.—Eds.]

PLEIONE LAGENARIA.

A CORRESPONDENT, "A. M. B.," sends us a postcard containing the following request:—"What are Indian Crocuses like?" We can best reply by publishing one of the most beautiful of the Pleiones, which has been described as a gem amongst gems. The pseudobulbs are distinct from any other species, being flask-shaped with a peculiar overlapping neck. The flowers are large and solitary; sepals and petals narrow, deep rose colour; lip very large, waved at the margins, white variegated with yellow and rich purple. It flowers profusely during the depth of winter. Native of the Himalayas. The majority of the species grow at elevations of from 6000 to 8000 feet in the forests of Nepal, Sikkim, and Bhotan, and when in flower are said to present a most gorgeous aspect, causing the woods to appear all ablaze. They are mostly grown in pots, but succeed equally well upon blocks; in the latter way they require more sphagnum about them than most

Fig. 16.—Pleione lagenaria.

plants grown in a similar manner. When grown in pots, which is undoubtedly the best method, they should have ample drainage. The soil should be fibrous peat, sphagnum moss, and rich leaf mould in equal parts, adding a small portion of silver sand; but the curious little pseudobulbs should not be elevated above the rim of the pot, as in the usual method of potting Orchids. During the growing season moderate heat and an abundance of moisture are necessary to the development of large strong-flowering pseudobulbs; after these are formed they may be removed to a cool house and kept tolerably dry until the flower buds begin to show themselves at the base of the old bulbs, when additional heat may be applied with advantage.

MARGAM PARK.—No. 1.

THE SEAT OF C. R. M. TALBOT, ESQ., M.P.

ONE of the most charming seats in South Wales, and which deserves to be more widely known than it is, is Margam Park, the chief residence of C. R. M. Talbot, Esq., the senior member for Glamorganshire and Lord Lieutenant of the county, and one of the most extensive landed proprietors in the United Kingdom.

The place itself is old, though the present princely and

elegant mansion is modern; and the grounds, while retaining many of those features which age alone can impart, have at the same time much of the grace and beauty of youth. It would be impossible in a short sketch like the present to do more than touch upon a few of the many features of interest about the place. Unlike nearly all other Welsh parishes the name of Margam is involved in obscurity. It is probably a corruption of Morgan. In very ancient times it went by the name of Pendar—i.e., an eminence covered with Oak trees, and to this day the Oak-clad wood within the grounds is a familiar object to travellers by the Great Western Railway passing along this route. In the olden time Margam was a place of considerable importance, possessing as it did a noble monastery, and lying on the great Roman road which connected Carleon with Carmarthen.

At the dissolution of the lesser monasteries in the reign of Henry VIII. Margam became the property of Sir Rice Mansel by purchase, and it was after this for two hundred years the home of the Mansel family, which removed here from Penrice in about the year 1545. On the death of the last Earl Mansel in 1750 the property came into the possession of Thomas Mansel Talbot, Esq., who afterwards left Margam and lived chiefly at Penrice. The present owner having, however, rebuilt Margam on a new site about forty years ago, it has since been his principal seat.

Margam Park is situated a few miles to the eastward of the pleasant town of Neath, and is about equidistant from the Port Talbot and Pyle stations on the Great Western Railway. The drive from Port Talbot with its copper-smelting chimneys and vapours, and its yellow sand ridges bordering the Bristol Channel at this place, affords but little promise of the grand old demesne in its neighbourhood. Soon, however, the road bends inland, and conducts to a small cluster of houses containing a handsome school house and a small curious-looking octagonal-shaped chapel built by the present Mr. Talbot for the accommodation of the residents about the place. At this point the visitor enters the main approach, which conducts by a slightly ascending gradient through an old Oak plantation to the gardens, pleasure grounds, and mansion. This Oak plantation is a noteworthy feature of the Park, its extent being about 800 acres, while from the altitude to which it is carried it is made to form a background of great beauty and richness to the other attractions of the place.

After a drive of about a mile from the gateway we reach the gardens, over which we are conducted by the genial and highly efficient head gardener, Mr. Muir. The special features of the gardens we reserve for another paper; suffice it to say that after examining them with great interest we are conducted through the orangery adjoining, and the vast and elegant Doric building, specially constructed about ninety years since by the present proprietor's father for the accommodation of the Orange trees in winter, with three graceful fountains in front, the whole forming a feature of much interest and beauty.

We find in the thick clusters of shrubbery which surround the cleanly-kept lawn here many plants of rare excellence. Wellingtonias from 50 to 60 feet high, well furnished from top to bottom; large Sweet Bays, nearly the same size, and almost as much in diameter; the common Portugal Laurel grows to the height of 40 feet; Taxodium sempervirens, 50 feet; Ailantus glandulosa, from 40 to 50 feet; indeed, we never remember having seen better specimens of trees and shrubs of all kinds than are to be found here. We measured one large tree of Platanus orientalis, 70 feet high and 76 yards in circumference, furnished to the ground with branches, and in perfect health. Hydrangeas grow from 8 to 9 feet high, and some of the plants are no less than 18 feet in diameter, and produce from two to three hundred trusses of bloom in the season. A Camellia (Double Red) growing outside is 18 feet high and 20 yards in circumference, and produces hundreds of flowers yearly.

The spaces between the shrubs afford extensive outlooks through the pleasure grounds. The eye is soon attracted, however, by portions of old ecclesiastical ruins in beautiful preservation. There are portions remaining and carefully preserved of the old abbey of Margam, which dates from about the twelfth century. Parts of the walls, containing beautiful specimens of the old windows and pillars, and portions of Gothic arches are scattered over a considerable extent of ground, showing the large space the abbey must have covered in the days of old when the monks inhabited it. Nearly the entire shell of the chapter house still stands, forming one of the most elegant remains in England. It is nearly circular in

form, and about 50 feet in diameter. The windows are fine specimens of pure Gothic. The carved pillars which once supported the roof still stand comparatively little injured, but the roof itself has fallen in. A number of crosses and mural tablets, which are supposed to have originally recorded the names and qualities of deceased abbots or other dignitaries, now rest against the wall. The carvings and inscriptions on them are almost completely obliterated. Much labour has been judiciously expended in restoring portions of the old walls and preserving them from further decay; and well deserving are they of such care, for it is rare that ruins are to be found amid surroundings that lend to them such grace and charms. The parish church, which stands in close contiguity to the old abbey, originally formed a part of its nave. It is a good specimen of old Norman architecture. The west front and massive pillars are twelfth-century work, built of stone brought from a quarry near St. Donat's, upon which age and weather

seem to have little effect. In the church stand some very handsome tombs with recumbent figures, in memory of the Mansel family. It was rescued from decay by the present Mr. Talbot's father, and is now regularly used for public worship. It appeals strongly to one's sense of the beautiful to stand at a little distance and view the ruins of the abbey with the Orange house and church in the front, relieved against a pyramidal-shaped hill of about 600 or 700 feet in height, clothed to the very summit with the sober-tinted foliage of the thickly clustered Oak trees.

Turning to the right a view of a different but not less exquisite kind of beauty meets the eye. At the further end of a vista amongst the lovely trees is seen the noble and graceful end of the mansion, with its lofty tower standing in sharp relief against the sky. The approach to it is up an inclined plane, broken here and there by flights of steps extending the whole width of the roadway, some 30 feet. We have rarely

Fig. 17.—MARGAM PARK.

seen a more charming architectural object than the view of the house as seen from this point. Ascending the approach we find that the house is of grand as well as of elegant proportions. Its site has been skilfully chosen on a plateau between the hills above and the lower grounds where the gardens and orangery are situated. It would be difficult to conceive a more beautiful situation, sheltered as it is by the well-wooded hills which lie behind it from the northerly and easterly winds; while to the south and west are far-reaching views, embracing a picturesque stretch of Glamorganshire in the foreground, with the wide expanse of the Bristol Channel behind, and the hills of Somerset and Devon in the distance closing-in the prospect.

A small but tastefully laid-out geometrical flower garden occupies a portion of the plateau on which the house stands. It is bedded-out in the usual way with Geraniums, Calceolarias, Verbenas, Coleuses, dwarf Candytufts, Mesembryanthemum cordifolium variegatum, Violas of different colours, and other plants all neatly arranged in the different beds, which for individual and general effect it would be difficult to surpass. The building was, as we have stated, designed by Mr. Talbot the present proprietor, and erected under his superintendence about forty years ago. We do not pretend to furnish an architectural description of it, but the engraving which accompanies

this notice will convey better than words a conception of its elegant proportions. We should estimate the height of the tower at about 100 feet. The view from the summit of it on the hill, or sheltered side, reminds us of that from Drummond Castle in Perthshire; but the far-reaching panorama on the lower side supplies a variety and interest that are wanting in that celebrated highland castle. It would be an intrusion on privacy to seek to carry the reader through the interior of this fine mansion. Suffice it to say that the Gothic entrance hall and staircase we have not seen excelled in domestic architecture, while the treasures of art which the rooms contain, and the style in which they are furnished and ornamented, bespeak limitless wealth expended under the guidance of refined artistic taste.

It may not be inappropriate to finish our present sketch by stating that Mr. Talbot, the proprietor, is the father of the House of Commons, having represented Glamorganshire for the long period of forty-nine years. He has been several times opposed, but never defeated. He was in parliament when the present premier was struggling into fame as a novelist and long before he had entered the arena of politics, and also before the present Queen was crowned. He has been twice offered a peerage, but declined it. He received much sympathy two years ago on the occasion of the death of his only son at

the age of thirty-three years. Mr. Talbot has three daughters, the second of whom is married to J. Fletcher, Esq., of Salton Hall near Edinburgh.—A. PETTIGREW, *Castle Gardens, Cardiff*.

DISBUDDING ROSES.

IN the *Journal of Horticulture* you most kindly admit letters upon all subjects. As an old Rose-grower I am, of course, most interested in those that are written on the subject of the queen of flowers. Everyone has, of course, a right to his own opinion—*chacun à son goût*; but I hope that it will not be thought very presumptuous in a poor old fogey if he takes the liberty of disagreeing with your correspondent "A. C." on the subject of disbudding Roses. He states in his letter, published by you August 1st, that "Since the Rose show month my Roses have been doing exactly as they like." So have mine, and a jolly time they seem to have had of it. I do not like only to write what my experience of letting my beauties alone is, but beg to enclose you, for the advantage of your numerous visitors, two trusses that I cut off one plant of Mrs. C. Wood (one has eighteen, the other twenty-one buds), also a single truss of La France with twenty-nine buds. I send them as samples of what a Rose show might be if carried on under the suggestion of "A. C."

Though very near the threescore years and ten I still look with much pleasure on the lovely forms around me, and confess that the Lesbias of the present day are, perhaps, sometimes a little tightly laced, but I think that the Norah fashion (of course I only compare them in the way of Roses) gives rather a confused idea (*vide* trusses sent), of what beauty is; but if the world at large would consent to an exhibition of Lesbias and Norahs I would willingly agree, if considered competent, to be one of the judges, and a friend of mine who is reading this over my shoulder says he will also be a judge, and if we do not agree can call in some other old woman to give her casting vote.—AN OLD ROSE-GROWER, T. F.

NOR too frequently nor too plainly has "A. C." denounced the plan of disbudding Roses that is now so common. To produce the grand blooms that win cups at exhibitions disbudding is imperative, as the prizes are awarded to the most perfect individual blooms that can be produced, and not to "trusses," as the blooms are anomalously and officially described in the schedules.

It is rare indeed to see a naturally grown and beautiful truss of Roses at a Rose show. Grandeur of isolated blooms prevails there, but it is a formal artificial kind of beauty that does not display the Rose in its natural state of loveliness. The present system of Rose exhibiting must continue, no other plan can supersede it; but it would be just as well to call the blooms by their right names. Yet, as so timely suggested by "A. C.," cannot supplementary classes be made for exhibiting Roses in trusses—that is, a stem containing as many blooms and buds as the exhibitor chooses to stage? Boxes thus filled would afford a delightful change from the present monotonous—grandly monotonous if you like, but still monotonous—aspect of Rose shows; and the trusses, real trusses, would afford by far more truthful and correct ideas being formed of the several varieties than does the present system of exhibiting only highly fed and isolated blooms.

In regard to Roses and Rose-showing it is well to bear in mind that by far the greater number of visitors who are admirers and growers of the flower are those who wish to see the varieties exhibited so as to show their natural characters. Not one grower of Roses in ten grows them on the disbudding system so as to produce a few grand blooms for exhibition, but they grow them for producing trusses for beautifying their gardens and adorning their homes.

The two systems referred to are essentially distinct, and the blooms produced by one mode and the trusses by the other cannot compete in the same class. Let blooms be called blooms and trusses trusses, and let classes be formed accordingly, and Rose shows will be more varied, interesting, and instructive.—OCCASIONAL EXHIBITOR.

THE FLORA OF CYPRUS.

SPEAKING of the flora of Cyprus Drs. Unger and Kotschy, in their work "Die Insel Cypern," say:—

"In Cyprus prairie or meadow land does not exist; the 'Ackerland' takes the place of it. After the rains, but only for a short time, cereals give a satin-like green to the land-

scape; and among them grow a profusion of flowers; but these artificial rather than natural fields fade more quickly than the flowers, and scarcely last a few weeks beyond the last spring rain. There is only one small corner of the island where the vegetation resembles ours. The great heat of the summer destroys all the tender plants; only those plants survive which, through their anatomical construction or hard substance, or in consequence of growing near water, can resist the effects of the heat.

"There is great resemblance in the vegetation throughout the island to the Mediterranean. In February and March there is on all the river edges a profusion of Lilies; in April and May on the land side is one carpet of flowers. During the heat, however, the land assumes a yellow tint. Pine forests abound, Olives, Myrtles, and Laurel trees. As far as the island has as yet been explored we know that there are a thousand different sorts of plants. No eastern island can show such a rich forest growth as Cyprus.

"The *Pinus maritima* in Cyprus covers the hills and mountain regions to the height of 4000 feet as one of the commonest trees. The *Pinus Laricio*, which covers all the heights to 4000 feet above the sea, rises on the western mountains of the island to 6000 feet, and gives it a dark appearance from the sea. The wild Cypress (*Cupressus horizontalis*) is the third tree which grows commonly in the eastern part of the island and in some places forms by itself entire woods. On the whole of the northern chain of mountains this wild Cypress grows often to the height of from 2000 to 3000 feet above the sea. Great forests of wild Cypresses must also have covered the whole of the south of the island, as also a shrub, the *Juniperus phœnicea*. In the north several varieties of Oak are found, and throughout the island the *Arbutus* abounds; the Carob tree and Olive flourish on the banks of all the rivers and up to an elevation of 1000 feet above the sea."

HAMPTON COURT GARDENS.

THE floral embellishments of the public parks in the vicinity of the metropolis constitute an important feature of their attractions. Artistic merit of the highest order is exemplified in those parks, and skill both in the culture and arrangement of plants and flowers is strikingly displayed by the several managers.

Although situated at some distance from the metropolis, yet Hampton Court may be said to belong to the Londoners; it really belongs to all, for the palace and gardens are free to all comers on six days out of the seven. The gardens indeed are open on seven days, but the State apartments are closed on Fridays, a fact that visitors occasionally overlook and consequently experience some disappointment when they arrive at this celebrated place of public resort on that "unlucky day." Such disappointment, however, as that experienced by some visitors on Friday last is, it is hoped, not common. A gentleman from Australia had been hoping to see the State rooms all his life and that day afforded him the only opportunity for doing so, as he had to sail the next day for the Antipodes. But the rule was inexorable; the apartments were "closed for cleaning," and the journey of sixteen thousand miles ended by an outside view. The visitor bore his disappointment philosophically and did not fall into the vulgar error of abusing the porter. It was slightly different with an American visitor who was placed in the same predicament, and who with characteristic cuteness "guessed his house was cleaned every morning slick, and was always ready for visitors, and guessed if that house was in his country it would be ready too." It is well, therefore, that gardeners and others whose primary mission is to inspect the grounds and flowers should not deprive themselves of a rich supplementary treat by committing the same error of selecting Friday for a visit. Yet while visitors arrive from all countries, it is naturally the Londoners who are represented in the greatest numbers, the attendance last year numbering upwards of 200,000.

Although somewhat early in the season the flower beds are about in full beauty. The plants were good to begin with, were planted closely, and have grown freely: hence their present satisfactory condition. The aspect of the grounds from the west front of the palace is one of unmistakeable grandeur. The three splendid avenues of Elms converging to the centre of the terrace; the fountain in the centre in its basin 130 yards in circumference and its 120 jets; the smooth expanse of lawn with lines of venerable Yews and Hollies, some of them enshrouded in Ivy; and the large, numerous, and

excellently filled flower beds, produce a picture of art and nature balanced and blended in a manner that commands general admiration. The general view is admirable, and a closer inspection of the flower beds proves that they are admirable too. Flowers old and new are provided, and arrangements old and new are represented. It will be fashionable to look at the new flowers first, and these are

DR. DENNY'S GERANIUMS.—A considerable number of the new varieties of that celebrated raiser are bedded out, the plants having been supplied by Messrs. James Veitch & Sons. They are in round beds, but as the plants had been cut rather severely for cuttings they were not seen in their most favourable aspect. The following are the varieties represented:—

Cleopatra.—A distinct and novel colour (carmine magenta), and a remarkably fine and well-formed flower; a tolerably free bloomer, but not particularly effective from a distance; the habit of growth, too, is a little irregular. Better for pots than for beds.

Amazon.—A grand rich scarlet suffused with crimson; flowers large, of great smoothness and substance, and freely produced. A strong grower, and fine for large beds and for pots.

Heather Bell.—A distinct and lovely colour, bluish pink; flowers of the finest form and of great substance of petal. One of the best for pots, but not a good bedder.

Nyanza.—Scarlet, a rich glowing mass. A variety of great merit for pots, and promising as a bedder.

Atlanta.—A distinct and novel colour, purplish crimson; a fine flower, but the plant rather too strong in growth for ordinary bedding purposes.

Globosa Major.—Semi-nosegay, crimson, fine bold trusses, but growth of plant rather unlevel. Requires a large bed to show it to advantage.

The above have separate small beds, but the following are selected from several varieties planted in rows in a large bed:—*Gnome*, glowing scarlet, dwarf and free; one of the best of all for small beds. *Isis*, brilliant scarlet; a stronger grower, and would probably show to advantage in a large bed. *Zuleika*, a rich and distinct colour; finer for pots than for beds. *Irene*, purplish crimson, with a rich orange-rayed blotch on upper petals; it is dwarf and free, but forms seed pods too freely for a bedder; fine for pots. As seen at Hampton Court under disadvantageous circumstances, and possibly grown from spring-struck cuttings, the varieties, with one or two exceptions, do not afford evidence of being superior bedders. As an on-looker remarked, "They are too good for beds and must be grown in pots." They are generally too robust in habit, and do not possess sufficiently dark green foliage to render them effective for outdoor display.

Some other beds—large oblongs alternating with the circles—are extremely fine. The most pleasing are perhaps those where the central mass consists of two distinct colours. For instance, *Geranium Bijou* carpeted with *Viola Blue Perfection*, broadly banded with *Iresine Linden* and edged with *Golden Stellaria*, is a charming combination and worthy of imitation. *Viola The Tory* intermixed with variegated *Geraniums*, and the same *Viola* with *Centaurea candidissima*, produce a pleasing effect. Particularly attractive are the *Centaurea* and *Verbena venosa* in mixture, and *Abutilon Thompsonii* variegatum carpeted with blue *Violas*. *Pelargoniums Mrs. Pollock* and *Sophia Dumaresque* carpeted with blue *Lobelia* produce a cheerful and lively effect, and so also do other combinations of the same nature. This mode of planting the beds is admirably adapted for producing fine floral masses in early summer. The beds probably show to advantage on account of their size, many of them being 40 feet long and 12 wide. Several beds about 12 feet square are simply but effectively filled, such as *Geranium Amaranth*, which is splendid, edged with *Geranium Manglesii*, and the same *Geranium* banded with *Bijou* and blue *Violas*, and edged with *Iresine Linden* and *Königa variegata*; also *Ageratum Imperial Dwarf* broadly banded with *Geranium Manglesii*. A bed of *Geranium Happy Thought*, broadly banded with *Geranium Golden Harry Hiever*, is very novel and good. Many other beds are effective, but it is not necessary to particularise them. *Calceolaria Prince of Orange* is literally a "dead failure," for most of the plants are actually dead—the one failure in a fine flower garden. The best beds of scarlet *Geraniums* are those of *Vesuvius*, closely followed, however, by *George Natchett*. The best crimson is *Waltham Seedling*. By far the best pink is *Amaranth*, but a bed of *Mrs. Haliburton* is very promising. This variety is deeper in colour than *Christine* which it resembles in habit of growth.

Carpet bedding is also excellently represented, the designs

being of a free pleasing character, and planted with much taste. Cheerful colours and neutral tints are well balanced and the beds are decidedly good; a few of them perhaps have seldom been surpassed in this particular style of garden decoration.

Other features of Hampton Court merit attention: the old Dutch garden with its Yews and hardy flowers; the Agaves and Oranges on the terrace, probably centenarians (one of the Aloes will shortly be in flower), a wonderfully fine example of the *Wistaria sinensis*, and the grand old Vine, which is this year carrying 1200 bunches, small but very regular, the foliage being healthy and clean. All these are points worthy the inspection of the visitor, who when he has examined them will say that the gardens at Hampton Court are highly deserving of patronage, and that their condition reflects much credit on Mr. Graham, the Superintendent.

THE OLD MARKET GARDENS AND NURSERIES OF LONDON.—No. 21.

"BROMPTON," observes Mr. Brewer, writing concerning the place fifty years ago, "has lately experienced a considerable increase of buildings, and is now nominally divided into two parts, termed Old and New Brompton. The latter division of the hamlet chiefly consists of rows of houses, which are of a crowded but usually respectable character. Old Brompton still retains a similitude of rural aspect, and is yet celebrated for well cultivated nursery and garden grounds." Since the "Great Exhibition year" Brompton has undergone an "increase of buildings" which throws the Georgian increase into the shade, and if it has a "similitude of rural aspect," this has now become very shadowy indeed. The nurseries have undergone rapid diminution. The market gardens probably do not cover more than a third of the space they occupied at the beginning of this century. The outlying districts belonging to Fulham and Hammersmith may, however, give us some imperfect idea of what Brompton was in the olden time; now a part of it is called South Kensington, not without a tinge of absurdity, the name pretty nearly representing New Brompton, but not quite with exactness. A portion of Old Brompton was known formerly by the rather absurd name of "Little Chelsea," so that the past generation can hardly afford to laugh at the present one; it was along the line of the Fulham Road, just beyond Brompton Heath and Chelsea Park, but formed no part, as I understand, of Chelsea parish. The etymologists, it appears, have not exercised their ingenuity in discovering or inventing an explanation of the word "Brompton;" of course the final "ton" represents "town," as in many names of places. I would suggest it may have been designated from some owner of the land, or possibly it was originally "Broom town," from the Broom which once flourished in the open ground, such as Brompton Heath. And the by-passer along the Fulham Road may survey with interest the condition of a part of this heath (so-called) not yet built upon, but which was cleared for that purpose many years ago—it must be nearly twenty I think. Before that the land was in the hands of market gardeners. Though lines of road were traced out and cellars built matters went no farther from some cause, and now there grows a curious commingling of plants and shrubs on this neglected property, and amongst these may be noticed specimens of the Broom, the seeds of which had probably laid dormant in the earth.

An excuse for the application of the name "South Kensington" to northern districts of Brompton lies in the fact that these belong to the parish of St. Mary Abbott, Kensington; but though we commonly speak of the gardens of the Royal Horticultural Society as situate in Kensington, I fancy they might have been claimed for Brompton, certainly they occupy some of the land that belonged to the renowned Brompton Park Nursery; and, before speaking of that historic and extensive establishment, it should be noted that the Society (destined, I trust, to retain its Kensington property for a long time to come) before the Chiswick Gardens were planned had a small space at Kensington, on which experimental culture was carried on, chiefly in the open air it seems. This was commenced early in 1818, but closed in a few years; it was situate to the west of Earl's Court Road, not far from Edwades Square. It was only open to visitors from two o'clock to six.

A number of authors, in describing Brompton Park Nursery, have referred to this establishment as if it was solely entitled to the name of Brompton Park. Though the greater portion of the park was absorbed into the nursery at first (to undergo

various reductions as time went on) there was a residence Park House, near Prince's Gate, only removed in 1856, to which was attached a small section of the domain. In an ancient house on this estate was born Philip Percival in 1603, the friend of John Pym; and the Percivals owned Brompton Park till near the end of the reign of Charles II. Originally containing possibly 100 acres, it was divided, and the larger half, about 67 acres, was formed into a nursery garden in 1680 or 81 by a firm styling itself Lukar, Field, Cooke, & London. Lukar was gardener to the Queen Dowager at Somerset House in the Strand; Field held a similar situation with the Earl of Bedford at Bedford House, also in the Strand; Cooke was gardener to the Earl of Essex at Cashibury; and London* to Bishop Compton at Fulham. As the first establishment of any pretensions, if not actually the first London nursery, much interest centred in it, and it was frequently visited by gardeners as well as botanists. The two senior partners died about 1686, and in 1689 Cooke disposed of his share to Henry Wise, and the firm became London & Wise. Wise had chiefly to do with the laying-out of Hampton Court, and the partners were employed in the planting of Kensington Gardens. During the winter for some years it was usual to remove choice plants from Kensington Palace to their nursery. A literary fruit of their association was an English version of a French book, "The Complete Gardener," which Messrs. London & Wise published in 1701.

The learned and somewhat prosy author of "Sylvia," John Evelyn—who did, however, undoubtedly feel a genuine satisfaction in all that tended to promote the advancement of botanical science—displays unwonted enthusiasm in his description of Brompton Park Nursery. One sentence of his, in reference to a visit he made to the establishment, I must quote, as a curious specimen of intricate English. His style is very different from the curt expressive manner that another noted man of that day, Samuel Pepys, adopted in putting down his jottings. He observes:—"Of all I have hitherto seen, either at home or abroad, or found by reading many books published on the subject, pretending to speak of nurseries and plantations for store and variety, directions for the designing as they term it, the skilful making, plotting, laying-out, and disposing of a ground to the best advantage—in a word, for whatever were desirable for the furniture of such a ground with the most excellent and warrantable fruit, I say warrantable because it is peculiarly due to their honest industry and so rarely to be met with elsewhere, and other accessories to gardens of all denominations as in that vast ample collection which I have lately seen and well considered at Brompton Park." Then he proceeds still further to commend Messrs. London & Wise, who in reading their eulogium must surely have been amused at the confused sentence by which it was introduced; and he further adds that "they have a large and noble assembly of the flowering and other trees, perennial and variegated evergreens and shrubs fittest for our climate, and understand what best to plant the humbler bosage, wilderness, or taller groves with—for which purpose, and for walks or avenues, they have store of Elms, Limes, Platans, Constantinople Chestnuts, and Black Cherry trees!" Then in a bit of slang, which he had picked up in his studies of French books, Evelyn further praises these gardeners for their management of the "potagere, meloniere, and culinarie" domain. The fame of the nursery steadily increased, for Bowack, writing of it in 1705, remarks that the proprietors sent plants and trees to noblemen and gentlemen in every part of England. "It has been affirmed," says he, "that if the plants in it were valued at but 1*d.* a piece they would amount to above £40,000." As £1 contains 240 pennies the sum here stated would represent nearly ten millions of plants, evidencing the romantic character of the estimate. The plants, moreover, might well have been taken at a higher sum at a rough guess—say even 1*s.* each, excluding seedlings. Apart from such conjectures there is abundant evidence of the large business carried on by this establishment both in the eighteenth and in the first half of the nineteenth century. This was not confined to Britain, for many plants were sent to the Continent from Brompton Park; but as London grew other nurseries sprang up, and to some extent affected the older nursery, which was, owing to the number of persons it employed, not merely a plant nursery—it was also a training place for gardeners. An injurious influence was exercised upon some of the plants by the growth of the metropolis, but the land attached to the nursery did not undergo great diminu-

tion until after the reign of George III., for according to Faulkner, when he wrote in 1820, Brompton Park Nursery contained 56 acres, at which it remained at the period when this and adjacent properties were purchased by the Commissioners of the Exhibition of 1851.—C.

TREE-PLANTING IN WASHINGTON.

In the *American Agriculturist* Mr. Peter Henderson pays a merited tribute to the skill, taste, and judgment of Messrs. William Saunders of the Experimental Garden of the Department of Agriculture, William R. Smith of the Botanic Gardens, and John Saul, the nurseryman and florist, who compose the "Parking Commission," and whose work in planting the fine avenues and streets of the City of Washington with handsome and appropriate trees has produced, as he says, results that probably no other city can equal.

Already 40,000 trees have been planted, some thirty kinds being used, the bulk, however, being of ten kinds. These, named in the order they are valued by the Commission, are the following:—Silver or White Maple (*Acer dasycarpum*), then American Linden (*Tilia americana*), American Elm (*Ulmus americana*), Scarlet Maple (*Acer rubrum*), Box Elder (*Negundo aceroides*), Sugar Maple (*Acer saccharinum*), American White Ash (*Fraxinus americana*), English Sycamore (*Acer Pseudo-Platanus*), English Button Ball (*Platanus occidentalis*), Tulip Tree (*Liriodendron tulipifera*), Honey Locust (*Gleditsia triacanthos*), and Norway Maple (*Acer platanoides*).

These and the other sorts are set 20 to 25 feet apart, and there are miles and miles of streets in which not one dead or diseased tree can be seen, which shows that the planting must have been done in the best possible manner. The trees were transplanted as the first necessity; and the Commissioners, frequently receiving from distant parts trees which were not in a satisfactory condition as to their roots, planted them out in their own grounds one season before risking them in the streets.

The trees when planted averaged 1½ inch in diameter and 12 feet in height. The hole for the roots is dug about 5 feet across and 2 feet deep. When the natural soil is unsuitable good soil is brought from elsewhere. Every tree when planted is surrounded by a plain but substantial sparred tree guard 6 feet high, which serves the double purpose of protecting the tree from injury by cattle, &c., and of shading the stem from the sun—an important precaution, since trees grown in masses, either in nursery or forest, shade each other and suffer greatly when removed and exposed singly to the blazing sun. The great success in planting the avenues at Washington is no doubt due to the persistent use of this precaution, which is never omitted.

When this work, which has been going on for five years, is complete, one may then drive for two hundred miles through the broad and ample shaded avenues of the American capital, and imagine they are passing along the rides of a great park. —(*Journal of Forestry*.)

WORK FOR THE WEEK.

KITCHEN GARDEN.

Sow the principal crop of Tripoli Onions and Winter Spinach, sowing the latter in rows 15 inches to 18 inches apart, and about an inch deep. Cabbage for the main crop ought to be sown. Enfield Market, Hill's Dwarf Incomparable, Nonpareil Improved, Wheeler's Imperial, Heartwell Early Marrow, and Battersea or Fulham, are all excellent; for small gardens, or for taking up little space, Little Pixie and Atkins' Matchless are of superior quality, and may be planted a foot apart. Red Dutch is the best sort for pickling. A sowing of Lettuce should be made for winter or early spring use. The best sorts for this sowing are Early Paris Market for lifting into frames in autumn; Hicks's Hardy White and Brown or Black-seeded Bath Cos; Stanstead Park and Lee's Immense Hardy Green in Cabbage varieties. Make a last sowing of Turnips, White Stone or Six-weeks, Golden Ball, and Chirk Castle Black Stone, are all good keepers and of excellent quality. Continue sowing Radishes as required, and the sorts for winter use—viz., Black Spanish, China Rose, and Californian Mammoth; they must be afforded rich light soil and an open situation. Carrots sown at this time are often useful in spring. Select Early Nantes, which is excellent, and James's Intermediate Scarlet for this sowing; sowing the first in drills about 6 inches apart, and the last 10 inches, choosing a sheltered situation and soil of a friable nature, affording a liberal dressing of soot or wood ashes with a view to check wireworms and grubs.

Complete as soon as possible the planting of Broccoli and Greens of every description for spring use, also Cauliflower and

* A full account of the life of this remarkable man will be found in vol. xx., page 196.

Cape Broccoli for autumn or early winter supply. Early-sown Cabbage prick off so soon as the plants are large enough in order to keep them sturdy and to enable them to better withstand cold. Attend to earthing early Celery and to watering the later crops liberally. Plants may yet be planted for a late spring supply. The trenches need not be deep now, well-drained light soil being made choice of, and a sheltered situation. Incomparable (Sandringham) Dwarf White and Williams's Matchless Red are hardy and remain a long time fit for use. Any late plants required for using green after the blanched supply is exhausted may be planted in beds 4 feet wide, placing the plants 9 inches apart in rows a foot asunder crosswise of the beds.

If a very late crop of Peas be wanted seed should now be sown in a pit in rows 2 to 2 feet 6 inches apart, affording them from 10 to 12 inches depth of moderately rich light soil, and a distance from the glass for such kinds as Little Gem and Blue Peter of about 2 feet; but Unique, which is a fine Pea for this purpose, should have more head room, or eight or nine peas may be sown in 10-inch pots and then placed in a warm situation outdoors, removing them to a light airy house in October, or before frosts occur likely to injure them. A pit should be sown at once with French Beans for a late supply, and it must be heated so as to maintain a night temperature of 55°, and 65° by day when required, but the lights need not be employed until the weather becomes cold in September. Negro Long-podded is excellent for this sowing, also Osborn's Forcing.

HARDY FRUIT GARDEN.

Wasp nests are numerous and should be destroyed. We make a squib by moistening gunpowder with water, adding about a fourth of flowers of sulphur to the powder, and forming the mixture into a paste, wrapping it in brown paper, tying one end up, and drying so as to have the squibs in the right condition for burning slowly. After dark, the nest being marked during the day, one of the squibs is lighted and pushed well into the hole. A sod is placed over it and rammed down so as to confine the fumes, and about a minute after the squib is spent the nest is dug out and the grubs crushed with the back of the spade, filling up the hole, and the work is done. If the nest is suspended tie the squib on a stick, light and apply to the entrance, holding it there steadily. The fumes will kill every wasp, and all that is wanted further is to take down the nest and bury it. Most under gardeners like this sort of work; there is danger of being stung by stragglers, which makes the work enticing. The squibs require to be about half an inch in diameter and 3 inches long. It is an old system and better than many new notions for destroying wasps.

Mildew, owing to the dry weather, appears upon the fruit of Vines against walls, and should be met by dusting with flowers of sulphur. All laterals should be closely stopped or removed, as well as superfluous shoots, so as to admit light and air to the fruit, which should be gone over to see that there has been no neglect in thinning the berries, for they do not attain so good a size nor ripen so well as when they are thinned just sufficiently to prevent the berries wedging.

Plums on trained trees against walls are swelling off well. Keep the leading shoots closely nailed or tied-in, pinching back superfluous shoots to one or two leaves, and remove or stop forerights; if the shoots have not previously been stopped, stop them at the third leaf. Pyramid trees of Plums have cast most of the fruit. Rivers's Early Prolific is now ripe, and valuable it is on account of its earliness. Red spider is in many instances infesting fruit trees trained to walls, particularly the Peach and Nectarine, probably owing to the hot weather and the dryness of the borders. Give the roots a thorough watering, and when the trees are carrying a heavy crop afford them liquid manure to assist in swelling off the fruit and to help the plumping of the buds for future bearing. Syringe well in the evening, but not after the fruit commences ripening. Lay-in the young wood as it advances in growth, and secure the extensions by nailing or tying, keeping the shoots rather thin so as to secure the benefit of sun and air to ripen them. Any leaves overhanging the fruit may be shortened or drawn aside, but leave at least a portion of the leaf to mature the bud or buds at its base. In gathering the fruit of Apricots, Peaches, and Nectarines great care must be exercised, as the tender tissue is soon injured by pressure or the least fall, and when either occurs decay soon sets in, whereas if it is handled carefully and laid on padded shelves in a well-ventilated fruit room it will keep several days, manifestly improving the quality, as it is hardly possible to gather fruit from trees of sufficient ripeness for table without great risk of its receiving injury in handling.

A few bushes of Gooseberries should be closely netted to exclude small birds, and if need be wasps, by hexagon netting, which is far preferable to mats, which should never be used unless the after consequences are unimportant. Red Warrington is one of the best Gooseberries for late use; but some of the Lancashire kinds are good for this purpose, such as in Reds—Echo, Overall, and Top Sawyer; Whites—White Lion, Wandering Girl, and Tallyho; Greens—Thumper, Jolly Cutler, and Profit; Yellows—Husbandman, Teazer, and Viper: nor must Red and White Currants be neglected covering-up to preserve the fruit until a late

period. Morello Cherries must have thorough protection from birds, or hexagon netting if wasps are voracious. Continue to plant out Strawberries as the ground becomes vacant and the runners well rooted, which has been somewhat retarded by the late droughty weather. Those already planted and growing away freely will put out runners, which must be removed as they appear, and the ground kept free of weeds by hoeing as required.

FRUIT HOUSES.

Vines.—Muscats and Lady Downe's cannot stand the direct rays of the sun through large panes of glass; but there is this difference—Muscats must have plenty of light to put on the golden colour that denotes high finish, Lady Downe's finishing well under a canopy of foliage; indeed black Grapes colour in proportion to the ample foliage, and white Grapes appear to require more light and the shoots thinner. A night temperature of 70° should be maintained with a chink of air on at the upper part of the house, and very free ventilation by day until all danger from scalding is past; and when colouring commences (as it ought by this time if the late kinds are expected to keep fresh and plump through the winter) have fire heat to insure a minimum temperature of 70°, and maximum by sun of 85°, with moderate ventilation night and day in dull weather, proportionately increased in bright days. The roots must not be neglected for water; but if they have been too dry during the swelling period Vines carrying heavy crops will afford a plentiful harvest of shanked berries. See that the laterals are kept well stopped, and everything likely to contribute to good finish attended to promptly. Late Vines in some localities were badly ripened last year both in fruit and wood; and unless well attended to with water at the roots both inside and outside the house, and carefully fired through this season of successive dull weather and scorching days, may if kept close show indications of mildew, which should be met by painting the pipes with sulphur, putting on brisker fires, maintaining a rather higher temperature with liberal ventilation. Red spider must be kept under by similarly painting the pipes, but the temperature need not be raised nor freer ventilation be given for it. Let the border inside and outside have a good soaking with water at 90° if at all dry, for the roots will require to send up a supply of nutriment in quantity for some time yet, and a healthy growing state of the soil does not retard but assist in the perfecting of the crop, insuring well-swelled berries and high finish.

Peaches and Nectarines.—As the trees in the succession houses become freed of the fruit all the bearing wood of this season should be cut out unless forming part of the extensions, and the shoots where too thick should be thinned out to admit light and air to help to ripen the wood, afterwards giving the trees a thorough washing with the garden engine. See that the borders inside and outside do not want for water, especially in the case of late houses where the trees are now swelling off the fruit, such trees being assisted by liquid manure and mulching the surface with short manure. Continue the syringing morning and evening until the fruit is well advanced for ripening, admitting air freely, in fact full ventilation day and night except in the case of high winds and an unusual low temperature at night. Peach scale attacks the trees sometimes when the fruit is advanced for ripening or just afterwards. If prior to ripening, we do not advise any measures to be taken against it other than picking and sponging; but immediately the fruit is gathered syringe the trees thoroughly with paraffin a wineglassful to four gallons of water, mixing thoroughly with the water and keeping mixed by alternate squirts of the syringe into the watering pot and trees. If this be not done it is better left alone, as some parts of the trees will be smeared with paraffin purely and other parts with water only, doing more harm than good, whereas properly used it destroys the scale and does not in the least injure the trees. It is also effectual against thrips and red spider, indeed every kind of insect. In the earliest forced house some of the leaves will be beginning to change and drop off, in which case the lights if removed may be put on, but admitting all the ventilation practical, as if heavy rains set in some of the buds may start into growth, but by putting on the lights the inside borders will be kept drier.

PLANT HOUSES.

Greenhouse.—Young Fuchsias are every way better than old plants. Cuttings should now be taken of free-growing shoots (blooming shoots though they strike freely never make good plants), they strike freely in a cold frame kept close and moist, shaded from bright sun. When rooted pot off singly in small pots (3 or 4 inches), and keep them near the glass in a genial temperature, shifting them into 6-inch pots about six weeks afterwards. They do well in turfy loam, and a fifth part each of well-decayed manure and leaf soil and a sixth of sand. Any plants of these that flowered early will, if now cut-in slightly and thoroughly washed with a solution of soft soap, 2 ozs. to the gallon, to cleanse them from thrips and red spider, removing an inch or so of the surface soil, replacing with fresh and rich, placing them in a rather close house or pit and syringing freely, they will break freely and show flower plentifully, coming in towards the close of September, and with a temperature of about 50° from artificial means will continue for a long time if assisted with weak liquid manure. They are very valuable for cutting from.

Pelargoniums.—Early-flowered plants of the Show, Spotted, Regal, and Fancy kinds will be ready to be cut down, the soil being moderately dry, otherwise the roots will suffer. Old plants should be cut back to two or at most three eyes, young plants to three or four. Place them in a cold pit or frame, tilting the lights to admit plenty of air, and in fine weather they may remain off, but over the plants tilted during rain. In bright weather syringe lightly every afternoon, giving no more water than to keep moist. Zonals showing signs of exhaustion feed with liquid manure, and they will bloom until late in autumn.

Azaleas if placed out of doors must be stood upon a bed of ashes or other bottom impervious to worms, and the plants during heavy rains be placed on their sides, or, what is better, erect a wood framework over the plants to carry a roller and canvas covering to let down during very bright weather for two or three hours after placing outside for about a week, and during heavy rains, but do not allow it to remain over the plants longer than is absolutely necessary. The pots must be protected by canvas from the powerful rays of the sun, or they will be so heated as to destroy the roots.

Kalosanthes.—Cuttings may now be struck, taking cuttings of about 6 inches in length, stripping off the leaves one-third their length, and inserting singly in small pots in a cold frame fully exposed to sun, where they will soon root. *Vallota purpurea* should have a light airy situation, and manure water after the scapes appear and until the flowers expand.

TO CORRESPONDENTS.

* * All correspondence should be directed either to "The Editors," or to "The Publisher." Letters addressed to Mr. Johnson or Dr. Hogg often remain unopened unavoidably. We request that no one will write privately to any of our correspondents, as doing so subjects them to unjustifiable trouble and expense.

GLASTONBURY THORN.—"Ebba" wishes to know where he can obtain the Glastonbury Thorn and the green-flowered China Rose.

LABOUR REQUIRED FOR GARDEN (*An Irish Subscriber*).—Three men with a working gardener would be sufficient to keep what you name in good order and high cultivation.

GAS-HEATED BOILERS (*T. K.*).—We have heard that they are sufficient to exclude frost from small greenhouses.

PARSLEY COLOURED (*E. B.*).—We think the pink tinge ornamental, and should not try to remove it. The addition of a little manure to the soil and plentiful watering would soon restore the green colour.

FORCING AND INTERMEDIATE HOUSE (*S. S.*).—The cheapest and best description of house is a span or half-span, both of which are shown by sections at page 274, vol. vii., New Series. We should prefer the half-span with the ends east and west, front wall 3 feet high above ground, back wall 5 feet, height of house from floor to ridge 7 feet 6 inches, length of back light 5 feet, front lights 9 feet 6 inches long, lights for ventilation on the south side of the house 2 feet 6 inches wide, opening the whole length of the house by rod, crank, and lever apparatus. Pathway directly under the ridge 2 feet wide, affording a bed in front 5 feet 6 inches wide, and one at back a little over 2 feet wide. The forcing house should have two rows of 4-inch pipes beneath the front bed, and one at the back to afford bottom heat, surrounded by and covered with rubble to a depth of about 6 inches, and upon this 9 to 12 inches depth of plunging material. No bottom heat will be required in the intermediate house. Three rows of 4-inch pipes will be required for top heat in both houses—i.e., two along the front and one alongside the pathway, but as there is no saving in pinching for piping we should have four pipes in the forcing end, and three in the intermediate house. A fair proportion would be 16 feet length of forcing house, and 20 feet intermediate house, but all depends upon the requirements.

PEAS DISEASED (*O. A. Subscriber*).—The pods enclosed to us by you are infested with thrips, there being traces also of mildew. The remedy is to afford copious supplies of water in dry weather, pouring the water along the sides of the rows, and mulching with short manure. The pests may be destroyed by syringing the plants with a solution of soft soap, 2 ozs. to the gallon of water, after the Peas have slatted. Lining will improve the staple of the soil by liberating its pent-up organic substances, but it will not keep crops from the ravages of thrips.

PLANTING IVY UNDER TREES (*A Constant Reader*).—Ivy may be planted any time in mild weather from September to April inclusive, and all the year if the plants are from pots. We should plant in February or March, and sufficiently close so as to cover the ground quickly, pegging the shoots over the surface in all directions, and keeping the soil moist until the plants are established. Cuttings will not be likely to answer, as the soil will be too dry to ensure their speedy growth, but they may be inserted now in a shady border in rather poor light soil, where they will root freely if kept moist.

FRUIT TREES FOR SLOPING GROUND (*G. Holme*).—It is of primary importance in fruit culture that water does not lodge in the subsoil. If the ground be wet superfluous water must be carried off by drains placed 6 to 7 yards apart, and not less than 3 feet deep, having proper falls and outlets. With this and trenching the ground 2 feet deep we do not think you need fear forming a fruit garden with a variety of fruits. But you do not say whether you intend to form it into an orchard, keeping in grass or breaking-up the sward; but as you mention half-standards we presume it is to be kept in grass; therefore our answer to your queries, as tabulated, is—1, We should not plant Apples only. 2, Standards or half-standards trees should be planted 24 feet apart. 3, Plums, Pears, and Cherries would be likely to succeed, but Apples and Plums are most likely. 4, The failure of the Black Currant bushes is probably due to excessive moisture, probably a sour soil induced by stagnant water, or it may be poverty of soil. Destroy the old bushes and plant fresh ones in new ground of such kinds as Black Naples and Lee's Prolific. 5, Standard trees do not require any lifting, but root-pruning if they are growing too vigorously is occasionally necessary. 6, As to kinds of

Apples—Kitchen: Cox's Pomona, Bedfordshire Foundling, Dumelow's Seedling, Warner's King, Lord Suffield, and Northern Greening. Dessert: Dutch Mignonne, Sturmer Pippin, Blenheim Pippin, Irish Peach, Cox's Orange Pippin, and King of the Pippins. Plums: Early Prolific, Orleans, Diamond, Prince Englebert, Victoria, Wyedale, and Crittenden or Cluster Danson; those for culinary purposes. Dessert: Oullins Golden Gage, Green Gage, Jefferson, and Kirke's. Cherries: Downton, Empress Eugénie, May Duke, Bigarreau Napoleon, and Morello. Pears: Jargonelle, Williams's Bon Chrétien, Beurré de Capiaumont, Marie Louise, Beurré Diel, and Jules d'Airolles, with Catillac for stewing.

CULTURE OF FILBERTS (*C. A.*).—The Kentish Cobs raised from seed and now 4 feet high will bear heavy crops of nuts in due course, but you must be content to wait three or four years till the branches have become sufficiently large to yield fruit. When the leaves fall cut down the seedling plants to within a foot from the ground. Next spring young shoots will cluster thickly upon the stem. Rub all off but four or five of the strongest, and when these are a couple of feet in length nip off the tops of each to induce a lateral growth of side shoots, all of which except a couple of top shoots must be pruned to form spurs when the leaves fall, the two upper shoots being shortened slightly for a new lateral growth in the following season. The best form for each tree is that of a basin very wide and shallow. This form may be imparted to some sorts by judicious pruning, but most kinds require some slight training by pulling down the young branches and fastening them in the right position with string to pegs driven in the ground. Be sure and keep the centre of each tree open, or you will only have nuts upon the upper branches instead of right down to the bottom of the tree. We have tried several varieties of Nuts and Filberts, and find Kentish Cob the most robust and prolific of them all; not a summer passes without some nuts being had, and in most seasons we have a full crop.

GRAPES SCALDING IN LATE VINEY (*Idem*).—The best remedy is to afford full ventilation for a week or two till all risk of injury is past. Remove flat plants from the house, thin crowded growth, and see that there is not the slightest obstruction to a free circulation of air. Take care also that the roof ventilation is thorough. You will find fuller notes on scalding in another column.

CABBAGE LEAVES EATEN BY INSECTS (*Alexander Boyle*).—The Turnip fly (*Athalia spirarum*) eats the succulent green part of the leaves, and leaves the membrane of veins; but then it usually makes clean work, and as you say the mischief is done at night we are inclined to attribute it to some nocturnal weevil—which we cannot say out of the five hundred known British species of these destructive insects, and probably many more unknown.

RAISING CLEMATISES FROM SEED (*Amateur*).—If Clematis seed is sown early in the year and the pots plunged in gentle heat it germinates freely. If your seed had no heat and the pots were placed in a cold pit or frame the soil may have become sodden with moisture at some time and the seed has decayed. If it is still sound the seedlings will probably soon appear, and if so encourage the growth by keeping them in gentle heat after they are potted, so as to have them as strong as possible by winter, when the growth will very likely die. Place them then in a cool pit or greenhouse, keep the soil moist but not sodden, and in spring you will be rewarded by a strong vigorous shoot pushing up through the soil, and by attention to the necessary repotting and watering the plants will soon gain sufficient size to yield flowers.

SEEDS AND BULBS FROM SOUTH AFRICA (*Stirling*).—The bulbs will probably thrive in warm sheltered borders in the open air, but it will be well to pot most of them immediately, as spring time at the Cape is fast approaching, or rather may be said to have come. The *Aponogeton* and *Richardia* which we have established in the open air are both now in full activity, putting forth new foliage abundantly, and the seed of *Aponogeton* is germinating by hundreds. Pot the bulbs and place them in a cold pit, removing them to the greenhouse for winter; water them regularly after the blossom fades until the foliage is perfected, in order to impart full vigour to the new bulb; then gradually withhold water, and repot the bulbs after a period of a few weeks' rest. If you have plenty of duplicates by all means try some in open borders, protecting with ashes in winter. The seed should be sown now, and the seedlings be repotted from time to time and kept in full growth during winter in a greenhouse, or better still an intermediate house if you have one, but if you cannot afford space under glass it will be better not to sow till spring.

NAMES OF PLANTS (*W. J. B.*).—We cannot name plants in their leaves only. (*A Constant Subscriber*).—1, *Lysimachia vulgaris*; 2, *Lysimachia* sp.; 3, *Clerodendron*. (*W. H. P.*).—1, Clematis sp.; 2, *Sagina nodosa*; 3, Much too young to determine; 4, *Lomaria alpina*. (*Young Gardener*).—1, *Lysimachia vulgaris*; 2, *Geranium sanguineum*; 3, *Aster puniceus*; 4, *Aster lœvis*; 5, *Bupthalmum salicifolium*; 6, *Centaurea montana*, (*Tyro*).—3, *Oenothera biennis*; 4, *Hypericum perforatum*; 5, *Lopezia racemosa*; 6, *Hemianthus puniceus*.

THE HOME FARM:

POULTRY, PIGEON, AND BEE CHRONICLE.

HARVESTING OF OATS.

It is often said that oats being an inferior grain compared with either wheat or barley, the harvesting of the crop is not of so much consequence, and that we need not be so particular as to the condition at harvest as for other crops. This idea used to prevail formerly much more than at the present time, as we have known parties carting oats to the rick when the straw was very damp and even when it rained; but the straw is now so valuable that we are, as it were, bound to have the straw in good condition, and thereby we save the grain in a valuable state. Although the oat crop may be inferior in comparison, yet in some of the northern and western counties, in the hill

districts and in exposed situations along the coast, it is the only grain crop grown, and this circumstance, together with the difficulties of harvesting on the elevated lands and backward climates, makes it desirable to select such varieties of oats as will not readily shed or whip-out by the wind. On the other hand, it is desirable to grow a forward sort of grain in order to its early harvesting in the most unfavourable districts. The winter-sown in the autumn will come earliest to harvest, and this sort, as well as the Potato Oat, the Hopetown, the Poland, and Black Siberian, each of these kinds is adapted in some respects for a backward climate. Still they are open-hawed, and in exposed situations it is very difficult to secure the crop without loss by shaking. Under these circumstances they should be cut very early and tied into sheaves. These are, however, sorts which recommend themselves to our notice by the fact that, being close and cluster-hawed, they will stand almost any amount of wind without loss of the grain. These are the Black and White Tartarian varieties, and they are capital croppers; but the white sort is rather late and not quite so well adapted for the northern climate. It is, however, invaluable for growth in elevated and exposed districts; for we have never known it shed the grain, and it has been lately very much improved as a pedigree oat by careful selection, and the grain is now much superior to what it used to be, and the straw of this sort is excellent food for cattle.

The oat crop is rarely ever cut soon enough, and it may be said as a rule, that when the straw is turned yellow the sooner the crop is cut the better both as regards the value of the grain and straw as fodder, because a portion of sap will then be in the straw, and when properly dried before harvesting contributes greatly to its feeding value. If the crop is allowed to stand until fully ripe of all the open-hulled sorts, such as the White Canadian, the Winter Oat, and the other sorts before named, they can scarcely be harvested without serious loss, even when cut and tied, for the grain will fall out greatly even in the act of cutting and tying. The Tartarian varieties, both Black and White, are now very much in favour even on the best lands and superior climates of the southern and eastern counties, for they will not only yield an abundant crop both of straw and grain, but they may be allowed to remain uncut for a considerable time if other more urgent work requires immediate attention. They will also when cut, tied, and stood up in shock, remain without serious injury in case of a showery or wet harvest. We have found the White sort in good condition after standing in shock for a month; but there is a point to be considered in all cases where the crop is sheaved and allowed to stand a considerable time in shock. It will perish the clover plants under the shocks; and as it is a common practice to sow clover in the oat crop this is an important consideration, and there is no way of saving the clover except by constantly, or every three or four days, removal of the shocks on to fresh ground.

The reaping machine and self-binder is as well adapted for cutting and tying the oat crop as for wheat. But in case of wire being used for binding the sheaves it will prove very difficult to deal with unless the wire is removed from the sheaves at the time of thrashing, which will prove not only expensive but cause delay. On the other hand, if the wire is passed through the thrashing machine with the straw it proves a serious evil, being mixed up with the straw when used for fodder, whether the straw is given to the cattle whole and loose, or whether it is cut into chaff; in fact, it cannot be cut into chaff without great difficulty, and if it could be accomplished there is still the liability of injury to cattle swallowing the small pieces of wire with the chaff. The tying of the fodder crops either of oats or barley with wire must be abandoned, and the sheaves tied by hand with straw bonds, until some further improvement and discovery is made as to binding materials. Tying with yarn has been attempted but has failed, and even if it had succeeded as a tying material it would be very objectionable to be cut up with straw as food for cattle. We have sometimes found that when the crops of oats are very abundant, that the straw will be much

laid and twisted. In that case it will be often advisable to resort to the use of the fagging hook for cutting, as the means of saving the most grain and straw, more particularly of the tender and delicate sorts of white oats. It is also desirable that the sheaves should not be tied very large, say from 14 to 15 inches through at the bond, for in case the sheaves get wet outside by rain, or tied-up when wet, they will not get dry so quickly as wheat. Oats have so much more leaf attached to the straw, and it entails so much labour and loss to untie the sheaves, that there is always more liability to heating in a rick of oats than of wheat, especially when the crop is seeded with clover. In this case the crop will be required to stand much longer in shock.

Cutting oats with the scythe and carting to rick as loose corn is still practised where the crop is light, and no doubt it becomes fit for the stack sooner, but in case of rain the turning of swathes and the changes from wet to sunny weather bleach the straw and seriously injure the fodder. Should, however, the weather prove fine, the loose crop soon becomes fit to harvest. In stacking the loose corn there is always more waste than when tied, and the rick of loose corn will require to be carefully thrashed with sticks on the outside, or some corn will be taken by small birds; whereas when the oats are tied the butts of the sheaves furnish an outside to the rick without loss. We also like the ricks made round, and if required to stand for a considerable time the ricks should be placed upon a stand, as rats and mice are both especially fond of oats.

WORK ON THE HOME FARM.

Horse Labour is now most important, particularly when it is a common practice to turn the horses out to grass during the first few days of the harvest month, and set the teamsmen to work in the harvest field. We, however, have always demurred to this plan, believing that the labour of horses is too valuable to be thus thrown away. We usually have ploughing and sowing turnips for them to do after peas, winter oats, early white oats, or wheat. In case we do not sow stubble turnips we always take care to keep the horses at work in fallow-ploughing or scarifying, whichever may be best, often between the shocks of corn, otherwise after the corn is cleared. We hold the working of horses continually to be sound practice, for it must be admitted by any person with experience that horses to be in good health and equal to their work when called on at all times should be fed well and worked with regularity. We must also bear in mind that horse labour upon the land is valuable in proportion as the weather is favourable and the land dry. Some horses, too, will be required in working the reaping and mowing machines, and this is severe work even for powerful and active animals. It is advisable, therefore, to have this work done by relays of horses, so that the reaping should be done without any hindrance; and by taking fresh horses every four hours the animals will not be overworked nor the reaping retarded. As soon as the stacking or housing of corn commences one of the horses will be required to work the gear of the elevator in making the ricks, whether of wheat or sheaved oats, or of loose corn, such as peas, oats, or barley.

When the cultivation of a farm is of a mixed character the horses are enabled in autumn to till all the land required for early root crops, such as potatoes, mangold, carrots, &c., without the aid of steam power. Upon this system of tillage we are nearly always busy with our horses without being subject to heavy pressure of horse labour, which often occurs upon farms tilled or sown upon the four-course rotation, and it often happens that extraordinary pressure takes place twice a year—viz., preparing for wheat out of lea and preparing for turnips after a winter fallow; whilst at other times of the year the horses are comparatively idle, or employed in some unimportant work. In many cases the question of supplementary animal power is a matter worth more consideration than it usually obtains, particularly since the introduction of steam culture, and which is not always available for the home farm, even by hiring. We allude to the working of oxen for tillage. We will not here, however, enlarge upon this matter, preferring at a future time to take up the subject for a special article. In securing corn we do not advocate its being housed in the barns, except such portions of the crop as may be required for thrashing immediately after harvest, because the damage by such vermin as rats and mice is often very serious when corn is kept in the barns during the winter months.

Hand Labour will now be required for tying the corn behind the reaping machine, at least upon those farms where the combined reaping and binding machine is not yet in use, and also hand labour will be required in assisting to stack the corn. In most cases, however, the elevator is now used on the home farm, and the labourers ought certainly to appreciate its use, taking off the men, as it does, the severest manual labour which they can be

called upon to do during the harvest. Women also should be encouraged to do work during the harvest month, for many of them have been accustomed to tie the corn reaped by their husbands. Some of them are, therefore, as capable of tying behind the reaper as the men, and this work should be let by the acre to men who have wives and families, which not only forwards the work but enables the people to earn good wages.

The management of pigs must not be overlooked, it being part of the work on the home farm to see that the swine of all ages are well cared for, so that not only the animals themselves may be in good health and condition, but that the breeding sows should be carefully attended and properly fed, in order that they may bring their young in due course, and both mother and offspring be maintained in good health. It, however, must not be forgotten that these animals are not very profitable in breeding and rearing if their dung and droppings are left out of the calculation. It is in consequence very desirable that the store pigs and also breeding sows should be fed daily in part with vegetable produce of the land, such as clover, vetches, rape, trifolium, Swedes, or turnips, whichever may be in season, with a small allowance of Indian corn or barley meal, and the animals accommodated with pens such as will be described on a future occasion.

HEDGES AND THEIR ENEMIES.

FENCES interest everyone who occupies a rood of land, and yet how rarely one sees a farm properly fenced! The expense of maintaining a bad fence is so onerous that it is worth while doing the work thoroughly well when the fence is first formed. The main thing requisite is to have the land clean and in good heart, so as to get the young plants well started. Plant in double rows in zigzag line, and cut them back within 4 inches of the ground in the third year. Never plant them on a raised bank, a very common practice, and have them pruned by a skilful workman with the sharpest of bills every year, aiming at a wedge shape, thus—A. Holly is the only powerful ally of the hawthorn; but unfortunately rabbits, the bane of the planter, are fonder of that beautiful shrub than almost of any other. And coming to the pests which destroy our best efforts when rearing a young fence, I ask your opinion of the specimen I forward of one which during the last three weeks has attacked a thriving young quickset fence which I had cut down last spring. Three weeks ago it was looking as well as possible, and when I again saw it yesterday I fancied that some urchins had been firing the grass and had scorched the fence (as one often sees along railway slopes portions of the fence scorched by fire ignited by sparks from the engine), the leaves and shoots being brown and crisp, with no sap whatever left in them. I could find no living grub on any of the portions that were quite brown, but on some shoots just beginning to change colour I found the minute orange-coloured maggots, some of which I forward, and which I presume to be the destroyers of my beautiful young fence. I hope that this scourge is not common in the country, for on a large scale it would be a most serious evil.

I have also found a wooded ravine, where oaks form the principal growth, overrun with caterpillar. My notice was first attracted by minute black specks on the light sandstone road, which for two miles looked as if black pepper had been strewn from a castor upon it. I soon discovered, however, that these specks were the excreta of countless multitudes of caterpillars, which since my previous visit had attacked the oaks. How disheartening these visitations are, and how inscrutable!

A check in the free circulation of the sap arising from inclement weather, and thus weakening the vitality of the tree, is nearly sure to be followed by an attack of this hateful pest. Should this occur in two successive years many trees will succumb under the attack. How does this devouring host suddenly acquire vitality by reason of the weakened condition of the tree growth?

The invasion of the quickset by the grub I have referred to occurred during the recent hot weather, so that the cases are not parallel, and I am utterly at sea with regard to the origin of both infestations.—W. LIPSCOMB, *Heath, Wakefield* (in *Journal of Forestry*).

FORTHCOMING POULTRY SHOWS.

WE have before us the schedules of several shows, which will be interesting, as likely to bring out many of the best early chickens of the year, and so to give us some idea of the quality of the year's produce. We have before commented on the Winchester schedule, the first show, we believe, of the season for chickens alone.

Bath, as usual, has a most attractive programme. We regret to hear that the former shows held there have resulted in considerable loss to the Committee, and that this show is a kind of test as to whether there is a real desire among fanciers for a continuation of the meetings. There are twenty-one cups and special prizes, besides two point cups. The poultry classes are forty-three, with three prizes in each of 80s., 10s., and 5s. Save in the case of Silkies, Bantams, and Ducks, which are shown in pairs, the classes are for single birds, chickens of the year. In these specially

excepted classes and the Selling classes birds of any age are admissible. Pigeons are for the first time at Bath shown singly, and have twenty-seven classes with prizes of 15s., 10s., and 5s. Cage birds have nineteen classes and Rabbits eleven. The Rev. Grenville Hodson is as usual Judge, but will this year have a colleague not yet appointed. The Show days are Sept. 4th and 5th.

The Central Bucks Agricultural Association will this year hold its meeting on September 11th at Wycombe Abbey, High Wycombe, in lieu of at Aylesbury. The poultry classes, twenty-eight in number, are for birds of any age, for the most part shown singly, with three prizes in each of 25s., 10s., and 5s. There are twelve cups, one of five guineas, the rest of three and two guineas. Pigeons have eight classes, with prizes of 10s. and 5s. and a two-guinea point cup. Canaries, three classes, with prizes of 15s., 7s. 6d., and 5s. Mr. Hewitt is appointed Judge.—C.

RABBIT COURTS.

As soon as the young Rabbits are large enough to be removed from the parent exercise will be found very necessary to keep them in good health. They may be kept in large hutches and occasionally put down to run. This gives some trouble, and does not always answer. What is most suitable under the circumstances is a place where they can constantly run about and gambol, and where they can keep dry and warm. A properly constructed Rabbit court will answer all these requirements and pay well. If the soil is dry and solid there will be every chance of success.

The best place for a Rabbit court is in a yard with a hard well-trodden-down bottom. The best part of the yard is a corner made by two houses, or, failing this, a house and a yard. These will greatly diminish the cost of making the court, and the building will keep off wind and cold. Regulate the size according to the number of Rabbits that are going to be kept in it. Suppose you are not going to put more than fifty young Rabbits in at a time, and that you will weed them off as they grow older, about 60 square feet will be plenty. Each wall should be at least 6 feet high, or the place will not be healthy. If the two sides already erected are very strong a single course of bricks may be sufficient for the extra ones; but if the thickness is only 4½ inches, a couple of buttresses double that thickness should be placed so as to act as a support for each wall. A roof should be added to keep off the wet—at any rate the worst of it. To effect this a lean-to of 2-inch boards will be found handy, and these should be screwed tightly together by means of cross pieces. They should be put up in hot weather when the wood is dry, and then the wood will swell with the wet and effectually keep out any rain. If put up in the winter the wood will shrink with the heat and leave crevices of as much as half an inch in the summer. The whole should be thickly tarred on the outside. If the wood is old and not likely to be quite watertight, it can be made equally effective by nailing along it a piece of felt and then having it well asphalted. New timber is the cheapest and most effective. The part against the wall may be 7 feet from the ground, and the other extremity only 6; but if the length is much the slope should be increased, the top to be 8 feet from the ground and the bottom still 6. There will then be a small space left open between the roof and the top of the walls. This may safely be left for light and ventilation, and to prevent the wet beating in the roof may be made to project a few inches. A door must be made in one of the sides. This cannot be made very easily, as it is necessary to make it strong or the whole side is likely to fall in. For economy's sake many make the doorway very low, so as to make creeping in almost necessary. This is very unsatisfactory. On the other hand, if the door is high, say about 5 feet, and a few inches more is an advantage, a dodge may be resorted to to prevent the Rabbits from running out when the door is opened. Two grooves may be fixed on either door-post and a plank slipped down, as is often done in country cottages to keep the children in. If it is not more than a foot high it will not be much trouble to step over, and it will prevent many a chase after a delinquent. A better plan is to make an entry in two doors, as is done in the case of aviaries, but this is very much trouble and will add to the expense. The floor should be carefully prepared. If the ground is gravelly or sandy and pretty hard the best floor will be an inch layer of cement and sand mixed up very wet, poured on, rubbed smooth, and left to dry. If the soil is at all damp, 2 or 3 inches of sand or gravel should be laid down and the cement on the top of it. In either case the result will be a floor of great hardness and durability. For the purpose of draining it should be allowed to slope a little towards one corner or side, and if possible connection should be made with some drain. In the centre of the floor a couple of bushels of soil quite dry and clean should be placed so that the Rabbits can sport on it and perhaps burrow a little. As it is liable to fall in and cause suffocation it is best not to pile it too high. Along one side of the court a trough something like a pig trough, but about a third the size, should be fixed. Wires should be fixed along the top to prevent the Rabbits from getting in. It should be made of metal, or if of wood a piece of wire should be fixed along the top so as to keep the Rabbits' teeth from destroying it. Especially during cold weather, and at all times, the little

Rabbits will require some place of warmth to go into at night. Along another side a place 2 feet wide, with a top to open on hinges, will be sufficient. Half a dozen holes should be cut in it to allow the Rabbits to run in and out. If wished two or three partitions can be placed on the outside, but they are not needed. They keep the place a little warmer. This must be kept well filled with straw; a little hay may be given, but as the Rabbits will eat this it should not be relied on for bedding.

Such a place as this will be very useful for young Rabbits in the summer and autumn, but it will be found cold in winter, when it may be used as a rabbitry for varieties not requiring heat.—G.T.A.

VARIETIES.

OWING to the heavy rains that have fallen harvest operations are suspended in some districts, and injury has been done to the grain by the extreme violence of the storms. With the storms a high temperature has generally prevailed; a continuance of those conditions can scarcely fail to promote the sprouting of grain and to accelerate the spread of the potato disease. The showers, except where they have been excessively heavy, have much benefited the root crops, which, and also weeds, are now growing rapidly.

— AT a large and influential meeting of the members of the Highland and Agricultural Society recently held in Edinburgh, his Grace the Duke of Buccleuch presiding, Mr. Fletcher Norton Menzies, the Secretary of the Society, was presented with a cheque for the handsome sum of £1225 19s. 2d. and a massive silver tankard as a mark of the high appreciation entertained by the members of the Society of his services as Secretary during the last twelve years, and of his successful exertions and devotion to duty in promoting the usefulness and interests of the Society. The subscriptions were limited to five guineas, and the list contained the names of 671 members, the total amount subscribed being £1320 11s., which, after purchasing the silver tankard and deducting all expenses, left the handsome balance of £1225 19s. 2d., for which a cheque was handed to him by the Duke of Buccleuch, who in making the presentation paid a merited tribute to the careful assiduity and managing ability of Mr. Menzies.

— WE hear that considerable interest in poultry has of late been aroused in South Germany. Some of the best specimens of Dark Dorkings in the Early Wood yards have lately gone to more than one fancier in the neighbourhood of Dresden.

— AT the Council Meeting of the Bath and West of England Society, held on the 30th ult. at the Grand Hotel, Bristol, the Chairman feelingly referred to the great loss sustained by the Society by the death of Mr. Charles Gordon, who for many years had rendered efficient service as Member of the Council and Steward of one of the principal departments of the Society's Exhibition; of Mr. Herbert Williams, who as Chairman of Finance, and in other prominent capacities, had served the Society with indefatigable zeal; and of Mr. Bremridge, whose munificent hospitality on the occasion of the Barnstaple meeting would be ever memorable in the history of the Society. The Finance Committee brought up their quarterly statement of accounts, and payments to the amount of £5719 0s. 8d. were sanctioned by the Council. It transpired that considerable loss had been incurred by the recent Oxford Meeting, and the Finance Committee were authorised, should they find it necessary, to sell out £1000 India bonds. The Committee appointed to visit Exeter and make arrangements for the Meeting of 1879 presented their report, and it was resolved that the site opposite the Barracks on the Topsham road be accepted, and power was given to the Committee to conclude arrangements with the local authorities. The Council having at a previous meeting received an invitation from the authorities of Southampton for the Society to hold its meeting in that important town in 1880, a further communication from the authorities of Southampton was now presented by the Hon. and Rev. J. T. Boscawen, and a deputation was appointed to visit Southampton on an early day to inspect the proposed site and make other arrangements preparatory to the next meeting of Council. On the motion of Colonel Luttrell the sum of £2070 was placed at the disposal of the Stock Prize Sheet Committee for the Exeter meeting; this amount, being £70 in excess of that offered at any previous meeting, having special reference to the claims of breeders of Channel Islands stock. Owing to the large amount of business to be transacted the consideration of the prizes to be offered for poultry and in other departments was deferred until the August meeting.

— SINCE we are so greatly indebted to America both for farinaceous and animal food, the following extracts referring to the future supply possess interest:—The present wheat crop will be grown on an area increased to make up more than the deficiency of the last. Its extent is not yet fully determined, but the increase will probably reach four million bushels, and the entire field will comprise not much less than 30,000,000 of acres. Nearly every winter-wheat State shows an enlargement of area, small in the eastern and middle, variable in the south, reaching 22 per cent.

in Texas and 18 in Tennessee. In the eastern half of the Ohio Valley (Michigan, Ohio, and Kentucky) the increase appears to be about 500,000 acres, and in Indiana and Illinois more than 700,000 acres. There will be an increase of nearly 400,000 acres in Kansas, and 300,000 or more in Missouri. In round numbers the increase in the spring-wheat States may be placed at 2,400,000 acres. In the four spring-wheat States of the north-west there is a large increase, as well as upon the Pacific coast, the extent of which is not yet determined, but it will be likely to approximate 1,500,000 acres. Of condition both of winter and spring wheat little need be said, except that it is fine, not to say extraordinary, with very few exceptions as drawbacks as yet in any part of the country. If the yield shall prove an average one the crop must be as large as that of the past year, equal to a liberal supply of home wants and export demand somewhat larger than the average. —(New York Tribune.)

— IT may be interesting to those poultry fanciers who have not received their Paris prize money in full, or who have received bronze medals in lieu of medals of a superior metal, to know that one of the English jurors has addressed a remonstrance on this (as he conceives) departure from the promises of the published schedule, to the authorities, and has been promised that the Minister of Agriculture and Commerce will have the matter inquired into at once. The English jurors on the conclusion of their labours in Paris were given to understand that gold medals would be given to them as little souvenirs of the great International Exhibition. They are now informed that this was purely an error on the part of the President of their section, as no such medals were ever cast or decreed to them!

— IN an interesting paper on dairy farming recently read by Professor Sheldon, it is stated that the enormously increased demand for fresh milk, coupled with facility of railway transit, is rapidly changing the character of dairy farming, and it is well for the dairy farmer that it should be so, for it is far more profitable and satisfactory in many ways that he should sell his milk as milk, and not convert it into cheese and butter—as much of it, that is, as he can arrange to sell in that manner. This system, however, is making us as a nation more and more dependant each successive year on foreign cheese and butter; and it is more than probable that we shall soon become almost wholly dependant on them for these most useful and valuable articles of food. Owing to the greatly increased consumption of milk the production of cheese and butter in this country is annually decreasing, and this is also the reason, the chief if not the only reason, why cheese factories have not gone on multiplying in number in the midland counties.

— AS showing the importance of sheep husbandry in various countries of the globe, the *Prairie Farmer* states that Great Britain has one sheep to each two acres of land; Germany, France, and Spain one to each five acres; the United States one to each fifty-six acres. There is no farm animal that with proper care will do more for a worn country than sheep. So well known is this that their tread has been called golden. It is so, inasmuch that while paying well for the care bestowed on them they are constantly enriching the soil on which they feed by their droppings. It has also been said that sheep pay twice—once in the fleece and once in carcase.

— THE American Minister for Agriculture has recently stated that in the extensive caverns of Texas enormous masses of guano are deposited. The quantity is estimated at 20,000 tons, and the quality is said to be superior to that of fish guano. Its origin must be looked for in the immense numbers of bats which inhabit these caverns. It is also reported that in the Indian Ocean several guano islands have been discovered, so that the threatened exhaustion of guano deposits need not be feared for some time to come.

BEEES IN BRITTANY.

WHILE recently travelling in Brittany we noticed as far as we could the local peculiarity of bee management. Hives were large, made of straw, shaped like our old-fashioned bellglass supers—i.e., narrowing at the base. As many as forty-nine were counted in one small field by the roadside, arranged in a double row, each upon its separate slab of stone laid flat upon the ground and covered with a sod of earth. In other places we saw the hives ranged one on the top of the other very close, with a bank behind them. The entrances were very large, shaped much like an egg when lying on its side, allowing free egress and ingress. About 20 lbs. of honey was stated as a very fair yield in good years. Brittany is generally a poor half-cultivated country, but it ought to yield at times an abundance of honey from the prevalent crops of buckwheat. If broom is a honey-yielding flower much ought to be gathered from it, as it too is found everywhere in great abundance. Like all hungry soils lying on a substratum of granite there is no lack of heather in places, which in fine seasons must also be productive. The present season appears to have been very similar in character hitherto to that experienced by ourselves. The people spoke of a wretched spring and a wet early summer, which was followed, as in England, by great heat and heavy

thunderstorms; accordingly we found swarming going on quite late in July—so too we found it in Jersey, nor did it seem to be thought an unusual circumstance.

Owing to the Bretons being rarely able to understand French, as they talk a language of their own akin to the Welsh and Gaelic tongues, it was difficult to get any more precise information from the peasant bee-keepers, who alone appeared to keep bees.—B. & W.

FERTILE WORKERS.

A BETTER illustration could not be found as to how the deeper mysteries of apiarian science are to the skeapist a sealed book, while to the bar-framer these are laid naked and bare for inspection, than in the case of fertile workers. Years ago in these pages while, the late Mr. Woodbury, the "REXFREWSHIRE BEE-KEEPER," and myself were discussing that interesting but by no means very rare phenomenon, Mr. Pettigrew in the columns of the "Scottish Gardener," treated the subject as follows:—

"Both ancient and modern writers on bees since the days of M. Huber have said a great deal about fertile workers. They tell us that some working bees lay eggs; they tell us how these fertile workers are produced, and describe their size and colour. I wish here to move an amendment, and to meet the statements of these writers on this point with a direct and positive contradiction. I fearlessly affirm that there never was and never will be a fertile working bee; and let me here cast the burden of proving their existence on the shoulders of those who write about them. If there should be one fertile worker in all England or Scotland this year I will here offer £10 to the owner if he will send her to me; and if he does not want to part with her I will give him £10 for the poor of his parish if he will send me a dozen of her eggs. And let me hope that these writers will hold their tongue about fertile workers till they honestly meet my challenge and offer and produce one of what they write about."

There at present stands in my apiary remains of a stock of black bees, now thirteen months old, which this season failed to raise a queen from Italian eggs supplied. A substitute—a fertile worker—as usual in such circumstances, took her place. She, her treatment by her unfertile sisters, her eggs, and Italian drone progeny hatched therefrom, are freely open to the inspection of all bee-keepers interested on the point at my apiary, Auchenaith, Blantyre, Lanarkshire, and it is my intention, should no accident befall in the interim, to exhibit the same in a small observatory at the Caledonian Apiarian and Entomological Society's Exhibition in connection with the Highland and Agricultural Society's Meeting at Dumfries on 30th July.—A LANARKSHIRE BEE-KEEPER.

HONEY HARVEST OBTAINED FROM STEWARTON HIVES.

JULY 29TH.—I have removed the supers from my two Stewarton colonies, and the results, if not equal to those I have formerly recorded, are I think, if the character of the season is taken into consideration, highly satisfactory. Up to the 21st of June I do not think that there was a single sealed cell of this year's honey in my apiary.

Only two stocks were storified; of these one has yielded 56 lbs. 12 ozs., the other 53 lbs. of pure virgin honeycomb. A third colony established last summer in a neighbour's garden has completely filled and sealed three supers containing fully 60 lbs. of beautiful honeycomb. In all these supers (ten in number) there is not a single cell which has been polluted by the presence of either brood or pollen.

As an experiment I have had a set of Stewarton boxes constructed of a larger size than usual. The stock boxes are 16 inches in diameter and 7 inches deep inside measure. The supers are of the same diameter, but only 4 inches deep. Three stock boxes make up the set. A swarm was introduced into one of these boxes on the 15th of June, a second box was shortly placed under the first, and a super was placed on the top. Both of the stock boxes are now fully occupied, and the super which was removed yesterday contained 17 lbs. 8 ozs. of beautifully white honeycomb.—J. E. BRISCOE, *Albrighton*.

OUR LETTER BOX.

SUPERS NOT FINISHED (*J. C.*).—In order to prevent your bees from swarming you put a super on the hive on the 6th of June, which was filled with combs in a few days, when a second super was placed beneath the first. In the course of a few days the second super was filled with bees and combs, when you put another beneath the first and second ones. These three supers you say are filled with combs, but not with honey. Your management has been good, only the season has been unfavourable for honey-gathering. If it had been a honey season you would doubtless have got three supers full and finished from one hive. If the bees were on Bagshot Moors they would soon finish the supers. If you do not take them to the heather we advise the removal of the supers. Probably you will find several pounds of honeycomb in the topmost super. If the combs in the others are white they could be preserved for use next year. If the stock hive weighs beyond 40 lbs. the bees could be driven and fed and its honey taken.

MAKING CAPONS (*S. Langdale*).—The operation of caponising is so cruel and unnecessary that we cannot recommend it. Fowls properly fattened will attain a sufficiently large size without being converted into capons.

DRIVING BEES (*Novice*).—Your bees may be driven from their hives by anybody who has courage enough to blow some smoke from fustian rags into their hives amongst them, turn the hives on the crowns (upside down) and place empty hives on them mouth to mouth, and roll tablecloths round the junctions to keep the bees in. When this is done commence at once to drum on the bottom hives with both hands, or two books, or two pieces of wood, and continue this work for fifteen or twenty minutes. This drumming disturbs the bees so much that they run up into the empty hives. If you will only try it in earnest you will be astonished at your success.

WEIGHT OF HIVES FOR WINTER (*Tom Towner*).—From September till March an 18-inch hive well filled with bees will require from 15 to 20 lbs. of food, either good honey or syrup. Less of course will do for a smaller hive. Forty thousand bees (8 lbs. weight of them) are population enough for an 18-inch hive in September, and thirty thousand will be a fair population for a 16-inch hive. The more numerous the population the more food is required, and if the weather in autumn and winter be mild the more food is consumed. The estimate of 15 or 20 lbs. of food includes nothing but honey or good syrup at the end of August when the stores have all been laid up. When bees are working or being fed they consume a great deal of honey. Bees are now eating a great deal of honey and gathering very little. Every bee-keeper should know the weight, or about the weight, of hives and boards before they are put to use.

DEPRIVING BEES OF THEIR HONEY (*Leicester*).—We can give you no directions as we do not know what hive they are in.

REMARKS.

31st.—Fine morning, dull and oppressive from 11 A.M. till 2 P.M.; sunny afternoon; cloudless evening; bright starlight night.

1st.—Dull morning, followed by very fine weather rest of the day; cool breeze.

2nd.—Dull morning, slight drizzling rain, bright and sunny from 11 A.M. till 4 P.M.; cool breeze; cloudy from 4 till 6 P.M.; very fine evening.

3rd.—Fair morning, at 10.30 A.M. heavy rain with lightning and thunder; showery afternoon.

4th.—Thunderstorm at midnight with heavy rain, constant thunder from 1 to 3 P.M., and from 4.15 to 6.30 P.M. occasional showers; very heavy rain 6.33 P.M.

5th.—Rather damp morning, bright and sunny day, lightning from 8 P.M., heavy rain at intervals from 9 P.M. till 2 A.M.

6th.—Damp morning, warm and close; bright and sunny after 0.15, clouded over from 6 P.M.

All the means of maximum and minimum temperatures are about one degree above those of last week; but the dry-bulb temperature is nearly a degree lower. The barometer readings are rather higher than those of last week. Remarkably heavy rain on night of August 3rd-4th.—G. J. SIMONS.

COVENT GARDEN MARKET.—AUGUST 7.

OUR market does not recover its activity, as owing to the bank holiday and the recent heavy rains we have had very little to sell the last three days.

From observations taken near London during forty-three years, the average day temperature of the week is 72.5°; and its night temperature 50.8°.

AUTUMN PROPAGATION OF BEDDING PLANTS.

WHEREVER there is much summer bedding required the autumn propagation of the plants for the following season always requires considerable attention at this time of the year.

Provided good cuttings can be had they should be inserted as soon after the beginning of August as possible, and the whole should be finished by the end of this month at the latest to give the young plants a fair chance of wintering well. In a good autumn many kinds of cuttings will root freely and establish themselves during September, but this cannot always be depended on. We generally begin our autumn propagation about the 12th of August, and finish it all by the end of the month. During September the cuttings form plenty of roots, and at the same time they are fully exposed to the sun and air to harden them so as to withstand the winter without injury.

Some people prefer lifting and keeping old plants throughout the winter to propagating young plants: especially is this the case with Geraniums, but half a dozen old plants are not worth two autumn-rooted cuttings the following spring, as the old plants are always scraggy and rough-looking; and although they bloom well for a time the following season I have found they do not bloom so long as healthy young growing plants. Unless it is some kind we are very scarce of we never keep an old bedding Geranium over the winter, but we propagate considerable quantities of young plants. We root and winter them all in boxes 2½ feet long, 14 inches wide, and 3 inches deep. About a dozen holes are bored in the bottom of each box, a crock is placed over each of them, a little rough mushroom dung is placed over the whole, and then the box is filled up nearly level with a mixture of loam, sand, and leaf soil, or mushroom dung in a half-decayed state. Fifty cuttings are placed in each of the boxes, and at this rate the space required to winter boxes containing two or three thousand cuttings is small indeed. As soon as the cuttings are inserted the boxes are watered and stood at once in the open air fully exposed to the sun. Here they remain until early winter rains or frost demand their removal under glass, then they are shifted into a cool house, such as a vinery with the fruit newly cut, and no artificial heat is applied to them unless it is actually necessary. When they are shifted it is on a dry day, when the leaves are quite dry, and during the winter they are watered without ever damping the leaves. Treated like this we do not lose one per cent. of them during the winter.

But to return. In taking off the cuttings care should be taken not to disfigure the plants any more than can be avoided. The cuttings must not be all taken from one spot, but select them here and there over the whole bed, so as just to thin out the tallest of the shoots. No Geranium should be much longer than 8 inches or shorter than 6 inches. Where Geraniums are growing thickly many growths that look as if they would make good cuttings will be found close to the base of the plants out of sight of the surface altogether. Some might be inclined to select these as cut-

tings, as in taking them they would never be missed or disfigure the bed; but these undergrowths do not make good rooting cuttings, as they are too tender. Hardy points are the kind of cuttings to which preference should always be given, and this not only applies to Geraniums but to all other plants. In making Geranium cuttings it serves no good purpose to leave a lot of leaves on the points, as they only decay before the cuttings are rooted, and very often cause the cuttings to decay. All the leaves should be taken off but two or three of the very youngest at the points. These will grow into large leaves and form the principal part of the plants during the winter. When Geranium cuttings have been in about a fortnight they should be gone over, and all the dead and decaying leaves taken from amongst them. This operation must be repeated again when necessary. In dry weather, when the plants are beginning to root, they must be liberally supplied with water.

We do not strike Verbenas in boxes, but they are put closely together in 6 and 8-inch pots amongst a mixture of leaf soil, a little loam, and plenty of silver sand. As soon as they are inserted the pots are placed in a cold frame, and until they are rooted little or no air is admitted. On hot afternoons they are syringed and on sunny days they are shaded, but this is only until they are rooted, and after that air and sun is admitted in abundance to harden them off for the winter. Iresines, Alternantheras, Coleuses, and everything of this kind are rooted in the same way, and the results are always satisfactory.

None of the last-named plants are propagated in large quantities at the present time, as a hundred plants in spring will give two or three thousand cuttings.

The variegated Alyssum is another most effective plant that has risen very high in our estimation this season which requires to be rooted like Verbenas.

It is time enough to put in cuttings of Calceolarias by the middle of September, and then they need only be dibbled thickly in a cold frame. Pansies and Violas should be done in the same way; and when they are covered over with glass while they are rooting it should be removed immediately they commence growing, and they do best when they are aired very freely during the winter.—A KITCHEN GARDENER.

HARDY PERENNIALS.

SIGNS are not wanting that hardy perennials are gaining favour, slowly it is true, but surely, and it is certain that when next they do get a firm hold of our hearts and gardens they will become a permanent feature. Let no one suppose that because they are hardy they require less attention than tender plants, for the very reverse is the case, and it is in a great measure this very demand for attention which endears them to the enthusiastic grower, as it forces him to know them better and to become more acquainted with their individual peculiarities. There are certainly many beautiful things among them which will take care of themselves, and such as will do so are perhaps seen to the best advantage when allowed to assume a semi-natural habit by the margin of shrubberies, lakes, or whatever position seems to suit them

best. In such cases one kind of plant should be allowed to predominate in one place, or the weaker-growing or less hardy kinds would be speedily overrun. It is not, however, semi-wild gardening, enticing as the subject is, that I wish to speak of at present, but herbaceous, or, more properly, perennial borders, and these when once established will always afford ample material for the semi-wild spots.

Those who contemplate growing hardy perennials should be taking notes and making preparation at the present time. Such books and catalogues as I have had access to are of very little assistance in this matter, as so many plants are always enumerated which are only of secondary quality; nor are botanical gardens any great help, for although many valuable plants may be found there, there is such a mass of botanical and other curiosities to wade through, and when we do find a plant among them worth growing for its beauty the chances are that we cannot find the name in any nurseryman's catalogue at all, although the identical plant may be in several nurseries under another name. The best plan I have found for picking-up the necessary information, is by looking through nurseries with competent guides where such things are made a speciality and are planted out to show their natural habits, the said guides only giving us the correct nomenclature, and allowing us to take our own notes and form our own opinion. It is of no use to see plants in small pots, for although it is necessary to have most of them so grown to ensure safe removal, we cannot then judge of their habit.

As a rule hardy perennials do not look well in beds. A border from 4 to 8 feet wide and backed with shrubs is the place for them. If the boundary lines are irregular so much the better, but it is quite possible to make them look well against straight lines, and even in close proximity to a formal garden, but not forming a part of it. The borders I have charge of are in such a position, and although the formal garden comes in for the first share of applause it is soon over. You can see it all in a minute, and then comes the turn for the mixed borders, and I can assure your readers that in the majority of cases the longer people examine collections of hardy plants lovingly cared for the better they like them. It is stipulated that I grow nothing which does not flower after June, so that probably the best half of the hardy plants are denied a home here; but that leaves ample material to form a very interesting collection, and it makes a much better display at the time it is required than could be made if plants were used which flower at all seasons. I should always advise planting this class of plants according to their season of flowering, dividing them at least into spring and autumn sections, the spring arrangement being placed where it need not be seen by ordinary visitors after its principal flowering season is over. Of course plant lovers, who invariably live a good deal on imagination, would enjoy it at any time, but we have to please the many.

A well-drained soil is of the greatest importance, and on the whole the staple ought to be light rather than heavy. Peat, where it can be had sufficiently cheap, is a great boon, as it does not harbour slugs, it does not readily become sour, and it lasts a long time without decaying. The greater part of the plants will flourish in peat alone, and for those which will not it is an easy matter to place other soil round them at planting time. Most of the plants, however, are very accommodating, and can be grown perfectly well without peat; but it is absolutely necessary to have the border rather light, and it is advisable to have it a little above the ordinary level, for many more plants die from damp and sour soil than are killed by frost. The best time for planting (a very few plants excepted) is October and the beginning of November, whether the plants are old established ones to be divided, or are bought from the nursery in pots, they then make a few roots before winter without growing visibly at the top. Many plants supposed to be rather tender will, if shifted at that time, bear the winter better than if left alone. The reason is they just receive a sufficient check to prevent them making late growth which they cannot mature. The strictly herbaceous plants—i.e., those which die back to the ground after flowering, if at all tender should not have their stems cut down till the spring; the dead flowers should merely be cut off the tops.

I am only a beginner with this class of plants. I think this is my fourth year, but I have already a beautiful selection; two-thirds of them have still to flower, and some new arrivals are not sufficiently strong to flower at all this season; nevertheless, the appended list, every plant of which was actually flowering on the 3rd of August, is a very interesting one, and

I challenge any person to find a single plant named therein which is not worth growing.

I cannot finish these notes without recording how much I owe to my dear departed old friend George Wheeler, who made this class of plants a speciality for the greater part of his life, carefully saving many a good thing which would otherwise have been lost to Europe. Would that he had lived to see the great objects of his attention again become popular; but he has done his work well, he has saved them for us, and there is now no immediate danger of losing them. He, however, leaves a great void; Warminster is not Warminster to gardeners without him. We could a short time back call in and chat, as it were, with a bygone age, and feel quite sure that everything he told us was as perfectly true as if we had seen it ourselves. Old age had not made him childish, and his memory was remarkable; he would name almost any old-fashioned plant at sight and tell some interesting tale about it into the bargain. Only a few months ago, too, he told me how he walked home from Bowood to Warminster for his Christmas dinner in 1813, remarking that it had been mild weather to that time, but that he had to go back through a deep snow, and that very severe weather followed.

Hardy perennials in flower August 3rd:—

<i>Achillea ageratoides</i>	<i>Lilium tigrinum</i>

—WILLIAM TAYLOR.

THE DUKE OF BUCCLEUCH GRAPE.

I AM sorry that I was unable to be at the last Committee meeting of the Royal Horticultural Society at South Kensington, for then I should have had the great pleasure of seeing the above noble Grape well done by. It is years since I first saw and tasted it at the Kelso Show, and I have never ceased to think well of it. I have four young Vines now planted; one has two small bunches which are ripening now, though the cane was only put in this year. My own opinion is that it will make a good outdoor wall Grape in the south, and I have given a friend of mine a plant to try it under these conditions. I find it does not like artificial heat. It was very well shown at both Tunbridge Wells and Tunbridge Flower Shows by Mr. Johnston of the Gardens at Bayham, the beautiful seat of the Marquis of Camden, where I had the pleasure of seeing the Vine in excellent growth. It has been planted three years; the rod is about 14 to 16 feet long, and there has been a crop of

thirteen large bunches, though there are but three left. I found the berries larger than any others in the same house, though Mr. Johnston's Muscats were very fine, as indeed were all the other sorts, and I have seldom seen houses in better trim. The flavour was delicious, though with no stones as far as I could find. I hoped to have tasted it again at lunch, to which some of the bunches were sent, but it appeared to be so much a favourite that I lost the chance, and I had some of the Auvergne Frontignan, which were excellent and rich though rather small. I am still of the same mind as regards the Duke, and that is that it is a noble fine-flavoured Grape and well worthy of a little trouble, and certainly of a trial. The Madresfield Court, I was told, cracks in the Bayham vineries, as also with other growers about here and also with me. If it does this year I shall graft another kind on it. My Muscat Champion and Venn's Muscat both continue to give me entire satisfaction.—HARRISON WEIR.

FRAGRANT ROSES.

ONCE Mr. Hinton asked for a return of fragrant Roses at the yearly election of Roses which he is good enough to take. He met with a poor response, Mr. Curtis, I believe, being the only person who gave any good return; but he certainly made up for the shortcomings of others by sending in a most elaborate return, classifying the various scents, and giving a really valuable essay upon Rose fragrance. I do not pretend for one moment to be able to do this, but I have lately taken a great deal of trouble and spent many days at the nursery of Mr. Walters at Exeter in investigating the fragrance of the leading varieties of Roses. I had a double object in doing this. I was anxious not only to send you a report, but for my own private reasons I wished to find out the most fragrant Roses. I have a friend and neighbour who is blind, and throughout the Rose season I try to send her the most lovely Roses I can find, but above all others the most fragrant.

I went four mornings and four evenings to the nursery I have named, and went carefully through the lines on each occasion and noted down my opinions, which are given to your readers for what they are worth. Perhaps some may not agree with me in some cases, and others may supplement the list. I had not the opportunity of investigating many of the newer varieties, as my friend prefers to know something about a new Rose before he buys it.

Of all Roses I unhesitatingly place La France first as the most fragrant Rose in existence. There is something also quite distinct about this Rose which makes it particularly agreeable. I have lately had to visit a little girl who has been ill for a quarter of a year, and each time I have taken her a basket of Roses. She would take out the blooms one by one and inhale their perfumes, but she never made any remark, except about their beauty, till she came to La France, when on each occasion she said, "How sweet!" Charles Lefebvre comes next in sweetness, and Madame Victor Verdier is equally good. Abel Grand has quite another kind of fragrance which is particularly grateful. Marie Baumann, besides being one of the most beautiful, is also one of the sweetest Roses. Lord Macaulay also is a very fragrant Rose, and Duke of Wellington and Xavier Olibo. Dr. Andry also can claim to be a good all-rounder, having form, colour, healthy growth, and fragrance. The Victor Verdier race are deficient in fragrance. To this family belong Comtesse d'Oxford, Président Thiers, Eugénie Verdier, Marie Finger, and Hippolyte Jamain. Of the very dark Roses Pierre Notting is exceedingly fragrant; and Auguste Neumann, Camille de Rohan, Louis Van Houtte, and Reynolds Hole are all very good in this respect. It is a little difficult to go on through the catalogue and name all the most fragrant, but I am confident that those I have named, besides being the *crème de la crème* of Roses, are also most fragrant. Of the light Roses Madame Knorr is very sweet.

We now come to Teas and Noisettes, and of this lovely family it will be hard to select any which are not fragrant. The most fragrant of all in my opinion is one which I am very fond of—Madame Bravy or Madame Sertot. Some people think this is the same Rose as Alba Rosea, or as Mr. Mitchell of Pittdown has it, Joséphine Malton, but they are, though near relatives, quite distinct. Madame Bravy curls her locks to the very crown of her lovely head, Alba Rosea is content with merely curling the lower part of her head; but both are of equal excellence when fragrance is concerned. Next to this I place another of my favourites, Catherine Mermet. Her fragrance partakes somewhat of ripe fruit, such as Apples, but

hers is a most distinct perfume. Then next for fragrance is the old favourite climber Lamarque. This has a pure lemon scent, quite distinct from all others. The pure Tea scent I should give to Maréchal Niel and Souvenir d'un Ami. Gloire de Dijon also possesses this fragrance, and her numerous family possess the same distinguishing mark. Cloth of Gold is also fragrant, and Solfaterre and Devoniensis are both good in this respect. I could go on through the whole family and find something to say of their fragrance, but your space will not admit of more on this subject just at the present.

Before concluding I wish to notice one thing. I was quite startled with the beauty of two of Mr. George Paul's children, I mean Roses—viz., Reynolds Hole and Sultan of Zanzibar. The former, of course, is well known, but I doubt if it has ever been so fine as this season. I went again and again to see blooms of this Rose at Mount Radford. Sultan of Zanzibar is a very great acquisition. It is an immense gain to the velvety dark varieties. It appears to be a very good grower on the maiden and also on the cut-backs, and it is infinitely superior to either Prince Camille de Rohan or Louis Van Houtte, taking the average of blooms from these varieties.

One or two of Mr. Charles Turner's seedlings have much pleased me, particularly Penelope Mayo. Emily Laxton, another seedling sent out by the Cheshunt firm, is also a very good Rose. It is rather like Monsieur Noman, but with greater strength to endure wet, and a later bloomer.

Of comparatively new French Roses I was highly delighted with Souvenir de Louis Van Houtte, which is quite as dark as his namesake, and large and of good form. Duchesse de Chartres is also a fine dark Rose, but a little wanting in substance, the form somewhat like Prince Camille de Rohan when in bud. I formed a very good opinion of Earl of Beaconsfield, which was raised by Captain Christy, and is to be sent out by Mr. George Paul. Of the French Roses of this year I know nothing personally, but am assured by very good judges that there is nothing worthy of notice; but of course it is early to judge of them yet.

The more I live the more am I convinced that the prizes come from English and not from French growers. Hardly a year elapses but Mr. Turner and both the Waltham Cross and Cheshunt firms give us Roses which are not only good at the time sent out, but also improve on acquaintance. And in this matter, as in all others, I cannot but echo the remark of the British tar who, when listening to a fervid description of the delights of another world, replied, "It is all very well, sir, but old England for me."—WYLD SAVAGE.

THE FRUIT CROP.

NEVER was the uncertainty of our climate more strongly exemplified than during the present year. From all parts of the country glowing reports of the prospects of a heavy fruit crop came to hand. We, however, were congratulating ourselves too soon it proved, as soon after the next thing to be heard was the mysterious wholesale and very general disappearance of the young fruit. Various reasons, according to local circumstances, are given as to the cause of this disappearance. The solution offered by Mr. Thomson (page 465) does not, I think, fully meet the case, although no doubt in his case materially contributing towards the failure—viz., as being another striking illustration of the importance of well-ripened wood in autumn. "AMATEUR" is, I think, much nearer the true solution when he says (page 449), "The cause of failure was the continued rains, the sodden state of the soil, and the absence of sun." This is fully corroborated from what I have seen and heard both in this county (Essex) and Shropshire, two counties widely dissimilar yet in one respect analogous. Both with few exceptions have a moderate rainfall, this part of Essex in particular. In both instances well-ripened growth of the best description, calculated to produce an abundance of healthy well-formed bloom, was made. This with a few exceptions was the case, and we and others were justified in anticipating an abundant crop, more especially as there had been light crops the two preceding years. In Shropshire on the whole they have, and have had, a fair average crop, the only exception apparently being Apples. This is not the case, however, in this neighbourhood, as in the orchards the common varieties of Plums only are bearing heavy crops. This difference I ascribe to the totally different character of the country and nature of soil. Both counties experienced similar dull, wet, and cold weather after blooming time; we, unfortunately being in a very flat district, the soil rich and

heavy resting on a cold and imperfectly drained subsoil in every respect different to Shropshire, got much the worst of it. The more elevated the garden the better the crops this season, and this, of course, tends to prove "AMATEUR'S" theory the correct one. For the sake of comparison and the benefit of intending planters I append a list of the most prolific varieties of fruit personally obtained in both counties and also communicated by friends, taking Shropshire first.

Apples are below the average; the varieties bearing heavy crops are Keswick and Manks Codlins, Early Hawthornden, Besspool, Cox's Pomona, Sturmer Pippin, Scarlet Nonpareil, Wyken Pippin, Golden Noble, and Northern Greening. The following are carrying average crops—Ladyton Codlin, Lord Suffield, Court-pendu-Plat, Golden Reinette, Orange Pearmain, Nectarine Apple, Fearn's Pippin, Dumelow's Seedling, and Bedfordshire Foundling.

Pears both on walls and as standards are a fair average crop. Pyramids on the Quince stock are also bearing well; those on the Pear stock, on the other hand, are carrying very small crops, and the fruit apparently of a very inferior description. The following are the most prolific both on walls and in the open—Williams' Bon Chrétien, Louise Bonne of Jersey, Glou Morceau, Joséphine de Malines, Easter Beurré, Beurré d'Amanlis, Brown Beurré, Beurré de Capiaumont, Beurré Rance, Ne Plus Meuris, Winter Nelis, Seckle, Marie Louise, Chaumontel, Uvedale's St. Germain, and Beurré Diel.

Plums are bearing a heavy crop, especially the following—Angelina Burdett, Coe's Golden Drop, Diamond, Green Gage, Transparent Gage, Reine Claude de Bavay, Orleans, Jefferson, Ickworth Impératrice, Washington, Magnum Bonum red and white, Prince Englebert, Victoria, Kirke's, and Pond's Seedling. Damsons are a very heavy crop, and the trees are as plentiful in the hedgerows and small gardens as Apple trees are in Herefordshire. The fruit is usually bought up and sent to Manchester and is there used in the manufacture of a dye. There is also a fair crop of bullaces.

Peaches gave promise of being a heavy crop, but many fruits dropped. The trees, however, are still bearing a fair average crop. The Noblesse, Royal George, and a variety known as Neal's Purple are the best. I have seen this variety doing well in two different gardens, where it is considered the best variety grown, as it is very robust and fruitful and the quality excellent. Nectarines are also a fair crop, Elruge and Violette Hâtive being the best. Apricots are an average crop, Hemskirk and Moor Park carrying good crops of nice clean fruit.

Gooseberries where protected from the bullfinches bore well, also Red and Black Currants, especially the latter.

Raspberries were very prolific and Strawberries remarkably so, some old growers being of the opinion that they had never previously seen such heavy crops of fine well-flavoured fruit. All the following varieties were grown—Keens' Seedling, Sir J. Paxton, President, Sir C. Napier, Dr. Hogg, British Queen, and Elton Pine. Figs are plentiful, and also Filberts. Walnuts are below the average. Cherries of all sorts were very fruitful, the Morellos remarkably so.

In this neighbourhood the Cherry orchards at blooming time were a sheet of bloom, but the old trees produced so little fruit that it was found inadvisable to go to the expense of keeping the birds off. Bigarreus, Elton, and Morellos on the walls, and Flemish, Kentish, and Morello as standards, bore very fair crops, especially the latter. Apples generally are a very poor crop, the few exceptions being New Hawthornden, Keswick and Manks Codlins. Lord Suffield, Dumelow's Seedling, Blenheim Orange, Golden Reinette, Old Nonpareil, Northern Greening, Scarlet Pearmain, Golden Noble, Norfolk Beefing, Devonshire Quarrenden, and Winter Codlin. Pears also are rather scarce, especially on the walls. Williams' Bon Chrétien, Duchesse d'Angoulême, Ne Plus Meuris, Beurré Diel, Beurré de Capiaumont, Beurré d'Amanlis, Bishop's Thumb, Winter Crasanne, Marie Louise, Swan's Egg, Vicar of Winkfield, and Bergamot Esperen are carrying fair crops, especially the first mentioned. Peaches are bearing a very good crop, notably Royal George, Padley's Seedling, Grosse Mignonne, and Bellegarde. The same remark applies to the Elruge, Hunt's Tawny, and Violette Hâtive Nectarines. Plums on the whole are carrying a very light crop, the exceptions being the Orleans, Mitchellson's, Pond's Seedling, Prince of Wales, Green and Transparent Gages, Magnum Bonum white, Early Prolific, Coe's Golden Drop, and Victoria. Some trees of the latter variety are carrying very heavy crops, one grower thinning out and sending to a merchant for bottling one ton of fruit. A very

remunerative price was obtained, and the value of the crop will be enhanced by the judicious thinning. Damsons are rather scarce, and also the Winesours. Gooseberries were a complete failure. This was caused by the frosts experienced after the fruit was set. Black Currants bore a very heavy crop, the Red a very moderate one. The same remark applies to Raspberries, the dry weather during June and July being very much against them. The Strawberry crop—and there are many acres devoted to them in this locality—was much below the average. The quantity and quality of bloom was good, but the wet dull weather was very injurious to the early varieties, and the extremely dry and hot weather experienced later on was equally bad for the late ones. Quinces are rather scarce, and have been for three consecutive seasons. Filberts are fairly prolific, especially where the precaution had been taken of shaking branches of the common Hazel bearing catkins among them at blooming time. Figs and Walnuts are bearing a thin crop, and the Mulberries are lighter crops than usual. Blight of every description seems very prevalent on nearly all kinds of fruit trees this season, Plums and Apples suffering the most.

The American blight, hitherto almost unknown, is very bad in this district; but the late thunderstorms have greatly improved the appearance of the trees, cleaning by hand being out of the question. Birds, too, seem to be unusually destructive, fruit of all descriptions being attacked before it is half ripe. The small birds are the most troublesome.—W. IGGULDEN, *Orsett Hall*.

SHOW PELARGONIUMS.—No. 1.

FOR a few years after Zonal varieties increased so rapidly, and when so many superior sorts were distributed, Show Pelargoniums appeared to be in some measure neglected. Flowers, however, so beautiful as these are could not long remain in any sort of obscurity, and more attention is now being devoted to them than was the case a few years ago. This section of Pelargoniums cannot with any justice and fairness be placed in comparison with Zonals. The two types are so thoroughly distinct that the merits of each must be judged separately. Zonals are valuable for their continuous-blooming properties, their fine trusses, varied colours, and easiness of culture. Show varieties, on the contrary, have a limited season of beauty, somewhat short it may be, yet long enough, and for the time incomparable. Their bold yet refined flowers, with their unique colours arranged in the most correct and artistic manner, are simply unapproached by flowers of any other section of this great and important genus of plants. The Show varieties, too, are of easy culture, yet require more care in their general treatment than do the Zonals. The latter if neglected occasionally do not show the effects of it so markedly as the former; but then, on the other hand, the Show varieties give a splendid return for any special attention that is accorded to them, and always when well grown reflect credit on the cultivator.

These beautiful flowers are alluded to now because the present time is about the best period of the year for purchasing plants. A much better plant of established varieties can usually be obtained at this season for the money than is disposable in early spring. In the spring young plants only can be expected that will produce at the most only a truss or two of bloom the same season; but a stout plant obtained now will, if well grown, make a decided display the first time it flowers with its new owner. Plants sent from a nursery now will not have an attractive appearance. If they have not been cut down they will resemble a bundle of semi-dried sticks, while if they have been pruned they consist of so many leafless stumps. They will, however, not long remain in this state, but will improve daily. Those who prefer having plants in free growth and thoroughly established after being cut down will defer their purchases until September or October; indeed, it is better to do so than to order plants when they are just breaking into growth, as in this state they are susceptible of injury during transit. Still, nurseriesmen are admirable packers, and generally ensure the safe and sound arrival of their consignments.

If the plants arrive with their summer growth intact they must be cut down at once quite closely, leaving only an eye or two of the wood made during the current season of growth. If they are already cut down they must remain for a time in the soil and pots in which they arrive, being watered moderately until they have made fresh growth from half an inch to an inch in length, this growth being made in the open air.

The plants must then be shaken out of the pots, most or all of the old soil being removed, and the fibrous roots, which will be "dead or dying," be cut off with a sharp knife, the plants being potted in smaller pots than before, placed in a frame, watered, kept close for a week, and slightly shaded if need be, and new roots will speedily be emitted, and the plants will commence growing vigorously, and will more than make up for the little lost time incurred by the slight check attendant on the cutting-down and disrooting process.

A short time ago a correspondent questioned the soundness of what he termed the desiccating and disrooting practice; he had tried the system and lost many plants. No doubt the practice of drying the growths of *Pelargoniums* can be carried to extremes, and the work of cutting down and repotting can be wrongly conducted; and it is certain that there is something wrong in the treatment and manipulation given if many of the plants die under the operation. On a moderate calculation the writer has assisted in cutting down and potting quite a hundred plants a year for the past thirty years, and certainly not one per cent. of the plants so treated has failed to flourish satisfactorily, notwithstanding that the disrooting was done in a very thorough manner.

There is a difference between maturing the growths of *Pelargoniums* and desiccating the plants. If a plant immediately it has ceased flowering is placed outdoors in the full sun, and water is suddenly and entirely withheld, and the foliage is permitted to be burnt up and shrivelled in a week, while at the same time the flower trusses are allowed to remain and seed form, as it will do under such circumstances, the growth of that plant is indeed desiccated but not matured, and we have no right to expect it to prosper. But if, on the other hand, the flower trusses are removed as the flowers fade, insects are kept from infesting the foliage, water is intelligently given in graduated supplies so as to sustain the foliage fresh for a reasonable time, yet to permit its gradual change to its early advancing autumn rest, the stems will store up abundant nutriment for the nurture of the forthcoming new growths until such time that fresh roots are formed to appropriate the fresh food supply given in potting to carry on the plant to maturity.

Now to disrooting. That has also been questioned. Disrooting as recommended under the above circumstances is an absolute gain to the plants—first, because the new roots issuing are far more vigorous than the old fibres; and secondly, because the restricting of the roots in bulk affords space for storing a much greater amount of food for the plant than would otherwise be the case unless pots of unwieldy size were employed, and in which the plants, while they might grow freely, would not grow compactly nor flower profusely. Thus ripening of the wood of the plants, cutting them down and greatly disrooting them, are necessities of culture, but those operations must be intelligently performed. The cutting-down and potting must not be done simultaneously, for the old roots are necessary to give a start to the new growth, and then new roots are equally necessary to sustain it.

All plants of Show *Pelargoniums* that have been cut down and have made some fresh growth should be disrooted freely and be repotted in clean well-drained pots. It is often well to wash the roots clean, and while wet to dash them with silver sand when the plants are being potted; new roots are then emitted from the old speedily, and the plants grow freely and healthily.—A NORTHERN GARDENER.

ODONTOGLOSSUM LINDENI.

IN your notice of the exhibits at the Royal Horticultural Society's meeting on the 6th inst. you allude to *Odontoglossum Lindenii* being exhibited by Mr. Buchanan, your reporter having incorrectly copied my name.

As to my gardener belongs the credit of having first flowered this plant in England, I will, for the information of your readers who may have a similar plant in their collections, state it was purchased by me about six years ago at Messrs. Stevens', and was kept in a temperature the same as *Cattleyas* and *Vandas* for about four years. Finding it did not flower, I had it placed two years ago with the *Oncidiums* and *Odontoglossums* and subjected to a very low temperature, my house not exceeding 55° all last winter, and since the early part of May no fire heat whatever has been used. I think this proves *O. Lindenii* to be a specially cool Orchid, and I make no doubt if similarly treated other plants might annually throw flower spikes. Its flowers are of a cinnamon colour, and they will

remain more than two months in perfection.—H. J. BUCHAN, *Wilton House, Southampton.*

AN AMATEUR'S VINERY.

MR. WITHERSPOON'S, CHESTER-LE-STREET.

WHEN an accomplished Grape-grower like Mr. Johnston of Glamis Castle states that a vinery is "worth going a thousand miles to see," that is sufficient testimony of its being worthy of notice in these pages. It was in company with Mr. Johnston, and Mr. Hunter of Lambton that I had the privilege of inspecting Mr. Witherspoon's Grapes at Chester-le-Street when the above verdict was given. Mr. Hunter is, of course, equally impressed with the excellency of the Grapes, but for a reason sufficiently obvious he is not in a position to express himself so freely as his *confrère*. It is in a great degree Mr. Hunter's success as a grower of Grapes that encouraged Mr. Witherspoon to commence their culture, and now that the Chester-le-Street amateur has succeeded so well he does not hesitate to acknowledge the value of the advice given by his Lambton friend, and not advice only, but substantial assistance.

Mr. Witherspoon is in the strict sense of the word an amateur. Throughout a long period of life as a practical builder he has devoted his spare hours to the pursuit of gardening, to which he was attached from boyhood, and now he is in a position, achieved by industry and frugality, to have a garden of his own, and to spend his whole time in developing its resources. He has taken up the special culture of flower after flower, ending with *Roses* and *Gladioluses*; and with the last-named flower has won high honours, not at local shows only, but at some of the chief exhibitions in England and Ireland. Fruit culture has, however, supplanted the flowers, few of which remain except *Roses*, and *Roses* and *Vines* now give a title to his home, which is designated the "Red Rose Vineries."

Chester-le-Street is a long straggling village, venerable in appearance, and having a bold ruggedness, which renders it in some degree picturesque. The houses were built, or most of them, before Boards of Works were invented, and no arbitrary rules as to frontages interfered with the growth of a gable end where it happened to spring up a few feet higher than its neighbour or several yards out of line; indeed, lines, levels, and laws of uniformity appear to have been systematically ignored in the architecture of this quaint place, for quaint it appears when viewed from the railway station above it, for the houses are clustered in a valley, along the bottom of which an open stream threads its tortuous course. At the opposite end of the village, about a mile from the station, we find a place of more modern aspect—the Red Rose Vineries.

The district is one of meadows and pasture lands, the fields being almost wholly devoted to the growing of fodder for the great numbers of horses which live and labour in the coal seams below the surface. The soil, which has this year produced wonderful hay crops, is a brownish loam, rather heavy but not clayey, and generally rests on a substratum of sand—at least that is its character in the field purchased by Mr. Witherspoon for the growing of Grapes, Peaches, &c., under glass, and hardy fruits in the open air. The position is also sheltered, being in a valley, and the atmosphere appears clear, there being no outlets in the immediate locality from the mines below. Thus both soil and position are peculiarly favourable for Grape culture, and another important local advantage bearing directly on the subject is that coals are cheap.

In the trenching of the ground for hardy fruit trees and vegetables the top spit of the pasture was reserved for the Vine borders. Of this fertile turfy loam the borders consist without any admixture except a few stones and lime rubbish in one house, and resting on sand perhaps no artificial drainage was required. The only other necessary was water, which Mr. Witherspoon, like Mr. Hunter, uses in large quantities, not to the foliage, but to the roots of the Vines. The water employed is rain water, which is conveyed from the surrounding hills and stored in a large cemented open cistern at a point in the garden sufficiently high to afford the requisite pressure for drenching the borders, and if need be the Vines too, through metal pipes and hose. The system of water-storing is precisely the same as that adopted by Mr. Cannell in his nursery at Swanley. Another matter reminding of Swanley is that Cannell's boiler is employed as the heating medium for the vineries.

Two houses are devoted to Grape culture, but only one demands special notice—the large lean-to house, 150 feet long

with a 23 feet length of rafter. The Vines were planted in March, 1876, and the crop now hanging is altogether splendid. The permanent Vines trained up the roof were planted 2 feet 8 inches apart. They have made wonderful growth and quite cover the roof, save a few feet left for the advantage of the fruit on the back wall, but are only cropped about one-third of the way up. Each Vine is carrying from six to twelve bunches, which for size, shape, and regularity of berries are worthy, at least a hundred of them are, of being staged at any exhibition of Grapes in the kingdom, while not one inferior bunch is to be seen in the vinery. It is not so much a few fine bunches as the high average excellence of the whole that impresses on the minds of visitors the superiority of the crop. The lower part of this fine roof, covered from end to end with noble bunches, is nothing less than a grand sight; but not less striking is the crop on the back wall. This wall is 14 feet high, forty Vines are planted at its base, and the whole wall is covered from top to bottom with bunches that would be a credit to any man if they were hanging from the roof. Knowing that when the roof is covered densely the Vines on the back wall will deteriorate, their owner is acting accordingly by cropping the wall Vines heavily; and those on the roof what many would call heavily too, but, considering their great vigour and extensive terminal growth, lightly. Such is the crop on the back wall and the character of the bunches, that there can be little doubt in one year the commercial value of the Grapes will equal the entire cost of the structure. As an instance of the crop on the wall let us take one Vine of Dr. Hogg, carrying seventeen bunches, which will certainly average $2\frac{1}{2}$ lbs. in weight, or upwards of 40 lbs. on one Vine. Another "nursing" Vine of Black Alicante has still a much heavier crop, having twenty-nine splendid bunches; but this is one of six Vines planted at intervals along the centre of the house, and trained with two rods to the top. The total number of Vines in the house is ninety-nine. Almost all the popular varieties of Grapes are trained both to the roof and the back wall, the best for the last-named position being, in Mr. Witherspoon's opinion, Black Alicante, the vigour of this Vine and its free-cropping and good-colouring qualities being its recommendations for such a position.

Gros Colman both on the wall and the roof is bearing noble bunches freely, the berries measuring $3\frac{1}{2}$ to $3\frac{3}{8}$ inches round. Some of the bunches will weigh from 4 to 5 lbs. Dr. Hogg on the roof has seven bunches 15 to 19 inches long, and berries $1\frac{1}{2}$ inch in circumference before showing colour. Golden Champion on the wall has six bunches, which will weigh from 3 to $3\frac{1}{2}$ lbs. each, the berries being fine and clear. This Vine happens to be in the most moist position in the house—near the tank, and it is to that circumstance that its satisfactory condition is attributed. Black Prince is bearing handsome bunches 13 inches long, and Syrian has three bunches weighing in the aggregate about 20 lbs. Black Alicante on the roof is in every instance splendid. Mrs. Pince very good, and Black Ham-burgh fine. Golden Queen has made a grand cane, and so has Waltham Cross, the latter bearing fine but not full bunches. The berries of this and another Vine or two near it not having set well owing to having been shaded by a large tree, which impeded the ripening of the wood last year.

The bunches in this house are not more remarkable for their size and shape than for the regularity of their berries. They have been carefully and admirably thinned. At the first glance the crop on the permanent Vines appears a heavy one, but when the system of thinning is considered the crop is not so exhaustive as it looks. Mr. Witherspoon's mode of lightening a crop is by the removal of berries from the bunches rather than cutting off the bunches themselves. The berries in the dark crowded centre of a large bunch cannot, he assumes, be of such high quality as those exposed to light and air, consequently all the interior berries are cut out, and only those are left which can have full exposure; the result is fine berries symmetrically arranged and highly finished. Great care is taken never at any time to touch the berries either with the hand or with water from the syringe, in order that they may ripen in the best condition as to bloom. The Vines are never syringed. The borders are heavily watered periodically, and are regularly sprinkled two or three times a day according to the weather, so as to prevent any dust rising; thus both Grapes and foliage are fresh and clean.

It may be stated that, anticipating the failure of the Vines that are now carrying such a remarkable crop on the back wall, Camellias are planted at intervals. The Vines will be cut away as the Camellias grow, and eventually the latter will cover the wall. Although comparatively slow-growing shrubs

Camellias are specially suitable for the back walls of vineries, and eventually are about the most satisfactory and profitable plants that can be grown in such positions. The Vines on the wall will produce valuable crops for two or three years longer, and by that time the Camellias, now well established, will have covered much space. It is not difficult to cover the back walls of vineries in a profitable manner, provided the same plan is adopted as above described—that is, by planting for covering the wall the moment the roof is glazed and the border made; but on the contrary, if the roof is first allowed to be covered, then it is a most difficult matter to furnish the darkened back wall satisfactorily.

The other vinery is a small structure, and was planted in July last with Vines presented by Mr. Hunter, and a good crop is now ripe. They demand no further notice, but a plan for protecting the Grapes from nocturnal visitors may be alluded to. It is rather novel. Stout wires are affixed to the back walls of the vinery at both ends of the house; the wires are taken along the front near the outer edge of the Vine border, where they lie on the ground. Every night two savage dogs are looped to the wires by rings in their collars, and these two sentinels traverse the wires from end to end, so that it is impossible for anyone to approach the Grapes without Mr. Witherspoon being apprised of the fact, his residence being close to the vinery.

Besides the above vineries Mr. Witherspoon has erected a Peach house and vinery combined. This structure is 200 feet long, has a great length of rafter facing south, and a short roof admitting light to the back wall from the north. Vines have been planted along the front this spring and are making excellent growth; Peaches being planted and trained to the back wall, and are also thriving in the best manner. The varieties are Royal George, Condor, Magdala, Goshawk, Large Early Mignonne, and Merlin. They were selected by Mr. Rivers, and were obtained from, as indeed most of them were raised at, Sawbridgeworth. The purchased Vines, which are doing so well in the house first referred to, were chiefly procured from Mr. W. Thomson of the Tweed Vineyard, Galashiels. Mr. Witherspoon also grows several fruit trees in tubs, and grows them well—Peaches, Nectarines, Plums, Apples, Pears, Figs, and Mulberries—as those for which he obtained a special prize at the late Newcastle Show bear witness.

The "field" outside, as Mrs. Witherspoon will persist in calling it, but in reality a highly cultivated garden, will eventually be a garden of fruit. Bush and pyramid trees of the best sorts have been planted liberally, and will in time occupy almost the whole space. At present much of the ground is cropped with vegetables, of which the owner prides himself in having carefully selected strains. Certainly the bed of Red Cabbages both for dwarf growth and high colour is an excellent one, the plants being true, even, and very fine.

It should be mentioned that Mr. Witherspoon has himself made and erected the extensive glazed structures, which are light, plain, durable, and well ventilated. But the work was not done without an obstacle. A tornado during the progress of the work lifted off half of the vinery roof after it was glazed and smashed a ton and a half of glass—a valuable hint, the owner coolly observed, that he must build more securely in future, and now the houses are safe. He has also erected a convenient and substantial house pleasantly situated. It overlooks the picturesque valley of the Wear, has a full view of Lumley Castle in the immediate foreground, and the woods of Lambton crest the distant hills.

It is a real pleasure to visit the home of one who has worked to such a good purpose and succeeded so well, and one who has taught as well as worked. The owner of the Red Rose Vineries has occasionally enriched the pages of this Journal, and his writings on horticulture generally, and on fruit and Grape culture particularly, must in future be accepted as those of one who has done more than he is ever likely to tell, yet one whose works entitle him to be listened to with that confidence which success inspires.—J. WRIGHT.

EUCALYPTUS GLOBULUS AT MUCKROSS.

It is truly encouraging to notice how this tree thrives at Muckross Abbey. The progress it has made since my last remarks in the columns of this Journal is most satisfactory. We have some fine specimens of the above, and it may interest some of your numerous readers to give the dimensions of it. One specimen, a very fine plant, has attained the height of 45 feet; girth 1 foot from the ground, $26\frac{1}{2}$ inches; at 3 feet

high the girth is 25 inches. This tree wears the most flourishing appearance at present.

On a former occasion I gave my opinion of the manner in which it should be sown—viz., to sow the seed where the plant is intended to remain, as the tendency of the Eucalyptus is to send down a strong tap root, which is the main support of the plant afterwards. If raised in pots the tap root assumes a spiral attitude, which it retains, and is therefore liable to be disturbed by every breeze and ultimately upset, whereas if sown where intended to remain the roots naturally assume their proper shape and direction for the future stay and support of the plant. Seeds of the above sown here on June 9th, 1876, in patches in the open ground have made rapid progress. I have treated them thus: As soon as the plants attained the height of 9 inches I removed all but the most promising, which are now 14 feet high and of the most perfect form and healthy appearance. In my opinion also the side shoots of the Eucalyptus require when young constant stopping as a young Fuchsia, which has the effect of strengthening the plant and giving it ability to stand unsupported.—A. CAMPBELL, *Muckross Gardens*.

THE TRANSFUSION OF ESSENCES.

We have had many instances of what may be called the transfusion of the essences of plants; one of these is familiar to everyone in *Cytisus Adami*, and we some years ago furnished another, where the essence of Doyenné Defais Pear was so transfused by the pollen into a tree of Beurré Superfin that the fruit of the latter actually produced fruit of Doyenné Defais, which we ourselves saw. The case which has now come under our observation is that of the Madresfield Court Vine, the essence of which has been transfused by grafting (as in the case of *Cytisus Adami*) into a plant of the Vine called Sarbelle Frontignan. The former produces a large handsome Grape and the latter a small and insignificant one; yet, through the operation of grafting, the essence and individuality of the former have so perfectly passed into the latter that it has produced a fine bunch of Madresfield Court fruit, which is now lying before us. We cannot do better than to print the communication which our esteemed correspondent Mr. Barrell has sent us:—

"A freak of Nature (if that be the proper term for such a case) has occurred in my vinery, which I am told by some eminent horticulturists is so remarkable that I send you a description. About eight years ago I planted three houses, each 20 feet square, with several varieties of Grapes. One of them, which has been appropriated as a stove, was planted with Muscat of Alexandria and Muscat Hamburg. The next year one of the Muscat of Alexandria failed, and I replaced it by one of which at that time I knew nothing—viz., Muscat Sarbelle. This I have fruited for the last four years, and have found it as Dr. Hogg describes in his 'Fruit Manual,' 'hardly worth a vinery,' and therefore last year I inarched Madresfield Court upon it from a Vine in a pot. The scion duly united and was cut from its parent, after which it continued to grow for some time. At the usual time of dressing and pruning I was about to cut back the stock to the inarch, when it (the inarch) came completely off, leaving not a trace behind. I told my gardener to leave the stock alone after that, as a few bunches of Muscat Sarbelle would be better than a blank space, and we would again inarch or graft it this year. Can you judge of my surprise at finding that the fruit the old cane of Muscat Sarbelle has brought forth very closely resembles the Madresfield Court, and is certainly as unlike the former Muscat Sarbelle as it well could be?"

"I send you (by rail, carriage paid) the last bunch I have that you may see it for yourself, and although it is much smaller and in worse condition than the others, it will be sufficient to demonstrate the curious sport. I regret that I did not think of it sooner so that you might have had a perfect bunch. I have left a lateral this year below the place of inarching, which I purpose fruiting next year to see if the same influence has in any degree been transmitted downwards as well as upwards."

The fruit sent is certainly that of Madresfield Court, rich in flavour, and with a more decided flavour of the Frontignan than is found in the normal form.

This is another instance which confirms our observations made at Culford Hall, and which have been so much discussed and questioned, and we can relate others. The following, observed at Dr. Newington's, are cases where the scion has exercised an influence on the stock.

The tip of a shoot of a Madresfield Court Vine was grafted on a shoot of Black Hamburg, and produced at 6 feet below the junction a bunch of Grapes having the round berries of

Black Hamburg, the normal form of the Madresfield Court being oval.

A Madresfield Court Vine had a White Muscadine grafted on it, and then it produced round Grapes; but when the Muscadine was removed it recovered its normal form and produced oval Grapes.—H.

GEUM COCCINEUM FLORE-PLENO.

A CORRESPONDENT, "L. L. D.," quoting the remarks relative to this plant which appear on page 398, vol. xxxiv.—namely, that it is one of the "earliest, brightest, and finest" of hardy border plants, adds that it is not only early but late, because it flowers with him continuously from early spring to late summer. He sends us flowers, such as he is in the habit of cutting for decorative purposes throughout the season, and

Fig. 18.—*Geum coccineum flore-pleno*.

urges the advisability of others having a similar supply. The flowers are well represented in the accompanying engraving, and it is only necessary to add that they are a brilliant deep scarlet in colour. The plants, we are informed, which flower so profusely are raised from seed, which is sown at the same time and in the same manner as Sweet William seed, and the plants have the same treatment as Sweet Williams. A bed of this fine old semi-double *Geum* should be in every garden where a supply of scarlet flowers is required for vase decoration. Young plants produce finer flowers and produce them more continuously than old plants, and hence it is advisable to sow a little seed annually so as to ensure a stock of vigorous plants. Plants raised from seed sown now would in all probability yield some flowers next year, and would certainly produce an abundant supply the year following. It is a border flower of the first order of merit, but to see it to the best advantage it should be grown in large masses.

OUR BORDER FLOWERS—POLEMONIUMS.

WERE I intending to form a collection of hardy herbaceous-foliaged plants I should most certainly turn my attention to

the Polemonium probably better known by the more homely name of "Jacob's Ladder." Why plants possessed of such merits for border and other decorative purposes are so neglected I am at a loss to conceive. We do occasionally see what is said to be a native of our land, but I entertain a doubt as to its citizenship. I allude to Polemonium cæruleum. It is a handsome spring and summer border flower, is of charming habit, having somewhat the appearance of a Fern while in a young state. It is also known by the name of Greek Valerian.

Polemoniums perpetuate themselves by seed, often becoming as troublesome as weeds. The seed may be sown as soon as ripe, or in the spring, in light soil on a rather sheltered border, or where they are intended to remain, and be thinned out as they require. They need a good space to develop themselves, for when left too thick they sometimes damp off. They are also increased by division in the autumn or spring, which is much the best mode when any variety is intended to be retained.

The variegated form is one of the most useful as well as one of the handsomest of hardy plants we possess. As an edging and ribbon-border plant for graceful appearance it cannot be surpassed. To keep the stock superior it requires constant care in keeping up a supply of young plants. When neglected they often run back to the original, especially if planted in moist situations. To have it in prime condition it should not be allowed to flower.

They are not an extensive family. Most of the varieties in cultivation have much the same habit and appearance; blue and white are the preponderating colours of their flowers. There are a few named varieties but seldom met with. They are not particular as to soil or situation provided it is not too heavy. A free loam suits them with efficient drainage.—*VERITAS.*

THE ROSE ELECTION.

I FEEL very grateful to Mr. Hinton for the friendly way in which he has met my criticisms on the subject of the Rose election.

I am so interested in all that concerns the Rose that I cannot forbear putting in my oar in every boat that is rowed; but I can assure my friend that I do not represent my own opinions only, but those of a large number of the best and largest Rose growers. If I were but to mention the remarks made at Hereford at a meeting of the best rosarians I have had the pleasure of being present at for a long time, Mr. Hinton would see that it is not the opinion of a mere Savage, but that the Wyld man was but the mouthpiece of a most influential body. Only yesterday I received a letter from one of the largest professional cultivators of the Rose saying, "I was glad to see your remarks in the Journal about the Rose election, in which I cordially concur."—*WYLD SAVAGE.*

"THE result will be what I do not hesitate to declare last year's was, 'a delusion, a mockery, and a snare.'" What, then, are we young amateurs to do? Here is "*WYLD SAVAGE*" making it out in the plainest manner that all our anxiety last autumn was in vain, that the Rose election is no better a guide to a grower for exhibition than would be a list of the Roses growing in an ordinary old-fashioned garden. I have had great delight the last two seasons in reading all that "*WYLD SAVAGE*" has said on his favourite subject; but I confess that his letter this week has quite upset me. After the election was published I quite beggared myself in order to complete my set, and now, at budding time, I am told pretty straight that I have been foiled and snared, and must I be foiled again? Is it "*WYLD SAVAGE*'s" turn to enter the ring? Is it the old game over again, the patient dying because the doctors differ? "*WYLD SAVAGE*" has driven me back to the details of the Rose election; I have chosen out seven of the best known amateurs that appear in the copies I can find, and this is the result. Out of the forty-eight Roses selected, "*D., Deal,*" names 34, Canon Hole 34, Rev. J. B. M. Camm 36, Mr. Curtis 33, Rev. E. N. Pochin 37, Rev. A. Cheales 40, and Mr. Parsons 30. I would suppose that these figures are a great tribute to the caution Mr. Hinton displayed in his selection of votes. When I compare the lists of the two champion antagonists at the National Rose Show in June last, I find that Mr. Jowitt had in his forty-eight twenty-nine Roses not in Mr. Baker's box. Fancy these two giants in their great struggle for the cup with their hundred of Roses of every kind having but nineteen in common! Yet "*WYLD SAVAGE*" says that these men, and such as they only, are to be our guide. I think he is very

severe on Mr. Hinton, and as one of the young and devoted lovers of our floral queen I could not help saying so.—*CURATE OF HOWDEN.*

RETARDING AND PREPARING FORCED FLOWERS FOR TRAVELLING.

[We cannot give a fuller and better reply to "W. T. K." and "A YOUNG GARDENER" than by citing the following on this subject.]

In following the ruling fashion of the times, and gauging the tastes of its wire-pullers, it is of some importance to keep a close watch upon the annual progress of recent innovations. We must judge for ourselves whether these are likely to pass safely through the ordeal of criticism and to establish a claim upon public attention for any length of time, or whether their recognition is not temporary, and due to some passing mania for novelty which is attracted by mere plated mediocrity, while it overlooks qualities that are of a more genuine and permanent character.

The subject before us is not an inquiry into certain fashions either retrospective or prospective; but our programme legitimately embraces the study of anticipated changes, and of schemes for working out the fulfilment of ideas that are best calculated to meet coming demands, and that are most in accord with the spirit of the times. Glancing for a moment on the past, there were signs of the foliage element taking the place of cut flowers to a considerable extent; but things have taken another turn, as the unquestionable increase in the demand for cut flowers very plainly confirms. The season wherein there is the greatest demand for cut flowers is from February to July, and there are many intervening periods which ought to be studied on individual grounds. In the first place, there is the growing of the plants and their peculiar adaptation for yielding supplies at certain times. There are individual fancies to be pleased in peculiar colours and even shades of colour, and there are certain times at which certain things are more welcome than others; but perhaps the most important thing to be studied is a proper selection of such subjects as will stand the oscillation of a luggage van without falling to pieces. It is in a way simple to grow and force flowers, but not so simple always to "hit the proper time" and transmit them to their destination in proper condition. Amongst a chain of complications there are features of varied import which, if exercised and applied with forethought, will be the redeeming features of the case; for instance, flowers that travel well should be kept in reserve for the hot weather, others of more intricate formation will answer quite as well earlier, and travel better in cold weather. All flowers can be hardened more or less gradually, and kept shaded from strong sun. The choice element—such as Orchids, Lilies of the Valley, Gardenias, Eucharis, Pancratiums, &c.—should be handled according to individual means to last over the season, so that every tray of flowers sent off shall have its fair contingent of choice things. Camellias will last from November till May. All efforts at retarding after the plants are pushing vigorously will only end in failure, therefore they should be kept as cold as is consistent with safety after the buds are set, and shading resorted to early in the season. The cooler the plants are kept the better the flowers will travel. Suppose the roof of the Camellia house is occupied with other creepers that would be injured by shade, they are a poor lot if they are not worth some special attention in the way of shade, which may be temporarily constructed inside the house and removed after the flowering season is over. Hyacinths, Tulips, Narcissus, and other bulbous plants are easily managed by rotation and hardened off according to coming demands from the warmest forcing house to the coolest frame behind a north wall. Cinerarias, Calceolarias, Prunuses, Deutzias, Spiræas, and other things may be handled in the same way, and later sowings of the two first-named may be turned out of doors altogether, and occupy similar places with little or no protection, except some slight covering, to be kept at hand in case it is required. This style of keeping your showy things out of public sight may be open to comment, but the writer never gives a pin for the critic or satirist so long as the only parties legitimately interested are satisfied. When there is any probability of a glut of Camellias or of *Maréchal Niel* or *Gloire de Dijon* Roses being caused by a sudden change of genial weather, and the flowers are situated so as to be beyond ordinary control, then numbers of other things that are more under command may be retarded in proportion by any of the means suggested elsewhere.

Rhododendrons that are forced in a high temperature had better be removed to cooler quarters before half the flower truss is expanded; indeed, for safe travelling all trusses should be despatched to their final destination before the centre flowers are open. Coming to other sections of plants that are forced under high pressure, it were better to work on some well-considered principle beforehand. If a small house can be spared which is conveniently situated in a cool aspect, with just a flow and return hot-water pipe round it that might be used in case of emergency—this house might be utilised as the centre of concentration or dépôt for receiving plants in various stages of flower from other houses. The house should have a proper shading in good working order and be well ventilated, so that the flowers could be shaded from the sun and kept cool preparatory to travelling. We are, of course, now assuming that the reader has followed our suggestions with the advancing season, and has not confounded our hints with very early forcing, in which case every bed must be open before the plant—whatever it may be—leaves the forcing house, or the sudden change will produce temporary stagnation, till the natural warmth excites a reaction.

Roses in pots, Azaleas, and all other portable subjects, either stove or greenhouse, will have their flowers greatly improved for travelling by this simple method of preparation; even stove climbers, and other large plants that cannot be carried about, may be materially assisted by lowering the temperature a few degrees, and by admitting more air during the time the plants are flowering at their best. East Indian and Mexican Orchids are none the worse of being hardened in company with other things, provided they are not exposed to draughts or sudden chills, which can be avoided with ordinary precaution; and it is no small advantage to have a spray or two of choice Orchid over as long a period as possible. I think it was Mr. Harrison of Knowsley I once heard make the shrewd remark, "You cannot finish off a box of choice flowers without a spray or two of Orchid." *Denbrobium nobile* is still the best of that large and interesting species, and is everybody's plant for cutting purposes. It stands packing better than most other Orchids, and is accommodating as to the time of flowering, either early or late.

For particular occasions, and in order to meet extra demands, we have kept plants, both stove and greenhouse, for days together in a Mushroom house. "Nothing to the advantage of the plants," the reader may retort, which we do not dispute, except to reply that "the end justifies the means." The indiscriminate adoption of such a principle would be generally condemned as extreme, except in the sense referred to.

There are many other plants of a commoner type that are indispensable for travelling purposes during the hotter months of the season. Amongst their number we would place pink and scarlet double Geraniums at the head of the list; their compeers, with more flimsy and delicate florets, have few qualities to recommend them to general notice for this particular purpose. Notwithstanding this, there are many families who would be unwilling to give up old favourites, such as *Crimson King*, *John Hoyle*, *Mary Hoyle*, and *Alba multiflora*, which can be had in flower early, and their ranks recruited with newer and better sorts, together with many of the Zonal section, which make admirable companions and give great variety in colour. Sharp forcing is never desirable with these flowers; but in case they are at all pressed, let them be shifted into a cool house in good time, and kept "right up to the glass," to give the flowers as much stiffness and substance as possible. They will be better of light, but no actual sunshine that is calculated to affect the flimsy framework of the opening trusses.

Advantage should be taken of dull cool weather, whenever the opportunity presents itself, to cut large quantities of these flowers. Previous to cutting, each flower should have a single drop of gum arabic, diluted to the consistency of water, dropped into the centre of each, which assists in keeping the petals together; and in packing let the flower trusses be strewn thinly over the surface of other flowers, so that they will regulate themselves into safe position on the first shake of the basket. Where there is an objection to carrying plants in flower into cool dark places, the flowers can be cut before they are fully open, and put in water in a Mushroom house or cellar, where they will keep quite fresh for two or three days.

Any flowers gathered from the open air had better be cut with a sharp knife before they are fully open in the cool of the morning, and treated in a similar way. As to packing, our own plan is simple: We have square baskets of different sizes, with tin trays 4 inches deep resting one above another inside,

the top one of each being a shallow one for Strawberries, divided into large and small compartments. There are, of course, duplicate keys here and in London. Shallow boxes from 3 to 4 inches deep are used for Camellias, which are tacked firmly to the bottom of the box; and a sprinkling of water completes the work. The tin trays are filled with the coarse flowers always in the bottom, and choice flowers are carelessly dropped in the vacancies between—we take care that each tray contains its full complement, so as to prevent violent vibration—and a layer of Maidenhair Fern covered with a sheet of silk paper concludes the packing, except a sort of rude baptism that is given as a reviver to keep the whole fresh on their nocturnal journey.—W. HINDS (in *The Gardener*).

MARGAM PARK.—No. 2.

THE SEAT OF C. R. M. TALBOT, ESQ., M.P.

HAVING on page 111 given a description of the general features of this fine place, we have now to add a few further details, treating more especially of its orangery, forcing house, and kitchen garden; and the first-named distinguishes it from all other places in Britain. It is not uncommon to see single Orange trees growing in conservatories, but at Margam we think the trees cannot number less than two hundred, which for size and variety are unequalled in any establishment in the kingdom. That the system on which the trees are grown is a sound one is evident by the success which has ensued. Many of them measure from 12 to 18 feet high, and from 12 to 16 feet in diameter; they are in perfect health, and carry heavy crops of fruit yearly. The treatment is different from that we are accustomed to see in the public gardens of France, where they are clipped in the close formal shape of a cone, and seldom, if ever, bear fruit. Here they are allowed to fully develop themselves, and the result of this and the general treatment is a profuse supply of fruit and flowers at all seasons.

The reason assigned for the existence of the orangery at Margam is this: The original trees of this collection, about a hundred in number, were sent from the King of Spain to Queen Elizabeth as a present, and the ship conveying them being stranded on Margam shores became with its contents the property of the lord of the manor. The original trees, still at Margam, are about three hundred years old, and have been in the family all that time, so it is no wonder that they take lively interest in them and their welfare. Many trees have been added to the collection since the first importation, and the original trees continue to flower and fruit as freely as those much younger. No doubt the climate and situation were favourable for their culture, but loving care must also have been bestowed on them to attain such good results. The trees were formerly sheltered during the winter months in a large old barn, which had been used by the monks of the abbey of Margam for keeping their grain, till the present Mr. Talbot's father erected the large Orange house shown in the engraving (fig. 19) accompanying this notice. It is a handsome building in the Doric style of architecture, extending to 355 feet in length by 30 feet in width, and 24 feet in height. On the broad terrace in front, where a great portion of the trees are placed in summer, there is a large and beautiful central fountain, with smaller fountains at either end.

Another and much larger portion of the Orange trees is arranged in a circle on a lawn adjoining, enclosed by thick arbours and stately trees of different kinds growing to a great height and affording fine shelter to them; while in the centre of the circle is a fountain with Water Lilies floating in its basin. Besides greatly adding to the beauty of the scene the fountains serve a useful purpose by keeping the air moist around them. The Orange trees are grown in square tubs about 4 feet wide and 3 feet deep, the compost being loam, leaf soil, decayed manure, and a little charcoal to keep it open. The tubs last from ten to twelve years. Once the tree is put in a tub it remains there as long as the tub lasts without receiving any fresh soil beyond that of top-dressing when it is required. The trees are well watered at all times and are never allowed to become dry at the root. They are watered two or three times a week with liquid manure from the pigstye during the growing season, which adds greatly to their vigour, freshness of foliage, and general productiveness. The singular sight is presented of seeing all stages of development of the fruit on the plant at the same time—ripening fruit, fruit just setting, and Orange blossom diffusing a pleasant aroma around. The fruit is preserved and used in different ways, as well as for

dessert. In a lean-to house close by of considerable length a number of Orange and Lemon trees have been trained up the walls and are bearing beautiful fruit. Planted in front of these are large Camellias, Fuchsias, Roses, and different kinds of greenhouse plants growing in great luxuriance, forming a kind of conservatory or winter garden for promenading during dull weather. About the middle of October the Orange trees are taken inside the orangery by means of a carriage specially designed to lift and carry them. The house is not artificially heated, the plants being hardy enough not to need this kind of protection, and they are placed outside again about the middle of May. Mr. Muir informed us that the plants were never subject to insect pests of any kind when treated in the way described above. The water for the fountains is obtained from an ornamental pond, which occupies a considerable area a short distance from the mansion and on a lower level to its right. It is usually well supplied with water from the drainage

of the adjoining wooded hills, and contains a good stock of trout. A visit to the orangery of Margam cannot fail to have much interest for all lovers of horticulture.

The kitchen garden immediately adjoins the gardener's house (which, by the way, is scarcely in keeping with the other fine features of the place) and is some five acres in extent; it lies to the north of the pleasure grounds, and is screened from them by large shrubberies and the back wall of the winter garden, which forms part of the north wall. Against this are sheds for different purposes, such as fruit room, store room, Mushroom house, &c. The south, east, and west sides are enclosed by high walls. It lies open to the south, and is sheltered from the north by the Oak-clad eminence already mentioned, and on all sides by plantations a short distance off. Though the garden is old the soil in many places is of a stiff clayey nature, and difficult to work in all kinds of weather. Notwithstanding this we found it in excellent order, and in a

Fig. 19.—THE ORANGERY AT MARGAM.

high state of cultivation. Mr. Muir devotes great attention to this department. As soon as one crop is cleared off another is put in its place at once. The eye is soon attracted to a large quarter devoted to thirty sorts of Peas grown for trial, which include many of the old leading sorts. They were bearing heavy crops, and looked all that could be desired in that respect. Of the newer sorts Culverwell's Telegraph is the best, possessing as it does every good quality desirable in a Pea. It is a tall-growing variety with large, well-filled pods of the very best quality. Next to this is Carter's Challenger, a dwarfier grower, but a prolific bearer of great merit, and which should be included in all collections. Veitch's Criterion comes next, not so prolific but fills well. Large breadths are planted with Broccoli, Brussels Sprouts, Savoys, and other winter crops, all in an advanced state of growth and looking well. We do not pretend to give the reader a description of the different crops grown here; suffice it to say that they all looked well, and it would be difficult to find a piece of empty ground or a better cultivated garden.

Many of the fruit trees on the walls are old, but the most of them were bearing tolerable crops, considering that this has not been a good fruit season generally. Standard Apple and Pear trees in the open quarters were very good, but not so heavily laden as is usual in good seasons. Gooseberries, Rasp-

berries, Strawberries, Red, White and Black Currants were abundant. The Raspberries are planted in rows 6 feet apart and trained vertically on strong wire trelliswork, and the ground is never dug between the rows. That the soil and this treatment suit them is evident from the heavy crops they carry yearly. We do not remember ever seeing better crops of Raspberries than those anywhere.

The forcing houses and Melon ground occupy a portion of the south side of the garden. The front range, or lean-to structure, consists of two vineries, a fruiting Pine stove, and a Peach house, each being divided into sections of 40 feet. The houses are old and in good repair, but not so easily worked for ventilation as modern structures. The first we enter is the early vinery, which is planted with Black Hamburgs and Foster's Seedling. The Vines looked old, and had a somewhat stunted appearance, but they were carrying a good crop of medium-sized Grapes which were nearly ripe.

Next to this is the fruiting Pine stove. It is filled with strong plants of Smooth-leaved Cayennes and Queens, all showing handsome fruits, some of which were half swelled, others nearly ripe, and all of them in robust health. The Smooth Cayennes would weigh from 5 to 6 lbs., and but for the want of a proper command of bottom heat they would have been much heavier. Tomatoes growing in pots and trained on

a trellis on the back wall were covered with large fruit nearly ripe. The next division is planted with young Vines, which are in a vigorous state (the old Vines being still retained till the young ones fill the house). They embrace all the leading sorts in cultivation. The end division is a Peach house and late vinery combined. Both the Peach trees and the Vines were carrying good crops, considering that this arrangement seldom if ever answers well. Behind this range are potting and other sheds. Succession Pine pits, Cucumber and Melon pits and frames, occupy the Melon ground.

In closing, we cannot but congratulate Mr. Talbot, the respected proprietor of Margam, in possessing such an interesting place. He has always been a liberal promoter of horticultural improvement, and it is gratifying to know that he has around him in such rich measure and in such a peculiar form the means of ministering to his cultivated taste. We would also compliment the head gardener, Mr. Muir, on the manner in which the place is kept, and on the successful way in which he manages a department of horticultural work so much out of the range of the experience of gardeners in general.—A. PETTIGREW, *Castle Gardens, Cardiff.*

LAYERING.

THE system of propagation by layers commends itself to the owners of woodlands as being at once a cheap, sure, and expeditious method of filling up blank spaces throughout their hardwood plantations. At a comparatively trifling cost, and in an incredibly short time, a straggling coppice may by this method be completely filled up without any outlay except for labour; and the growth of such layering will far surpass that from ordinary planting, inasmuch as the vigour of the well-established stool is at once imparted to the new shoots, which receive immediate benefit from the abundant root-growth of the parent.

It is not intended in the present paper to enter fully into the principles of layering, which would necessitate an explanation of facts belonging to the science of vegetable physiology, but to dwell more particularly upon the practice.

The method of arresting the sap in its descent by layering the gardener avails himself of in numberless instances. He propagates his Carnations, Pinks, Roses, and a number of other plants by making an upward cut about half the depth of the joint or node, and fixing the cut part by pegging or otherwise in soil favourable to its striking, by which means the latent fibre develops its roots. As the juices of the plant exude at the point of partial severance they form a spongy mass of cellular matter, which is technically termed *callus*, and from which the roots proceed.

But though this practice has long been a common one with gardeners and nurserymen, its adoption to any great extent by the forester is still an event of rare occurrence. Yet the possibility of its being successfully and almost universally applied to hardwoods upon most soils renders it deserving of careful consideration.

As a consequence of its continued connection with the parent stool the layer is not so entirely dependant upon the season as is a transplant; and on account of its rapidity of growth it is much sooner out of the reach of ground game, and beyond the destructive powers of Briars and fast-growing weeds of various kinds. And as the peg and covering of soil fix the layer firmly in the ground, thus preventing all the evils of rocking by wind which so often proves fatal to young trees, the system is admirably adapted to the seaside and to other situations of exposure. Moreover it is applicable to almost every kind of hardwood, including the Oak, Ash, Sweet Chestnut, Elm, Alder, Birch, Lime, Plane, Poplar, Hazel, Mountain Ash, and Willow.

The methods of layering vary according as they are applied to nursery stock or carried out in the woods themselves. In the nursery, where good soil and careful cultivation afford facilities for the production of an abundance of small shoots which may be layered for future transplants, it is customary to select those of one year's growth, and to layer as many of these as possible around the stool.

One mode in use among nurserymen differs slightly from that adapted to the majority of hardwood plants. This is termed *hillock layering*, and is often applied to the Apple, Plum, Quince, Hazel, Magnolia, and Fig. By being cut low during the previous winter the latent buds near the surface develop into shoots, at the base of each of which it is customary to raise a hillock of soil. By pinching off the tops of

the shoots they are induced to throw out numerous rootlets during the following summer.

Multiple layering may be resorted to with the Vine, Fig, Lapageria, &c., by laying one of the last year's shoots in a trench and covering its whole length to near the extremity with fine soil. Every joint or node may thus by careful treatment be made to produce a separate plant.

As instances of the nursery practice of layering for future transplants we may select the Elm and the Lime. In the case of the Elm plants are first set out in beds at from 5 to 6 feet apart; at the end of the third or fourth year these are cut over like osiers to within three or four eyes, and then layered immediately the shoots ripen in the following autumn. The land being thoroughly cleaned and well pulverised the shoots are bent down and covered with 3 or 4 inches of fine soil, and also pegged when necessary. They may be detached the following autumn by being cut away with a very sharp knife and then planted out in the nursery, great care being taken not to injure the roots during removal. The stool should afterwards be carefully and evenly dressed back. In this way each summer's shoots may be layered at the end of the autumn. In dry weather the transplants should receive liberal waterings.

To prepare lines for layering in the nursery they should be cut over very near the surface of the ground. At the end of the first year bend down and fix the shoots as in the case of the Elm, by which means they will be ready for removal by November. As soon as the one crop is cut away the next may be layered to replace them. To secure a liberal crop of shoots for layering the stools should be kept clean, and occasionally well dressed with a liberal supply of good compost or vegetable mould, adding some sharp sand in cases where the soil is deficient in silex. By this treatment after the end of the third year from sixty to seventy plants may be produced from a healthy and vigorous stool, and these will generally attain a height of 2 feet by the time they are removed. If planted out in good nursery soil at distances of 2 feet by about 20 inches they will in two years be nearly 6 feet high. By transplanting them in the nursery every second year, and giving them additional space at each removal, lines may be grown to a great size, and afterwards be planted out with perfect safety.

For plantation layering the shoots should be allowed to complete their second year's growth, when the soil around the stool should receive a good forking or loosening. For every shoot to be layered a small trench should next be opened in the direction of its length, and to a depth of from 4 to 6 inches. If the branch will bend easily into its new position without cutting this may be done, but if not give it a slash with the knife upon its under side, taking care to keep the bark whole upon its upper surface; a hooked peg from 6 to 8 inches long may next be driven into the ground to secure the layer, and some good soil trodden down upon it insures an erect position for the head of the layer, and cut off the top above the first bud. Such layers will sometimes make a growth of 4 feet the first season.

The time for severing the layer from its parent stool must depend very much upon the quality of the soil, upon the season, and upon the size of the layer itself; as the poorer the soil and the larger the layer, the longer the time required to insure its complete establishment, and *vice versa*. But in ordinary cases it may be cut away at the end of the second year, when only one round of layering is required. If necessary, the same shoot may be again layered at the end of two years, and so on in succession until the whole vacant place is covered, the final cutting away of the first shoot being delayed until the last layer has become well established.

Where the original stool is fixed in tolerably good soil the layering from it may be extended over rocky surfaces, especially with the Oak, where there is very little soil, by loosening the face of the rock and insuring for the layer a sufficient covering of earth.

Remunerative coppice may be reared upon this system of planting or filling up much more cheaply and expeditiously than by any other method. As an illustration, we will suppose a piece of land to be planted with hardwoods, triangularly placed at distances of 20 feet, and the intermediate spaces filled up with Larch or other nurses. At the end of the second year cut back all the hardwoods. Two years after this it would be possible to layer many of the new shoots to advantage, and this may be done at once wherever there are blank spaces. But, as a rule, it will be better to allow these to grow on for another seven or eight years, and then again cut back the whole, removing at the same time such of the nurses as

may be found necessary. If the shoots from the stools have been thinned out at the first cutting, both the remaining poles and also the nurses now cut away will, especially in Hop districts, now be worth a considerable sum. Two years after the second cutting of the hardwoods remove most of the remaining Larch, and layer in all directions. Continue such layering every two years, until the whole space is well filled up.

The writer is aware that in many quarters there exists a considerable amount of prejudice against the system of layering in plantations; but at the same time he is thoroughly convinced that a fair trial under favourable circumstances of soil and situation will convince the most sceptical of its advantages. From the middle to the end of August is probably the best time for performing the operation upon strong coppice shoots.—ALFRED J. BURROWS, *Pluckley, Kent* (in *Journal of Forestry*).

NOTES AND GLEANINGS.

THE nursery of Messrs. Veitch & Sons at Chelsea has a rich addition made to its already rich store of Orchids, and Mr. Dominy, the firm's famous hybridist, has achieved another triumph. The latest addition and striking acquisition is a NEW *CATTLEYA* raised by Mr. Dominy, and now flowering for the first time. It is the result of a cross between *C. Dowiana* and *C. exoniensis*—parentage which might have been expected to produce something fine, but such a remarkable flower as the one just expanded could scarcely have been anticipated. The most striking feature of the flower is its grand lip, grand alike in size and colour. The form of the lip is evidently taken from *C. Dowiana*, but where the colour has come from is one of those mysteries of Nature that occasionally evoke both our wonder and admiration. The lip of the new variety is 2½ inches broad and 3 deep, and the margin is undulated. The colour is not easy to describe, indeed it was possibly not quite fixed when we saw the flower immediately after its expansion. The prevailing colour, however, appears to be velvety maroon, very deep in the centre and shading to purplish violet, the undulated edge having a narrow wire of pale violet, and the throat is slightly veined with buff. The sepals and petals, which are 3 inches long, are a purplish magenta, the former being about half an inch broad. The whole flower is massive, and is suffused with a satiny gloss that renders it additionally attractive. It is unlike any other *Cattleya*, and is unquestionably a rich addition to a rich genus of plants. Three flowers are produced on one stem, and they well compensate for the ten years of waiting and cultivation which have been necessary to bring the plant to its flowering state.

— ONE of the finest and most extensive displays of BALSAMS that we have seen was in MESSRS. CARTER & CO.'S NURSERIES at Perry Hill, where special attention has been devoted to this popular flower during the present season. The plants are of course grown for producing seed. There are five thousand of them. They are grown in low span-roofed frames that the firm had made for growing annuals in pots early in the season. The flowers are now fading and seed pods are forming, but not in great profusion, for the simple reason that flowers so double as these are do not seed nearly so freely as semi-double flowers. Two distinct types of Balsams are represented—one a strong robust-growing sort with correspondingly large flowers, designated The Challenger; and the other dwarf, sturdy, and floriferous, with smaller but equally double flowers. The plants are arranged in groups of distinct colours—of white, cream, flesh, salmon, pale rose, violet, purple, plum, and crimson as selfs; other groups contain striped and marbled flowers, and then there are large groups in which all the colours are mixed. In order that the plants have good attention both as regards selection and culture they are placed in charge of a man who devotes his whole time to them, and who further acts under the immediate supervision of the firm's critical and energetic manager Mr. Sharman.

— AT the monthly meeting of the SCOTTISH HORTICULTURAL ASSOCIATION on Tuesday night, the 6th inst., the President in the chair, Mr. Alexander Honeyman read an instructive paper on the "Nutrition of Plants," dividing his subject into four heads—viz., How Plants Grow; On What Plants Grow; the Application of their Food; and the Influence of Light and Temperature. The essayist dwelt at considerable length on the different heads of his paper, and succeeded in putting before the meeting some of the principal facts that every gardener should make it his study to know. He con-

cluded by strongly enforcing the necessity of gardeners making themselves acquainted with the rudiments of chemistry, and expressed the hope that the time was not far distant when chemistry would be as widely known among horticulturists as it now is among agriculturists. Mr. Wm. Black next read a paper on the "Cultivation of the East Lothian, Warriston, and Ten-week Stocks." He described the modes of cultivation followed in the Dean Cemetery, where these Stocks grew so luxuriantly. Messrs. Dickson & Co. received a certificate for new Phlox Surprise, and Mr. R. Robertson received certificates for new Carnations Rosy Queen and Mrs. Robertson.

— WE last week referred to some attractive flower beds in Mr. Baring's garden at Coombe Cottage. Equally worthy of notice are other departments under Mr. Baker's care. VINES IN POTS for starting in October for producing ripe fruit in March are splendid. They are cut-backs, the canes being 15 feet long, strong, and studded with bold eyes. Young Vines planted out are also in a most promising state. Peaches under glass have just ripened a fine crop and are now ripening their wood. The lights are removed on account of alterations being made, otherwise they would have remained on the principle that it is heat, not cold, that ripens wood. A fine pit of the Criterion Tomato, which Mr. Baker considers the best variety in cultivation, is affording fruit in abundance. Plants throughout the houses are in excellent condition. Orchids are numerous, healthy, and clean; several plants imported this spring appear quite established and are making remarkable growths. Gardenias grown in large pots and plunged nearly over the rims are most luxuriant and produce blooms continually, and Stephanotis overhead is producing wreaths of wax-like flowers. To brisk heat and abundant supplies of water the satisfactory condition of these and other tropical plants is attributed.

— FEW men work harder than those employed in nurseries, and a day's recreation now and then is well merited by such men. We observe by a local paper that the *employés* of Messrs. Carter & Co. of Perry Hill and those of Messrs. J. Laing & Co. of Forest Hill have had a change of occupation—namely, a day in the cricket field. The representatives of the Perry Hill Nursery were the victors.

— IN visiting gardens in different districts we occasionally come across the DUKE OF BUCKLEUCH GRAPE thriving satisfactorily. At East-Cliffe House, Lincoln, a Vine in a mixed house has this year produced seven good bunches, and the berries are not only admired for their splendid appearance, but are highly esteemed for their superior quality. The owner of the garden referred to, Mr. N. Clayton, has all the best varieties of Grapes, but none is so much enjoyed as "the Duke." A few of the berries are slightly spotted, but others are perfectly clear, and measure 4½ inches in circumference. The Vine is on its own roots and has grown as freely as any of the other Vines in the house. Mr. Wipf, the gardener, states that it bears freely enough when not too closely pruned, but if the laterals are cut off close to the old rod it is not certain to produce bunches. When well grown this is certainly a noble Grape of splendid quality.

— WE have received from Mr. H. Cannell, the Nurseries, Swanley, some flowers of BALSAMS of remarkable quality. None of the blooms are less than 2½ inches in diameter, and they are perfectly double and imbricated. The colours are white, flesh, scarlet, violet, and crimson, many of the darker flowers being further marbled with white. The flowers sent to us represent an excellent strain.

— MR. GODWARD, The Royal Nurseries, Southend-on-Sea, writes:—"I have the *EUCALYPTUS GLOBULUS* growing in my nursery which is now showing bloom buds. Can any of those who read your Journal inform me if this tree usually blooms in this country? The seed was sown in March, 1876, and the seedlings were planted out in June the same year. It is growing rapidly, and has attained the height of about 20 feet. If the *Eucalyptus* grows in other parts of England as it does here it must become a valuable tree."

— THE *Irish Farmers' Gazette*, after referring to the excellence of the plants and cut flowers exhibited at the Royal Horticultural Society of Ireland's Show, states that the SHOW OF FRUIT was magnificent, the display of Grapes being one of the best ever seen at the Society's Exhibition. The Veitch Memorial medal for the best three bunches of Muscat of Alexandria was deservedly won by Mr. Roberts, gardener to the Countess of Charleville, with a stand

which well supported his reputation as one of our foremost Grape-growers, the bunches being splendidly finished and in every way models of cultural skill and care. The bunches exhibited by Mr. Hawkins, Belfast, were next in merit, and reflected credit on the skill of his gardener, Mr. Magee. The Hamilton fruit prize for the tray of six bunches of Grapes was also won by Mr. Roberts with grand bunches of Black Hamburgh and Muscat of Alexandria; the second prize was awarded to Mr. Hawkins, and the third to Mrs. Daly, the stands exhibited by each being of high merit. Nectarines were first-class, notably those from Emo Bark, the best variety being Victoria. For Peaches Mr. Kirby, Killester Garden, was first with a dish of marvellously sized fruits of Walburton Admirable; the second place being awarded to Mr. Wilson for Noblesse. Figs were good. Of Pears, Plums, and Apples there was only a small display, but Gooseberries and Currants were largely shown. The show of vegetables was first-class, all the collections, some fourteen in number, being good; the best were, however, those exhibited by Mr. Corballis and Col. Nugent.

— It is a little surprising that the distinct and brilliant *BEGONIA FROBELLII* is not more extensively grown for autumn decoration. Usually we find plants more or less drawn and attenuated by having been grown in too much heat, and in that state they are not attractive. We have recently seen plants raised from seed sown during the spring of the present year that are dwarf, healthy, and vigorous, and just showing a profusion of flowers. The plants have received much the same treatment as Primulas, and are now growing in cool frames.

— **PRESERVING PEAS GREEN.**—The following is extracted from the "Rural New Yorker":—"Never attempt to can peas in glass or earthenware, as all efforts to do so have proved unsuccessful. Provide strong, new tin cans, and the necessary conveniences for soldering. The peas should be fresh from the vines, and cooked as soon as shelled. Boil the peas in water sufficient to cover for ten or twelve minutes, seasoning with a little salt; then fill the cans two-thirds full of peas, adding enough of the liquor in which they were boiled to fill to the brim. Wipe the groove dry, put on the cap, and solder airtight at once. Make a small puncture in the centre of the top, and place the cans in a boiler of hot water, to boil for an hour and a half. Have something at the bottom of the boiler, as broken crockery, to keep the cans off from the bottom. Take the cans out from the boiling water, one at a time, and open the puncture with a needle, to allow of the escape of gas and steam. Then solder it tightly, and return to the boiler to boil two hours longer—even three will do no harm. If the cans are still airtight one need have little fear of fermentation of their contents."

— **THE EMPLOYÉS** of Messrs. Sutton & Sons, the Queen's seedsmen of Reading, with their wives and friends, and accompanied by the members of the firm and their families, numbering in all between three and four hundred, had their annual excursion on the 2nd inst. Brighton was the place chosen, and at 7.10 A.M. a special train left Reading, reaching Brighton at ten o'clock. On arrival lunch was partaken of, and the party afterwards availed themselves of the numerous attractions of this favourite watering place; some visited the Aquarium, while others tempted by the calm sea went sailing in three yachts. At 1.30 the whole party assembled for dinner, at the conclusion of which Mr. M. H. Sutton, Mr. A. Sutton, Mr. M. J. Sutton, Mr. H. Sutton, and Mr. Arthur J. Sutton severally addressed those present. Again separating the beautiful neighbourhood of Brighton, the pier, &c., were visited by the excursionists, and at 6.30 the whole party were entertained at tea by the firm. At 8.10 in the evening the train left Brighton, and after a very rapid run reached Reading at 10.30. No accident happened to mar the pleasure of a most enjoyable seaside trip provided by the liberality of the heads of the establishment.

— We regret to have to announce the **DEATH OF MR. ROBERT SIM**, of Foot's Cray in Kent, at the ripe old age of eighty-seven. The sad event happened on the 3rd inst. Mr. Sim was very well known as an ardent cultivator of Ferns, and there was perhaps no better British pteridologist living than he was. He has died as full of honour as of years.

— "NATURE" says, "We have received from Messrs. Eberstein of Dresden a specimen of an interesting 'WALKING-STICK' for naturalists or tourists. The stick is a perfect *multum in parvo*, and contains quite a museum of scientific instruments.

The handle alone contains a compass, a double magnifying glass or pocket microscope, and a whistle. Below it there is a thermometer on one side of the stick and a sand-glass on the other. The body of the stick is partly hollow, and in its interior holds a small bottle, which is intended to contain chloroform or ether for killing insects. Along the outside of the body there is a half-metre measure, showing decimetres and centimetres. Near the end of the stick a knife-blade may be opened, which serves for cutting off objects which cannot be reached by hand, such as aquatic plants, &c. At the extreme end a screw may hold in turn a spade for botanists, a hammer for geologists or mineralogists, a hatchet, or a strong spike, which would be of great use on glaciers. The whole is neatly finished in black polished wood."

— **THE American "Gardener's Monthly"** refers as follows to the **DEATH OF MR. JAMES FLEMING**:—"This well-known seedsman of New York died at New Canaan, Conn., on July 10th. Mr. Fleming was born in Ayrshire, Scotland, in 1833, and was consequently forty-five years of age. He was an excellent type of the best class of Scotch gardeners, an educated intelligent man, thoroughly versed, not only in the varied details of all the branches of horticulture, but was besides an excellent botanist; but his character was so innately modest, unassuming, and unpretentious that only his most intimate friends were aware of his varied acquirements."

FERNS IN NEW ZEALAND.

NUMBERS of Tree Ferns are sent away to Europe to delight the eyes of Fern lovers with their beauty. Sometimes when passing through bush clearings, amidst the blackened remains of thousands of Fern stems, one is almost tempted to regret that there should be a limitation to the carrying capacity of ships, so that more of our forest beauties might be preserved. Let us devote a few lines to the service of owners of bush land, an appeal to their cupidity—we mean conservatism, which we gather from catalogues of Fern-growers of the first class in Europe. The common Silver Tree Fern, with stems of 6 to 8 feet, appears to be retailed at prices varying from £25 to £42 each, specimens of *Dicksonia squarrosa* at £21 each, *D. antarctica* at prices that range up to £5 5s., whilst our *Hemitelia* appears to be unknown, at least to the trade of Fern dealers. After this statement of the value of Ferns among an appreciative people, may we not hope to have the ever-ready match sometimes withheld, and many a picturesque Ferny glen spared from the flames by the proud owner of so much forest wealth, only requiring transport to its distant market? Whether our hopes are well founded or not we cannot help mentioning a specimen Fern. Seen about three months ago it would have made any Fern cultivator eager for its possession. On the bank of a mountain creek, where lofty trees grew sparingly, stood a majestic specimen of the Silver Tree Fern, its noble head well decked with wide-spreading fronds, hugely expansive; the rough brown stem for some 20 feet laced over with the twining cords of the large-flowered *Clematis* (*C. indivisa*). Just below the towering crest of this grand Fern, amidst ample wreaths of dark shining foliage, glistened the pure white blossoms of the lovely creeper, glorious in their bountiful profusion; here and there some of the snowy garlands with clinging reach stretched over the green canopy of fronds, swinging in the soft breeze, with the wild coquetish grace of Nature. Poets have often sung of the Ivy or Vine clinging to the sturdy Oak—

"The female Ivy so enrings the bark of the Elm."

Could any of these sylvan marriages surpass in picturesque beauty the union we have just attempted to describe, where the stately Fern upheld the trembling *Clematis*, arrayed in all her charms of bridal purity?

We have been looking upwards so long at tall Tree Ferns that it is time to lower our gaze and begin to make acquaintance with the *Hymenophyllæ* or Filmy Ferns. We shall now, therefore, have to peer into shady ravines and gullies, search amongst rocks, tree stems, and mosses, in order to find these fragile members of the Ferny tribe. In writing of the *Cyatheæ* we have had constantly to speak of measurements of many feet, now we shall have to deal with many of the minute forms which give such variety to the collections of the Fern-grower. Our country is very rich in the number of species of *Hymenophyllæ*. This extensive group is divided into three genera—viz., *Hymenophyllum*, *Trichomanes*, and *Loxoma*; of these the two first are generally distributed, whilst the last-

named is restricted to a few localities in the North Island. The delicate members of this extensive division are greatly prized by cultivators in the old country; they make pets of them, they take an infinity of trouble to ensure their successful growth. To show this fully let us jot down a few instances from well-known writers concerning but one species, and that perhaps one that we should consider one of the least interesting. Concerning the almost cosmopolitan Tunbridge Fern, far more common here than in England, Shirley Hibberd writes thus:—"A cynosure, a paragon, a paradox." We wish this enthusiastic Fern-grower could see our *H. scabrum*, *dilatatum*, *polyanthos*, or *demissum*, some of them in broad spreading masses covering perches of ground, and forming colonies by ascending and annexing neighbouring tree stems. The author of "Select Ferns and Lycopods" incidentally proves how much the Filmy tribe is appreciated. Writing of the same species that called forth praises from Shirley Hibberd he states as follows:—"We have had *Hymenophyllum tunbridgense* growing in a very small glass case—in fact, in a bottle, for the last two years, in a little silver sand at the bottom, and the bottle corked up tightly so that no air can get at it, except when the cork is removed to give it a little moisture." *H. tunbridgense* is found in many parts of Europe, Asia, Africa, South America, as well as Australasia. Here it may be collected from the coast to the backbone of the interior, covering rocks damp rather than wet, on the roots and stems of trees, amongst moss where any great amount of moisture is carried off by rapid drainage. We have seen it growing on the dry clay or cob in a *Fagus* forest, where it has drooped perpendicularly. In the Alpine country it may be noticed nestling in sheltered nooks of gullies, where during winter months the cold is most intense, the locality often above 2000 feet over the sea level. Here it may be grown without much difficulty either indoors or out by the cultivator who will afford it abundance of shade and put his faith in sandstone. However, we must leave this elegant toothed species, and turn to others which have greater claims on us from their greater beauty. *H. bivalve*, another member of the group that have their margins toothed, is indeed a lovely species. It grows in the densest masses; fond of moisture, its beauty is displayed to the greatest advantage in spots where a mountain spring moistens well-shaded rocks. A few weeks since, in a bush that shuts in the head of one of the secluded bays of the Banks Peninsula we saw a grand mass of this delicate plant. On the slope of the hillside glistened a patch of the deepest verdure, measuring some 70 yards in length, with a width varying from 3 to 10 yards; this was one continuous mat of *H. bivalve*. In all probability this lovely example of this Fern has been since destroyed, as bush fires have been raging on the Peninsula, settlers taking advantage of the present extraordinarily dry season to effect wide clearances. *H. multifidum* does not require much remark after the preceding species, which it resembles pretty closely, but it has the margins more sharply toothed; like *H. bivalve* it has a wide distribution over both islands. The little pendulous *H. rarum* differs very much in habit according to the locality in which it is found. Near Christchurch some of the dwarfer forms may be observed near the top of the small patches of bush that dot the native reserve at Ruapaki; it enjoys plenty of light and air, yet requires shelter. It is found to grow very well in moss on sandstone. It is a beautiful object in the fernery, and well repays the toil of collecting and some expenditure of trouble in making it grow freely. From *H. rarum* we follow Dr. Hooker's arrangement and next take *H. pulcherrimum*, one of the most beautiful of the genus; in fact, the learned author of the "Handbook," in his description of this Fern, writes thus:—"Tall, stout, bright green, very handsome." It owes much of its loveliness to the glossy wings which are continued to the base of the stipe; pendulous from trees, it is indeed a gem amongst Ferns. In the depths of the West Coast bush it grows luxuriantly, reaching in length some 20 inches. Perhaps we have no nearer locality than the Otira to give as an habitat; amidst the wild picturesqueness of that far-famed gorge, in some favoured nooks may be collected the lovely *H. pulcherrimum*.

The broad Filmy Fern, *H. dilatatum*, occupies the first position as regards size, and in the opinion of some collectors its claim for beauty entitles it to the first rank amongst the group under consideration. Its large almost transparent fronds, often carried erect or only slightly decurved, differ greatly in form; some are ovate, broadly ovate, or oblong. In the great Westland bushes, or amongst the woods that fringe the deep fiords and inlets or sounds of the west coast of the Middle

Island, the area covered by some of these beautiful species (such as *H. dilatatum*, *demissum*, or *T. reniforme*), must be reckoned or guessed at possibly the square mile; yet who has ever felt sated with gazing on their verdant forms, so varied, yet all so lovely? Their rhizomes creep along the surface of the ground, their transparent foliage covering rocks and gnarled roots; wide-spreading, aspiring, they ascend the stems of lofty trees whose expansive branches are gaily and thickly festooned with elegant garlands of those delicate Ferns. What woodland beauty can surpass that of a gigantic Rimu (*Dacrydium*), the resort of numerous parasites? From every branch sway vines and cords of climbing shrubs, its own pendulous foliage in itself a very fountain of verdure, its drooping limbs arrayed with these graceful green trappings, the sunlight excluded, subdued, or dimmed with the dense masses of translucent fronds gently waving from aloft like tiny banner-rolls amidst the glow of crimson Rata and the scarlet trumpet bloom of *Loranthus*, the long leaves of *Freyinetia*, as it twists like a huge boa around some mighty stem with close embrace. Ah! think of a scene like this, and then in fancy turn to peer in on the poor Tunbridge Fern imprisoned in a close-stopped bottle! But in truth it must be said this incident of the little prisoner has often lent a keener relish to the enjoyment of some delicious bit of woodland scenery, and we have often wished it possible that this good enthusiastic Fern-grower could share the delight of rambling through some fair paradise of Ferns where the Filmy tribe luxuriated in all their lavish beauty. *H. crispatum* or *javanicum* is sometimes found with a very tufted habit. It is very hardy, as we have had it from the Havelock River over 2000 feet above the sea level; we have collected it nearer Christchurch in the Malvern Hills, growing sparingly in company with *Polypodium australe* and *P. graminifolium*. It is easy of cultivation, and grows fairly well on soft sandstone, good drainage indispensable. *H. polyanthos*, another hardy Filmy, which would probably grow well in the west of England or Ireland, enjoys a most extensive range both within the colony and also abroad. A large proportion of the Canterbury district is, either from its lack of forest land or from its dryness of climate, but an indifferent habitat for Cryptogams, still there are places where some thrive, and certainly amongst the prettiest of these must be included *H. polyanthos* or *H. sanguinolentum* (by-the-by the latter synonym is derived from the peculiar odour given out by the plant in a dried or half-dried state). To see this Fern at home let us cross the wide Canterbury plains, whence the wicked squatter has been driven, and where industry and energy has compelled the tussock-clad wilderness to yield its golden crops of grain; from the plains as we ascend the hills we ramble amongst creeks that sweep over the famous coal beds of the Malvern Hills. Now for our Ferns; we follow the devious course of a small but rapid river, whose shallow stream is specked with many a jutting rock, or here and there shelved by ever-shifting gravel spits, over the edges of which the swift stream rattles noisily. After a long tramp we enter the welcome shade of a *Fagus* bush lying somewhat high amongst the hills. On the outskirts everything looks dry and unpromising for Ferns; we pass battered *Ti Palms*, prickly-leaved *Cyathodeas* and brownish *Dracophyllums*. Soon we reach a different scene. Under the broad-foliaged *Panax*, *Griselinia*, and berry-bearing *Coprosma* which shade the water-worn banks, where broad-topped *Fagus* trees, black-stemmed and lichen-mottled, stand somewhat thinly scattered, on dryish clayey banks, over rocks and stones, more rarely on stumps and boles of trees, we may find the thickly matted masses of our Fern, fronds of medium size, let us say 6 to 8 inches in length, in patches of many yards extent; it forms a close-set velvet pile, mostly of darkest emerald hue, shining and bright. Under the hot breath of the desiccating nor-wester it becomes crisp, even brittle to the touch, its brightness has departed, the fronds curled up assume the appearance of dried seaweed—apparently it is destroyed; yet see it under the reviving influence of a soft shower or heavy mist, and own its beauty. Dew glides along the winged rachis, gathers into a lustrous drop with shifting lights and rays of colour like the sparkling fires of a fine opal, it weighs down the point of the glistening frond ere it falls dispersed on the translucent foliage of the matted Ferns below. *H. polyanthos* is an unfailing weather gauge, giving a faithful record of atmospheric changes which the observant may readily interpret; its vitality should make it valuable to the Fern-grower, as it will survive much ill treatment. From our own experience in the open air fernery its most persistent enemy is to be found in that Ishmael

amongst birds, the Weka. Beneath the imbricating fronds a goodly number of insects find refuge; this causes our friendly Weka to make use of his investigating bill as a convenient instrument for clearing the fernery from insect pests. His work in that direction is fairly entitled to the praise of being called thorough.—G. (in the *New Zealand Country Journal*).

(To be continued.)

NOTES ON VILLA AND SUBURBAN GARDENING.

KITCHEN GARDEN.—Attend to the directions given in previous calendars as far as regards hoeing and clearing the ground of weeds, in order that neatness and regularity may prevail in every part of the garden. Clear the ground of decaying Pea haulm, Potato haulm, or old Cabbage stumps, and fill the ground again at once with Coleworts, Winter Spinach, or a sowing of Turnips. Advantage should be taken of moist weather both for sowing and planting, and the seeds will germinate the sooner and the plants become more speedily established. To ensure a sufficient supply of Spinach throughout the autumn and winter months sow a breadth at once, and again towards the end of the month. The first sowing will in all probability furnish an abundant supply of large green leaves throughout the autumn, while the crop from the latter sowing will not be nearly so succulent, and consequently harder and the more likely to withstand the severity of the winter. The prickly-seeded or Flanders is the best for this sowing, and should be sown in drills from a foot to 15 inches apart, thinning the plants to a few inches apart between the plants.

The orthodox time for sowing Cauliflowers for a supply during May and June of the following year is about the 20th of the present month, but this may be varied a few days either way in accordance with the district. In the north and colder districts the 20th is quite late enough for sowing, but in the southern or warmer parts towards the end of the month will not be found too late. Experience teaches us that if the plants be sown too soon they are apt to button, and on the other hand if sown too late they will not be sufficiently strong to pass the winter. Sow Walcheren and Early London varieties on a border of light soil, and water the seed bed occasionally if dry weather ensue.

Cabbage seed may yet be sown if sufficient seed has not germinated from former sowings. None will be found better and sweeter when cooked than Wheeler's Imperial. We grow quantities of this variety planted only about 15 inches apart, which supplies us with small compact tender heads. If a larger variety is needed the Enfield Market and Battersea are well known standard sorts.

Carrots sown now on dry warm borders will be found most useful for drawing during winter and early spring, especially on those soils where there is a difficulty in obtaining a sufficient supply from the spring or main-crop sowings. Early Horn is a useful variety.

Sow both the Flat and Globe Tripoli Onions, to be transplanted in the spring for making large bulbs and for using in a young green state. Pull those bulbs of winter-sown Onions that are well matured, and bend the necks down of those that are yet green and upright, also lay the crop of spring-sown varieties; these will also soon be in a fit state for pulling and laying on their sides to ripen off previously to storing for the winter. Garlic and Shallots will be fit to take up, and may be treated in the same way as described for Onions.

Spring-sown Parsley has this year been a failure in many places, and later sowings have had to be resorted to. Make another sowing for winter and spring use, and transplant any of the previous crops in warm sheltered situations. In places where Parsley is growing strong and luxuriantly it is a very good plan to cut down close to the ground a portion of the crop. The young new growths made after this time withstand the winter much better than the summer-made growths, which in hard weather speedily turn brown.

Sow Endive at once. Fraser's Broad-leaf and the Batavian are hardy varieties, and when well bleached are useful for salads, or they are often used boiled as a vegetable as a substitute for Spinach; the Moss-curl is also one of the best for the earliest supply. Plant out those already strong enough to transplant. Sow the Black-seeded variety of Brown Cos Lettuce for withstanding the winter. Transplant others to have an abundance for the filling of cold frames and other appliances to carry on a full supply up to Christmas. Radishes, Mustard, Cress, and Chervil may also be sown as required. They will be found to keep longer fit for the table than those that have been sown during the previous month. Gather Mint, Thyme, Marjoram, and other herbs for drying, and when dry let them be put in paper bags for use during the winter months.

Lift Potatoes as they approach to maturity and before the disease attacks them. Early varieties on light soil are more or less diseased, but late varieties up to the present have escaped the murrain. Plant out more Celery, and water that already transplanted to enable it to make a rapid growth.

Strawberries.—The planting of new plantations must no longer be delayed if good fruit is expected from them next year. Runners that were recommended to be layered in pots will now be in fine order for planting out, and will make plump crowns and well-established plants by the end of the season; it is from these plants that very large fruit may be expected. The Strawberry delights in a deeply trenched and well manured soil. The runners of all sorts are now in good order to be taken off for propagating, and may be planted thickly in a nursery bed, from which they can be transplanted permanently at some future period. Remove all runners and superfluous growths from established plantations, but do not adopt the barbarous system of cutting all the leaves, and run the hoe lightly through the ground to make all neat.

Conservatories can be now kept gay with tuberous-flowering Begonias, Lilliums, Gladioluses, Balsams, Cockscombs, Fuchsias, and zonal Geraniums, relieved with Ferns, Caladiums, and other fine-foliage plants. As soon as Achimenes, Gloxinias, or other stove plants go out of flower or show signs of distress remove them at once to the stove before they receive injury by being kept too long in too low a temperature. Tuberous-flowering Begonias are now grown in great profusion, and from a single packet of seed a quantity of varieties may be raised. Messrs. Laing & Co. of Stanstead Park exhibited a large collection at the Royal Horticultural Society recently, which had, with a few exceptions, been all raised from seed sown in January of this year. Their easy culture, compact and floriferous habit, recommend them to all growers with limited means. With the help of a frame or ordinary greenhouse these Begonias may be well grown. The tubers if potted about April in a light, sandy, friable loam will soon make decorative plants, or they may be planted out in the open ground in May. Several varieties are planted out in Battersea Park, and they produce a brilliant yet elegant effect. As the plants in pots go out of flower water must be gradually withheld from them, and the soil should be kept moderately dry throughout the winter and safe from frost. Of the named varieties Vesuvius, Emperor, Sedeni, Feu de Joie, Moonlight, John Laing, Paul Masurel, Oriflamme, and Gloire de Nancy, are all good, and so are many others.

WORK FOR THE WEEK.

MUSHROOM HOUSE.

COLLECT from day to day the droppings of horses fed upon dry food, as those of animals fed upon green fodder are not suitable for the growth of this esteemed breakfast delicacy. They should be had with about a fourth part of short straw, and spread out thinly upon the floor and shelves or other places protected from the weather. In some instances the horses stand upon sawdust, hence the droppings cannot be collected without a portion of the sawdust. This kind of material forms good and durable beds; but we prefer to add a fourth of straw, though that is not essential to the production of Mushrooms, yet from its steady decomposition is alike favourable to the heat of the bed and the vigour of the mycelium. In other cases the procuring of droppings fresh from the stables is unattainable; if had at all they must be taken from the dung yard. In that case the droppings must be shaken out with a fork, rejecting the long litter; and being done well—i.e., as much straw removed as possible, a very good material is obtained, and one that may be employed at once without fear of overheating. In all the above instances the staple is horse droppings with a portion of straw. Some prefer an admixture of loam, but unless very fibrous we have not found any advantage from its employment other than for the surface of the beds. Other material than horse droppings grows excellent Mushrooms. The finest we have seen were produced by sheep droppings, hay, and Oak leaves, the *débris* of a sheep pen, the hay and leaves being about equal to the bulk of the droppings. Good Mushrooms are also had from Oak or Beech leaves mixed with an equal quantity of horse droppings, and from those and straw saturated with urine, &c., from stable and cow houses with an admixture of a fourth part turfy loam; but the principal agent in the production of Mushrooms being nitrogen those substances that afford it most abundantly are the most likely to afford the best results providing the material be not allowed to heat, as in that case a large proportion of the nitrogen would be given off in the form of ammonia; therefore in preference material that has not heated is to be chosen.

Whatever the material may be it must neither be very wet nor thoroughly dry, but just sufficiently moist to form when beaten a firm close mass. When a sufficient quantity of the material is collected for the formation of a bed, which may be of any size according to the means and requirements, throw it into a heap with a base of about 4 to 5 feet, and a yard in height in the centre. In three or four days a gentle heat will be generated, when the material may be formed into a bed by placing a layer of 2 to 3 inches thickness, beating firmly with wooden mallets, then another, and so on until a depth of 12 to 14 inches is secured of thoroughly solidified compost. Some employ water, but unless the material be too dry it is better omitted, and in case of its necessity employ no more than to make the manure compress. In the case of the

manure being too wet it must be laid thinly on a floor in a dry shed and be turned over frequently, or a portion of dry short straw may be mixed with it; yet droppings saturated by rains are of very little value for the formation of Mushroom beds, for the spread of the spawn and the development of the Mushroom from the mycelium depends upon the steady decomposition of the material, old spent droppings being practically useless. In four days, or from that to a week, the heat will be (as it is termed) up, it may be to 90°, 100°, or more. When it is above 90° make holes about 4 inches deep and 9 inches apart, which will let off any rankness and to some extent lessen the heat. Insert the bulb of a thermometer 4 inches deep into the bed, and when the temperature declines to 80°, and not less than 75°, place in every hole a piece of brick (spawn) 1½ to 2 inches square, making sure that it is thoroughly permeated with the mycelium of the Mushroom, and fill the holes with the material of the bed firmly, the pieces being about 2 inches beneath the surface. In a week remove a piece of the brick, and if the material of the bed in contact with it has been infested with the same white small threads that the brick exhibited when inserted return the piece to its place and cover up, and at once proceed to earth the bed. Turfy loam neither heavy nor light is best, that taken off a pasture with its turf about 3 inches thick and stacked up for six months. This, chopped up fine, and in a medium state as to moisture, being neither wet nor dry, yet sufficiently moist to heat into a firm mass, put evenly over the bed 2 inches thick, either treading or beating with mallets firmly, and finishing off by beating with the back of a spade and smoothing the surface with the same. If it cannot be smoothed the surface must be watered, afterwards smoothing with the spade. In about six weeks the Mushrooms will begin showing; the bed should then be watered gently, or damped by the syringe every day until the surface is brought into a moist condition, but avoid anything like soddenness. Except in the case of beds in draughty sheds we never use hay, but in dry draughty places a covering of soft hay about 2 inches thick is desirable to secure to the beds an uniformity of heat and moisture. In the Mushroom house proper hay is not necessary. In watering care must be had not to water over the Mushrooms indiscriminately, but avoid them by damping between or pouring the water just a little from the spout. The floor and other available surfaces must be kept damp. No fire heat is needed, only to maintain a temperature of 55°. If the house be infested with woodlice it is well to place some boiled potatoes at the angles formed by the wall and floor or shelves, covering with a little hay, and in the morning pour boiling water over the hay. Prevention is better than cure, it being desirable to start with a thoroughly clean house, as if only a few of the pests are present they will increase rapidly and be sufficiently troublesome before the forced Mushroom season is over.

FRUIT HOUSES.

Figs.—The second crop of Figs on the earliest forced trees will now be ripening or ripe, and should not receive more water at the roots than to maintain the foliage fresh, and syringing must be discontinued or the fruit will crack, besides being deteriorated in flavour. A free circulation of dry warm air is essential to the ripening of the fruit and wood. When the fruit is all gathered the main point is to secure the proper maturity of the growths, which if due attention has been given to stopping and thinning the shoots little will now be required except attention to ventilation and watering, which last should only be given to prevent the soil becoming too dry, and of the former they can hardly have too much, provided the air be warm. The syringe should be laid aside, only calling it into requisition as a means of subduing insects. Upon the ripening of the wood depend future crops, therefore the circulation of warm air must be maintained until the leaves die off naturally. Any trees crowded with foliage should have the shoots thinned, so as to admit light and air to those retained to insure their thorough ripening. Trees that ripened a first crop in June will soon be ripening the second crop, and should be liberally supplied with manure water if the crop be heavy and the trees at all weakly; but if vigorous and the crop not heavy clear water will be all that is wanted, with syringing overhead twice a day, proceeding as before advised when the fruit commences to ripen. Excepting trees in pots Fig trees should not at any season be exposed to the weather by removing the lights, but should have abundant ventilation; but those in pots, from growing less vigorously than trees planted out, are the better if exposed to open-air influences after the crop of fruit is gathered, selecting a sheltered sunny situation, which will do much to invigorate them and harden the wood.

ORCHARD HOUSE.

Apricot trees that have ripened the crops of fruit should be well syringed for some time to thoroughly clean the foliage. Those in pots when the fruit is gathered may with advantage be placed in a warm situation outdoors, the pots being plunged in ashes and placed upon the same to prevent the ingress of worms. They must be thoroughly syringed every evening. It is wonderful what influence the sun has upon the young wood and spurs in plumping the buds and ripening the wood. The roots must not be neglected for water. In cold localities the placing of these and Peach and

Nectarine trees in pots outdoors after the fruit is gathered is not advisable until the leaves begin to die off naturally, therefore our northern friends will act accordingly.

Peaches and Nectarines ripening their fruit will not require so much water at the roots as when the fruit is swelling; but though a lessened supply is desirable it must not be withheld so as to cause the soil to become dry, or the foliage will suffer and future prospects be jeopardised. The trees should be gone over daily for the removal of ripe fruit, the hand being by far the best agent in gathering the fruit. Even a net is not advisable, as the fruit in that case is deteriorated from over-ripeness, and if the fruit have to remain in the fruit room after gathering for a few days it is superior to that falling from the trees. The trees after the fruit is gathered may be placed outside as advised for Apricots, they being thoroughly syringed to free them of red spider, &c. Trees planted out ought, as soon as the fruit is gathered from them, to be syringed every evening, and water afforded the roots to maintain the foliage in a healthy condition.

Plum trees swelling off the fruit must be well supplied with water at the roots, and liquid manure up to indications of ripening, when a somewhat lessened supply is desirable, syringing at that time ceasing, or the fruit will crack and be poor in flavour as compared with those that are ripened under drier or more favourable circumstances; but late kinds of Plums, as also Peaches and Nectarines, to be well supplied with water and syringed every evening. Plum trees, when the fruit is all gathered, should be placed outside in a sunny situation, cleansing the foliage with water from the garden engine.

Pear trees in pots when in duplicates may, as regards a portion of the trees, be placed outside, indeed there are very few Pears that are not improved in flavour by placing them in the open air to ripen; and with a view to prolong the season of some early kinds, that at most keep but a few days after being ripe, a portion of the trees may be placed behind a north wall, thereby retarding the ripening of particular varieties.

Grapes growing over the pathway or orchard houses will now be ripening. The syringing in their case must cease, the laterals being kept well stopped, they should also have a good watering at the roots; but other descriptions of fruit trees should be kept somewhat dry at the roots as the fruit approaches maturity without withholding water so excessively as to cause premature falling-off of the foliage or retarding the ripening of the crop. Not much stopping will now be necessary, but it must still be practised upon irregular and gross growths, and superfluous shoots should be removed altogether. Admit air abundantly day and night, except when the latter is cold, or during the prevalence of high winds. Wasps and birds are both numerous and voracious; they are best excluded by hexagon netting over the ventilators, the wasps being tempted to drown themselves by hanging soda water bottles outside the house half filled with sweetened beer.

PLANT HOUSES.

Stove.—It is fully time to give more than ordinary attention to flowering and other stove plants in conservatories, as the nights at this season, though the days may be bright and hot, are frequently low in temperature, in which case tender plants should not have positions very near the ventilators, or those should be closed, otherwise the effect of the cold will seriously affect the plants. A cold night if followed by a hot day will not have any prejudicial effect upon the plants, as the heat will induce a circulation of the sap; but if the days are also cold and several of such succeed each other the sap becomes so sluggish as to tell disastrously upon the plants. In such weather very little water will be required at the roots, yet in the case of flowering plants sufficient water must be given to maintain the freshness of the flower, and what is given should be in the morning, at a temperature of 85° to 90°. It is advisable to employ a little fire heat in cold weather, presuming that the majority of the plants are from the stove, but if other plants in the structure are likely to suffer from the extra temperature it will be advisable to return the plants to their proper quarters in the stove.

The forwardest of autumn and winter-flowering plants, such as *Eranthemum pulchellum*, *Euphorbia jacquiniæflora*, *Poinsettias*, *Plumbago rosea*, *P. coccineum superbum*, *Thyrasanthus rutilans*, &c., will have filled the pots with roots. Instead of shifting the plants into larger pots afford weak liquid manure, keeping the plants near the glass in a low light house or pit, affording free ventilation by day to secure stout growth, and providing a little air at night, which has a decided ripening tendency; but on cold nights it is not desirable to admit air, as that would be a means of bringing off the lower leaves, which it is desirable to retain if possible, not only for the sake of appearance, but to afford the vigour essential to the size and quantity of the flowers. Stocks of the above or similar plants that were struck later will be in free growth, and must have every encouragement to complete it, but on no account allowing them to suffer for water at the roots.

Orchids.—In the East India house, now that the weather is cold and the sun less powerful, a closer atmosphere will be needed. In dull weather the moisture must be lessened, and the temperature maintained at 75° by day and 65° by night, syringing the blocks,

and well damping the house by three o'clock in the afternoon, employing the shading only to prevent the sun scorching the foliage. Every encouragement should be given to *Aërides*, *Phalenopsis*, *Saccolabiums*, *Vandas*, &c., as regards growth, any check being inimical to the growth of the leaves. See that the sphagnum in the pots or baskets of *Phalenopsis* does not become sodden, or the leaves soon show symptoms of distress. Dispense with shading altogether in the *Cattleya* house; they cannot have too much light to secure the thorough ripening of the pseudo-bulbs, upon which depends the flowering strongly. Some *Orchids*, as *Dendrobiums*, *Oncidiums*, *Cattleyas*, *Lælias*, *Barkerias*, and *Epidendrums*, &c., if not well ripened do not flower satisfactorily. Plants that are suspended should be over the pathway, or in such positions that the drip from them in watering and syringing does not fall upon those growing on the benches. *Calanthes* repot, employing a compost of turfy loam and peat in equal parts, adding a little old cow dung and some pieces of charcoal about the size of a hazel nut. Good drainage must be provided, keeping the plants about an inch below the rim of the pots. If the soil has become sour the plants should be shaken out carefully and the roots washed in tepid water. As flowers are becoming scarce every care should be taken of plants in bloom, keeping them from damp, those nearest the glass being most affected. *Cattleyas labiata*, *Harrisoni*, *maxima*, *crispa*, and the *guttata* type will flower from now up to autumn, and with *Odontogloss* will maintain an effective display.

TRADE CATALOGUES RECEIVED.

Lorenzo Racaud, Freule à la Puerta de Santa Encracia, Zaragoza.—*General Catalogue of Fruit and Ornamental Trees, Roses, &c.*

TO CORRESPONDENTS.

* * All correspondence should be directed either to "The Editors," or to "The Publisher." Letters addressed to Mr. Johnson or Dr. Hogg often remain unopened unavoidably. We request that no one will write privately to any of our correspondents, as doing so subjects them to unjustifiable trouble and expense.

IS THE STRAWBERRY A FRUIT OR A BERRY? (*H. D.*).—The Strawberry is neither a fruit nor a berry in the true botanical sense of these terms. The true fruit of the Strawberry are the small seeds that are found sprinkled on the outside of the fleshy receptacle, the latter being popularly termed a berry.

VINE LEAVES DISCOLOURED (*Amateur*).—The Vines producing them were extremely vigorous, and caused them to develop abnormally. Less sap is supplied to them now, and the excessive growth consequently is defective in colour.

WALTHAM CROSS VINE.—"A Gardener" wishes to have the opinions of practical men who have cultivated this Vine. We will publish any opinions communicated to us.

PEACH TREE DYING (*Senex*).—No one could decide which is the probable cause without seeing the tree.

FLOWER SEEDS AND ROOTS FOR TASMANIA (*E. R. P.*).—Of seeds send *Potentilla*, *Aquilegia*, *Antirrhinum*, *Campanula*, *Auricula*, *Bocconia*, *Carnation*, *Pink*, *Picotee*, *Canna*, *Cyclamen*, *Foxglove*, *Dianthus*, *Delphinium*, *Geum*, *Fernia*, *Fraxinella*, *Helianthus*, *Lathyrus*, *Pentstemon*, *Polyanthus*, *Giant Cowslip*, *Pyrethrum*, *Sweet William*, *Viola*, *Wallflower*—all fine hardy perennials, and most of them having several fine varieties which any good seedsman can supply. Of bulbs and dried roots we should send a collection of herbaceous Peonies, some *Ixias*, *Sparaxis*, *Tritomas*, *Tuberous Begonias*, *Gladioluses*, *Liliums*, *Irises*, *Anemones*, *Ranunculus*, *Narcissuses*, and *Dahlias*.

CULTURE OF *CLIANTHUS DAMPIERI* (*Australian*).—Sow the seed in February or March, using 3-inch pots, and for soil a rich mixture of turfy loam, leaf soil, silver sand, pounded charcoal, and a fair proportion of very fibrous peat if possible; if, however, the loam is thin and fibrous the peat may be dispensed with. Place one seed in the centre of each pot, plunging them in a lively bottom heat, lifting the pots up on the surface when the plants are visible and are growing freely. Water carefully. Repot as soon as the roots touch the sides of the pots, taking especial care to keep the bottom of the stem slightly above the surface, inattention to this causing the frequent losses of young seedlings. After repotting they may be taken to an intermediate house or vinery at work, and as the plants gain size and summer advances they may be removed to an ordinary greenhouse, where they should have plenty of light and air.

FIG TREE IN POTS (*A Young Gardener*).—After the first crop of fruit is gathered the trees should be thoroughly cleansed by syringing, and if need be sponging the leaves with a solution of soft soap, 2 ozs. to the gallon of water, affording water plentifully to the roots and syringing repeatedly, placing the trees in a warm part of the house with a view to accelerate the perfecting of the second crop, though to do so perfectly they should be placed in a separate structure, where with good treatment they will ripen a crop of fruit late in the season, which is very acceptable.

RAISING SARRACENIAS FROM SEED (*M. E. Walker*).—This seed soon loses its vitality, and should be sown as soon as it is received. Half fill a pan with broken potsherds, and fill nearly to the rim with a mixture of half fibrous peat and half sphagnum moss with a little silver sand. On this sow the seed, which leave uncovered, and lay a sheet of glass upon the top of the pan or use a bellglass, and plunge the pan to the rim in a lively bottom heat, such as Melons or Pines are growing in, taking care that it does not fall below 80°. The seed, if kept constantly moist, will germinate in about a month, and when the young plants have made a few roots pot them in similar compost in small pots.

TRANSPLANTING A LARGE CAMELLIA (*J. W.*).—The best time for transplanting your large Camellia is when the flowers fade, so as to have it settled in its new quarters before the new wood growth appears. As this quickly follows the fading of the flowers you must be prompt in order to give as little check as possible to the plant. Pay especial care to watering, syringing, and shading in the following summer.

PRUNING RHODODENDRONS (*White Rose*).—It is too late to prune Rhododendrons this year, it should be done immediately after the flowers fade. Wild Cherries are budded just like a Rose. No more time should be lost, as it is getting somewhat late; the operation may, however, be done now successfully.

GRAPES NOT KEEPING (*C. W.*).—Throw open the ventilators day and night now, and as autumn draws on and the weather becomes dull and damp close the ventilators at night and employ a little fire heat. Keep the bunches free from dripping moisture, let the air circulate freely among them, and the fruit will remain in excellent condition for two or three months.

SHRUBS FOR A FENCE NEAR LARGE TREES (*H. R. Willis*).—There are no better shrubs for your purpose than Hollies and Rhododendrons; both are handsome evergreens, and both answer well near and under large trees. Make a fence of strained iron wire outside your avenue with a permanent growing fence of common green Holly with a belt of Rhododendrons inside. If there are any spaces fully open to sun and air turn them to account for mixed groups of such choice shrubs as *Days*, *Laurestinus*, *Golden Holly*, *Ribes*, *Spiræas*, *Escallonia*, *Berberis*, *Arbutus*, *Daphnes*, *Skimmias*, *Perneytas*, *Lilacs*, *Weigelas*, *Box*, and *Portuguese Laurel*.

BLACK APHIS (*A. M.*).—We think, upon examination, you will find the insect now infesting your Roses and flower beds is not a thrips, but is an aphid. Sprinkle all infested growth with clear tobacco water of an evening after the sun is set, using 2 ozs. of tobacco to each gallon of water. Repeat this a few times at intervals of a couple of nights, and you will have no further trouble.

VINEGAR PLANT (*A. A. M.*).—The Vinegar Plant is a species of fungus which comes upon the surface of stale vinegar in the guise of a film. Now is an excellent time to obtain it by leaving a little vinegar in the bottom of a cruet or small bottle and throwing in a little coarse brown sugar. The film will soon make its appearance, and must remain undisturbed till it becomes sufficiently thick to bear removal. Dissolve half a pound of coarse brown sugar and half a pound of treacle in two quarts of boiling water, and when it is cool put the plant into it. The plant will float and soon cover the entire surface, and the liquor will become vinegar in about two months. It answers best in a jar with a lid to exclude air, and the jar should stand upon a shelf in the kitchen or in a warm cupboard. The vinegar is strained and bottled when ready, and the entire plant or portions of it again used for making a fresh supply.

SUMMER MANAGEMENT OF *LIBONIA FLORIBUNDA* (*Idem*).—After *Libonias* have done blooming in spring they should be gradually hardened, so that by the end of May they may be pruned, shaken out of the pots, and planted for the summer in an open border. Here they make a strong bushy growth, and are taken up and repotted about the third week in September, or a little earlier in the north, placed in a close pit or frame for a week or two, and then taken to their winter quarters in the greenhouse. The answer to "Australian" contains the information you require about *Clianthus*.

TRAINING MARECHAL NIEL ROSE (*W. W. B.*).—We do not quite understand your sketch, but presume that A is the top and B the bottom wire, the wires being stretched horizontally one above the other like those of a fence. If you stop the shoot when it reaches the wire A we do not think it would put forth laterals to furnish the lower wires; it would certainly not do so this season, but would simply produce shoots at the top. So far as we can understand the position of the plant and wires we are inclined to recommend that the shoot grow this season without being stopped. We would then depress it considerably before fresh growth is made in the spring—in, indeed, would bring it to a horizontal position along the lowermost wire, and would shorten it then at the point you propose, stopping it now. The shoot being horizontal the buds would break regularly, and would supply laterals for each wire, which could be occupied by placing the parent shoot in the vertical position required. By allowing the plant to grow freely this year you will encourage root-action, which will induce a correspondingly strong growth next year. If, however, the plant is very strong you may stop it now about the wire C, so as to produce laterals for furnishing C, D, and E this year, leaving wires B and A to be occupied next year. It all depends on the strength and vigour of the plant as to which is the preferable plan to adopt. Your great point to aim at is to have the growth on wire E in advance of that on the wires above it, or your trellis will not become covered at the bottom. The easiest and perhaps the quickest way of covering the space you require would be to let the shoot grow unchecked, then train it along the bottom wire, and from it train shoots vertically across the wires to the top.

DESTROYING RED SPIDER (*M. G. M.*).—The mixture is not neutralised by the lime sinking to the bottom; it usually sinks, a film rising to the surface. The quantity of lime you use is not material.

BULLOCKS' BLOOD FOR ROSES (*Idem*).—Dilute one gallon of blood with seven gallons of water, and apply to the roots when the flower buds are showing.

SOWING CARNATION SEED (*A. A. M.*).—The seed may be sown now, but we doubt if the plants will flower next year; they will, however, make fine plants for flowering in 1880. Sow now in rich light soil, either in pans or in the open border, and keep the soil moist and shaded until the seedlings appear, and then keep them well protected from slugs. *Dianthus Heddergigi*, if sown about the middle of the present month and the plants are protected during the winter, flowers early in the summer following; but seed is usually sown in the spring, the plants flowering the same season.

MUSHROOM BED NOT PRODUCING (*Idem*).—Either the spawn was not good when inserted in the bed, or the bed was not in the right condition for the spreading of the mycelium. It was either too hot or too cold, too wet or too dry. You must make a new bed and insert fresh spawn. You will find full instructions in "Work for the Week" in the present number. The withered flower and leaf appear to be those of a *Lantana*.

CUTTING MELONS (*Inquirer*).—As soon as the fruit commences cracking round the stalk it may be cut. If the aroma is powerful the fruit may be severed from the plant even if no cracking is perceptible.

NAMES OF PLANTS (*W. Crick*).—1, *Yucca filamentosa*; 2, *Lycosteria formosa*; 3 is, we think, a *Cornus*, and 4 a *Mahonia*, probably *M. japonica*.

We do not name plants from leaves only. (*J. W. Collins*).—1, *Veronica Hendersoni*; 2, *Euonymus japonicus* fol. aur. variegatis. (*Arthur Miles*).—*Lathyrus sylvestris*.

THE HOME FARM:

POULTRY, PIGEON, AND BEE CHRONICLE.

HARVESTING OF BARLEY.

WE have made the harvesting of wheat, oats, and barley the subject for separate articles, as there are certain circumstances in connection with the securing of each of these crops which differ in some material points. Although each of them stands in an important position connected with the profitable management of the home farm, yet they have a different value, not only for use as grain produce, but also for straw and fodder purposes. In the harvesting of winter barley, which is a strong and robust kind of grain with a short thickset ear, and coming ripe as it does very early and before the wheat crop, it does not require different management in harvesting from the wheat crop, and there is usually but little difficulty in securing a favourable harvest for it, especially as the grain is only required for meal purposes or to sow in admixture with fodder crops like vetches. The straw, also, is not generally used for fodder, it being long and strong, and is best adapted for all the purposes to which wheat straw is applied, including thatching, for which purpose it is very wiry and durable when harvested with care and thrashed by one of Clayton & Shuttleworth's machines, which deliver the straw from the machine as straight and uninjured as reeds. The usual sorts of barley used as a spring-sown crop for the best purposes may be said to consist only of two distinctive varieties, or rather having two separate objects in view, which refer to soil as well as the purposes to which the grain is applied.

The strong coarse-growing barleys, such as the Red-bearded American and the Long-eared Nottingham, both of which are well adapted for high cultivation and deep alluvial soils, may be usually harvested with less trouble and care than the Golden Melon and Chevalier varieties. The two former kinds being long and stiff in the straw may be the more easily tied into sheaves after being cut with the reaping machine; but the two latter sorts, which give the best samples of malting grain grown in the kingdom, are chiefly grown upon the light and cold soils, are short and soft in the straw, and the more easily become laid and twisted about, making it difficult to cut by the reaper and more difficult still to tie into sheaves. It is, however, desirable for all sorts of barley to be tied into sheaves and set up in stooks if clean and straight-grown, more especially in a showery season; because when cut and left on the ground when there is clover amongst the crop, it being then all exposed to alternate rain and sunshine, it inevitably becomes stained and discoloured; whereas when once it is cut and tied in the dry and properly shocked, taking care to set the sheaves well out at the bottom and the tops carefully settled in together, it will endure a great succession and long continuance of adverse weather without serious injury. Only the outside of the sheaves is then exposed, and consequently only a portion of the grain will be stained; it may, therefore, be ultimately secured as a malting sample. The only objection we have ever found to tying barley and setting it up in shock is that it kills the clover. Now in the case of an oat crop with clover the shocks of oats may be moved every few days if the weather is bad without serious injury to the grain, and thus relieve the clover seedlings. Not so with barley, because in a showery season its removal would be fatal to the sample as malting grain; on the other hand, if it remains in shock without removal until carted to rick it kills the young clover plants under the shocks. It thus becomes a question of cropping—whether it is desirable to sow clover in barley as a rule. We think not, and that the barley intended to furnish malting grain should be sown without clover seeds with it. We have another

strong objection to clover in barley, because we think the growth of the two crops together interferes with the plumpness of the grain, and that in the mixed soils of the country the barley would produce a much better malting quality in the absence of the clover seeds. We have no doubt that this opinion is shared by the majority of the practical farmers; but, unfortunately, the conditions of farming as drawn in the leases upon various estates compel the tenant to sow clover and grass seeds in the Lent corn. We also find that on many estates in the hands of practical land agents that such matters are gaining more attention, being altered by giving more liberty of action to the tenant as to the mode of cropping, not only in this but in various other important respects.

The state in which the barley crop is found at the commencement of harvest is very much affected by the previous crop. For instance, when barley is grown after roots fed off by sheep the crop will be generally very uneven, for where the stock feed the roots upon the land in wet weather the barley crop is sure to suffer and grow with great irregularity. The crop will be found to be best in bulk and sample, where the roots had been fed in dry and favourable weather, and, unfortunately, the best and worst parts of the produce cannot often be harvested separately. In those cases where a line can be drawn so as to cut and tie the best portion of the crop and cart it to rick or barn separately, it is advisable to do so, as sometimes the best malting barley would fetch as much as 15s. per quarter more than that only fit for meal purposes.

The time of cutting barley is of far more consequence than other grain, for whereas wheat and oats are benefited by early cutting, on the other hand barley should (if malting grain is required) never be cut until both straw and corn are dead ripe. This is usually indicated by the ears hanging down, and the grain being not only hard but the skin shrivelled on the back of the grain. If it is cut early the grain becomes steely and only adapted for grinding purposes. The question of straw of barley is only a secondary matter, as we value it but little for feeding purposes unless it is short in growth with a quantity of clover in it, well secured without rain, as we prefer wheat or oat straw for chaff-cutting for horses and cattle. The use of the reaping machine with self-binder is of less use for barley than for other grain, as it seldom is delivered straight enough to tie in good-shaped sheaves; it is more likely to be in unsightly bundles. Nor can we recommend the wire-tying for barley, as the wire interferes sadly with the feeding value of the straw. Much of the barley is this year very much laid and twisted, so that it cannot be cut with the scythe without cutting off too many ears. We, therefore, in some cases must resort to the fagging hook as the best way of saving the most corn and having the grips in the best order for tying. Many persons object to the tying of barley because of the extra expense, but it is only in the payment for cutting and tying, all the work afterwards being done not only at less cost but with much greater celerity. The loading and carting to rick takes less time; the rick is better and quicker made, particularly if made round; after the rick is made it takes less thatch, does not require to be whipped outside, the butts of the sheaves only require to be shaved close. Again, when it is thrashed it is much less work to haul to the machine than loose corn, and much more quickly thrashed and disposed of. The question of usage of waggons or carts is still a disputed point amongst the farmers; they say waggons are best on hillsides. They probably are better than the carts with head and tail ladders; but in our opinion nothing is so good in carting corn of any sort as the low-set harvest frames or skeleton carts, as they are easier to load and unload, and not so likely for the loads to fall off going to and fro.

WORK ON THE HOME FARM.

Horse Labour will consist principally of carting the crops of pulse, grain, and second-cutting clover to stack; there will be, of course, short intervals of tillage, such as preparing the land for stubble turnips, mustard, or rape, as may be required, according to soil and the rotation of management. We will, however, take this

occasion of referring to other animal power for tillage of the land, and allude to the working of oxen, although it is notorious that steam power on the larger farms occupies the attention of farmers entirely as supplementary power to that of horses, and very properly so. We can well recollect the time in our business when steam power was not available as it is at present; we cannot therefore entirely ignore the use of oxen as a supplementary power in tillage in the autumn portion of the year. This brings us to the point of how the extra power can best be obtained, as there are certain circumstances existing in almost every district which may prevent the application of steam power, with the customary advantages attaching to it. In such cases we therefore recommend that oxen may be used with advantage. The best sort of animals for working on the land are the Sussex and North Devon breeds; sometimes, however, we have known Shorthorns used, but the Sussex breeds are strong, powerful, and good-tempered animals, easily broken in and inured to work. The same may be said of the Devons, except that they are not so powerful; but the Shorthorns are not always to be depended upon as to temper, besides which they are more commonly fattened at an early age.

The plan we propose is to purchase on the eve of harvest, say about July 20th, three oxen which have been broken to the collar for every 100 acres of arable land a farm may contain, and continue them in work attached to the scarifier during the whole time of harvest after the first clearance of corn, and until the time for wheat-sowing arrives, up to which time, the horses of the farm having assisted the oxen in autumn tillage, the work will be in a forward state, and the oxen will then assist the horses in helping forward the wheat season. After the wheat-sowing is completed the oxen and horses may join in the work of fallow-ploughing all the land which had been previously autumn-tilled and intended for root crops the following season. The work will then be forward enough to dispense with the services of one horse upon every 100 acres, or in other words to employ three horses instead of four as usual. The result of this scheme of cultivation is that except by the use of steam power the land will be more forward than by any other means, and at a less cost than by employing the usual number of horses during the year.

To make this plan profitable we propose that the oxen shall be fed during the period of work, say four months, at the same cost in food as the horses; three oxen will then cost the same in keeping as one horse for the twelve months, and when fed in this liberal manner they will not only be strong in their work but will improve in value from 20s. to 30s. each during the four months, whereas the horse during the twelve months would have depreciated in value from £3 10s. to £4. The advantages to be obtained from this mode of proceeding are obvious. The root land will be all tilled in the autumn, and done at moderate cost; and when the oxen have done the work assigned them they will be in improved condition, and will pay as much as any steers that can be bought, to be put into the boxes to fatten off at the end of twenty-one weeks from the time of completing the work of tillage.

Hand Labour will now be fully employed in the harvest field and stacking the corn; there may, however, be intervals of damp weather when the men may be employed in hoeing late turnips and the women in singling the roots behind the hoers. Hedge and border trimming will also be done at odd times, when harvest work is delayed. The shepherd can seldom find time to do any harvest work, as he will usually be fully employed with his flock in various ways. The newly-purchased lambs will have to be shorn before the end of the month, and if this to some persons is a new idea we recommend them from our own experience to try one half of the lambs shorn and the other half remaining in their wool. Let them all be kept together and fed alike until February or March, and sold at the same time; it will then prove the advantage or otherwise of shearing the lambs. The herdsman must now look to his yearling-off heifers, and have a well-bred young bull running with them in the meadows every day, in order that they may bring their first calves in the May month. Whilst the heifers are feeding the meadows at daytime, it is, however, a much safer plan to remove them at night time to lie in a dry pasture or on to arable lea ground, as they are very apt to suffer from "quarter evil" when the meadows are situated below the fog level if allowed to remain at night time, because we often get a white frost in such meadows.

CHESHUNT AND WALTHAM ABBEY POULTRY SHOW.

THIS was held on August 8th, when the following prizes were awarded:—

POULTRY—**DORKINGS**.—*Cock*.—1, E. Snell. 2, A. J. Page. *Hen*.—1, H. C. Fellowes. 2, E. Snell. **COCHINS**.—*Cock*.—Cup and 2, Lady Gwydyr. 3, Mrs. Breeze. *Hen*.—1 and 2, Lady Gwydyr. 3, A. Todd. **BRAHMAS**.—*Dark*.—*Cock*.—1, L. C. C. R. Norris. 2, Mrs. Breeze. *Hen*.—1, L. C. C. R. Norris. 2, Dr. Holmes. *Light*.—*Cock*.—1, P. Haines. 2, Lady Gwydyr. *Hen*.—1, P. Haines. 2, W. Howard. 3, Lady Gwydyr. **SPANISH**.—*Cock*.—1, R. Newbitt. 2, Schelp. *Hen*.—1, J. Woods. 2, W. D. Frosser. **GAME**.—*Black or Brown Red*.—*Cock*.—1, H. E. Martin. 2, J. Colgrove. *Hen*.—1, E. Winwood. 2, T. D. B. Rawlins. *Any other variety*.—1, J. Colgrove. 2, H. E. Martin. **HAMBURGS**.—*Golden-spangled*.—1, S. R. Harris. 2, J. Ashworth. *Silver-spangled*.—1, J. Ashworth. 2, R. Barnes. 3, R. A. Pratt.

JUDGES.—*Poultry*: Mr. J. Long, Hitchin. *Pigeons*: Mr. P. H. Jones, Fulham.

AN INTERNATIONAL POULTRY SHOW.

It is often said, and we believe with much truth, that we are apt in England to "lock the stable door after the horse has been stolen." Any public, especially any international undertaking, is sure with us to be got up on a grand scale, and as sure to be carried out in no niggardly spirit; still it very frequently happens that many small matters of detail, which may in themselves seem trivial and unimportant, are not duly considered beforehand, and consequently some undertaking which apparently goes off with *éclat* does not prove really satisfactory to those particularly and intimately interested in it; and behind the scenes it is said, "What a pity it is that such and such a matter was not before thought of, for had it been otherwise the success of the affair might have been real, and not seeming only." This has been the case in international meetings of various kinds where courtesy prevented exposure. All the world knows by this time that a grand agricultural show is to be held in London next year, and that there is every prospect of its being an international one; it is also rumoured, and we have reason to think the rumours not unfounded, that a show of poultry will be included in the programme. This being the case we shall endeavour beforehand, and not when it is too late, to point out some of the conditions which to us appear essential for the success of an international show. It would be affectation to conceal the fact that most of those are suggested to us by the experience of the late Paris Show. That that Show was not a success and was not well managed can no longer be a secret. Indignant letters of complaint about it daily reach us, and the columns of one of our contemporaries have been filled with them. As far as we know the most successful English exhibitors, who might naturally be biassed in its favour, were not satisfied, and would gladly have sacrificed all honours and prizes not to have sent. The English judges were highly annoyed at many things both during the Show and since; and, lastly, the loss of birds through death by starvation and fatigue on the return journey seems to have been simply enormous. Did exhibitions ordinarily entail a tithe of this suffering on the poor creatures exhibited nothing would ever induce us again to exhibit a living thing; and had the whole taken place on this side of the Channel there would have been a host of defendants in the Courts, with the Society for the Prevention of Cruelty to Animals as plaintiffs. All this can now only be regretted, not avoided; timely warning, however, and reasonable forethought may prevent the chance of such a disaster in this country.

We will begin with the very beginning—viz., the schedule of prizes. A schedule for a show in which foreigners are invited to compete should not be drawn up without consultation with eminent fanciers of the nations most likely to enter. Nations have their tastes and prejudices as well as individuals, and if these are not previously taken into consideration differences or disappointment will infallibly ensue. It would be truly disheartening and unsatisfactory to a Frenchman or a Belgian to be told "Your bird is in its way by far the finest in the class, but it is not quite in accordance with English taste, and consequently it is not noticed." Where national tastes are utterly different, or where the same names signify birds with totally different characteristics in different countries, matters can alone be satisfactorily arranged by previous consultation between connoisseurs of the various nations to be represented. Then as to the translation of the schedule when once drawn up, it is absolutely necessary that this should be done by people who have some slight special knowledge of the subject. For instance, in the Paris schedule, or rather its English translation, a class was devoted to Hamburgs. Naturally English fanciers sent specimens of all five kinds recognised here as Hamburgs; but in French Hamburgs include but two of these five, while two others should have been in the Any-other-class limbo, and the fifth, Blacks, should not have been sent at all, at least if their owners did not wish to hear their pets run down as mongrels.

Again, the question of judges is an important one. It seems but natural that in an international show various nations should be represented among those who award the prizes. Still there are practically great difficulties in carrying out this theory from the deadlock which occurs where national tastes are opposed; and

even supposing the question to be decided in the affirmative, a further doubt arises as to whether particular classes should be given to the foreign judges, or whether they should be on a mixed board with those of the country. Much may be said on both sides; but whichever course, however, be adopted, we should strongly advise that the names of those to adjudicate upon each class, or the exact composition of any board of judges, should in fairness be announced before the entries close.

Next to the question of the schedule and of the judges comes that of the conveyance of the birds to and from the show and of their treatment during it. Whenever any general invitation is given to foreigners, as a matter of national courtesy every effort should be made to render their journey or the transit of their property as easy as possible. The Paris Exhibition being a State affair, such matters were probably more easy to arrange than they would be when any private society, however eminent, invited competition. Still, if the cost of foreign exhibits cannot be entirely defrayed, at least it might be so arranged as to occasion no unreasonable cost and as little trouble as possible to the exhibitors. English exhibitors were struck by the liberality of the provision in the French schedule that all specimens should be conveyed free of cost both ways between the frontier and the Exhibition; but in practice this regulation proved most delusive, for firstly the railway officials were so ignorant of it that some exhibitors had notwithstanding to pay high rates, and also the free pass was alone for such trains that the unfortunate birds and their attendants had to start from London one whole week before the Show began, and the return journey was performed in an equally leisurely fashion, so that to our own knowledge dozens of beautiful birds succumbed on it to hunger and fatigue, or directly after it to exhaustion. It would be easy for whatever society wishes to have a really international meeting to arrange special times at which all birds should be sent to two or three named foreign ports, and to send men to such ports to receive them and bring them over with all expedition.

Then as to their treatment while at the show. Not only should this be scrupulously careful, but it should be made perfectly clear to exhibitors beforehand what food and accommodation will be provided. If the French, or Italian, or Belgian mode of feeding is different to our own let this be discovered, and let foreign exhibitors be invited to send proper food with their birds. On the arrival of the English birds in Paris not only was no food at all procurable, but no drinking vessels were provided, and some of the English attendants had to go out to buy the latter.

These are broadly some of the most obvious and important considerations for the promoters of any international show. We do not here advocate the holding of such a show, but if one be undertaken, as seems possible, for our national credit's sake let it be well carried out. We have for weeks, amid many reports which annoyed and astonished us, refrained from criticising in a captious manner the late Paris arrangements; but at least their utter breakdown in a country generally celebrated for its organisation may serve as a grave warning to us as a nation to attempt nothing of the kind without previously counting the cost, and if we do attempt it to leave no matters of detail, however seemingly unimportant, to the chance of the hour.—C.

VARIETIES.

SOME substantial donations recently made to the fund for holding a great agricultural Exhibition in London next year bring the total amount up to £7000. The Show is to be under the auspices of the Royal Agricultural Society, and under the presidency of H.R.H. the Prince of Wales.

— FOR the Winchester Poultry, Dog, and Flower Show, on the 14th and 15th inst., there are entries of Pigeons and poultry 350, and of dogs 180.

— WE have for some time been surprised to see no advertisement of an Oxford Poultry and Pigeon Show this year. We regret to learn that there is much chance of this popular meeting falling through from the unwillingness of the members of the Town Council to allow it to be held, as previously, in the municipal buildings.

— AUGUST 12th is, says the *Agricultural Gazette*, about the last day of the year upon which turnips may be sown with a fair prospect of succeeding. To persist in sowing later entails a considerable expense per acre in seed, labour, and manure, and the result is often most miserable. We can scarcely hope to see the young turnips above the surface before the 20th of the month, and before they are six weeks old cold and even frosty nights may sadly interfere with their development. Another objection to late sowing is often to be found in the condition of the land, for in most cases it is advisable to clean stubbles from couch rather than to hastily plant them with a catch crop, such as late turnips. Certainly in seasons such as 1868, 1870, and 1874, when roots have failed, no time should be lost in occupying corn stubbles with late turnips, and we would be loth to fix a date at which to discontinue sowing. But the present season has been peculiarly kind to roots. There is a good prospect of winter keep, not only in the

form of Swedes and turnips, but also in hay, and the better policy will be that of cleansing land from weeds rather than attempting to raise a still greater quantity of fodder.

— THE storms of the last few days, says the *Farmers' Gazette*, although beneficial to the pastures and root crops, which very much required rain, have kept the harvest work back, and we fear in many districts have injured the crops. Should the heavy rains continue the consequences will be serious, but should fine weather now make its appearance, perhaps nearly as much good as harm will have been caused. There is every prospect of a good root crop, and, combined with the abundant and well-got hay crop, the prospect for winter keep is exceedingly favourable. We only now require a month's fine weather for harvest work, and the agricultural year, we believe, will be completed in a satisfactory manner. Although at one time the prospect was gloomy and the situation, in the opinion of some, almost desperate, it has so much improved that, with the return of fine weather, it will probably prove the best season we have experienced for several years past.

— EXTRAORDINARY PIGEON FLIGHT FROM READING TO BRUSSELS.—Mr. J. W. Barker, of 18, Rupert Street, New Town, sends us, says the *Reading Mercury*, particulars of an extraordinary Pigeon fly from Reading to Brussels. He writes:—In Belgium Pigeon flying is, as is well known, a national pastime, and one of the most successful at this amusement is Mr. Barker, an Englishman. Last week he sent me some of his young Pigeons, and with them sent five adults to be liberated to fly back to Brussels. They reached me at Reading quite safely about mid-day on Thursday, the 25th ult., and in the evening were minutely inspected by several members of the Reading Ornithological Society, and each bird marked with the Society's official stamp. On Friday morning at ten o'clock at the rear of the biscuit factory I gave the five birds their liberty in the presence of several friends. On leaving the basket they immediately dashed away without any hesitation, and at a great speed, in a straight line towards home. In the evening I received a telegram stating that all the birds were home before four o'clock, and giving the stamp on their wings. What makes this flight the more extraordinary is the fact that the birds had been tossed only twice in this direction before coming to Reading, and this was at Poperinghe, about forty miles this side at Brussels; they have, however, had considerable experience in other directions. The birds that accomplished this surprising performance have been returned to me from Brussels.

HARVEST FROM FIRST-CROSS ITALIANS IN STEWARTON HIVES.

A PARISH MINISTER, a careful apiarist of our neighbourhood, writes as follows on 7th inst.:—"I write to say that I have now taken off 309 lbs. of first-class super honey in all, and that I have still ten boxes to remove. I estimate the contents of these boxes as at least 120 lbs., so that my super harvest will amount to 430 lbs. in all from eight hives. I shall besides have a great deal of run honey in September. You have a right to know this, for it is certainly to your very kind instructions I am indebted for my success. Two of my large swarms (first-cross) flew away during the summer. Mrs. F. has got the one, and it is her best stock for next year, and I saw the other in a large old tree yesterday at S—, near K—. The first-crosses are undoubtedly the bees to breed; but I see, now that the season is dull, that the black bees are doing nothing, but that wherever there is Ligurian blood at all the hive is active and adding to its stores."

After such a deplorable season as last good returns are cheering. Although the present hot summer will place the honey yield above an average, still I am afraid ultimate returns will not rival the great honey season of 1868, nor yet that late but wonderful bee year 1876.—A REXFREWSHIRE BEE-KEEPER.

THE EXHIBITION OF BEES.

SOUTH KENSINGTON, AUGUST 6TH.

ALL honour is due to those who are so strenuously endeavouring to introduce the modern and humane system of treating the industrious bee, and who in spite of prejudice, obstinacy, and ignorance are year by year bringing forward the results of their labours. The British Bee-keepers' Association has already held its exhibitions at the Crystal Palace and Alexandra Park, and this year it has brought together the bees, bee furniture, and all the various items connected with them at South Kensington under the distinguished patronage of a lady who is ever ready to help forward in every good work, whether it be for the benefit of her fellow creatures or for the good of the animal creation—the Baroness Burdett Coutts. The day was somewhat an unfortunate fixture, for as the railway companies delivered no goods on the Monday, being bank holiday, many of the exhibits were very late, and consequently the work of judging, &c., could not be proceeded with as early as had been intended; but there was a great muster of apiarists from all parts, much enthusiasm was displayed, and much useful information given. Instead, however, of going into

minute details of each department as to who gained prizes, &c., we prefer giving a few general observations as to the most salient points of the Exhibition.

We were particularly struck with the almost universal adoption of modern bar-frame hives. Not only has the straw skep disappeared from the apirians' catalogue, but the modifications of it, as in the old Woodbury, have also vanished, and wood is now the universal material of which hives are made. Improvements on these are taking place every year, and in the Stewarton, the Philadelphia (Messrs. Neighbour), the Standard (Abbott), Lee's and others we seem to have attained all that is needed. Each year has witnessed some improvement, but after all Abbott's, which again took the first prize, leaves nothing to be desired. The wire pin to the boxes has been superseded by the broad shoulder, making it much firmer, and various internal improvements have been added. An ingenious plan of shutting off the bees, so as to prevent swarming, by a zinc perforated frame seemed to be very ingenious, for a very general complaint this year was that the bees would swarm. Very few large supers were exhibited, and super honey was by no means plentiful; and this is one of the things which confirm cottagers in their prejudices.

Another prominent point was the universal use of the quilt. When Mr. Abbott introduced it some years ago it was denounced by some influential bee-masters as an American invention of no use whatever, yet now we find it in nearly every hive, and experience has only confirmed the good opinion expressed concerning it and suggested improvements. Formerly a piece of carpeting was used, but it was found that the bees disliked the woollen material and picked it to pieces, making a mess with it, as they will do with tape if the combs be tied in with it at any time. Hence the best fabric for putting next to the bars is the hair cloth which is used for covering the strainers used in kitchens. It is hard and yet porous. On this may be placed carpeting or any other woollen material, such as house flannel, which will keep the hives warm during the winter. It is very convenient, too, for examining the hives at any time; and when they have to be fed a hole is made in the centre, on which the stand for holding the feeding bottle is placed.

Then again there was a very general use of the zinc adapters, by which when supers are placed on the hives the bees have access to them through the perforations in the zinc, which are of such a size that the workers can alone get up, the drones and the queen being unable to get through. Latterly the oblong perforations seem to be more in vogue, but they hardly seem to be so effective as the round. There seems to be more possibility of the queen and drones getting through, and moreover it does not rub off the pollen as the round does; but it must be noted that it does sometimes happen that the bees will not return, and I have found in one of my supers this year a good quantity of dead bees. Hence some apirians adopt the plan of cutting a small hole in the super to let the bees go out if they like and carry out their dead. Why this should happen we are at a loss to conjecture, for in other hives they work up and down most freely and seem to find no difficulty; but we know how stupidly bees when they get into a greenhouse will persist in flying up and down the glass and eventually killing themselves, although the sash in the very next division may be wide open; but these exceptional cases do not detract from the great usefulness of the zinc adapter.

Equally general is the use now of the sectional supers; these were shown by Messrs. Abbott, Lee, and Horne, Mr. Lee taking the prize for the best and cheapest. These supers are very valuable, containing from 1 lb. to 2 lbs. of comb each, and so presenting comb honey in a saleable form to the public, and thus meeting one of the great drawbacks to bee-farming in this country. There is a vast quantity of trash imported under the name of Narbonne, Californian, and other honey, of which a great portion is little better than syrup, and this is sold so cheaply that home-made honey is not easily got rid of. When people go to Switzerland they are delighted to find *miel en rayon* on the breakfast table, but when they return to England honey in the comb is looked upon as "bilious," or something of that kind, and so refused. Why do not our large pauper schools use it for the children instead of butter? and if some eminent physician would only act as a bell wether and proclaim honey in the comb to be an excellent thing for the complexion the family would soon follow, and we should find it then on every breakfast table throughout the country. These sectional supers are excellent for the purpose of sale. Many persons would hesitate to buy supers of 20 lbs. or 30 lbs., but these handy little boxes are just the thing to take home without any bother, and I have no doubt they are destined to supersede all others.

It was noticeable, too, that all the toy adjuncts of bee-keeping have vanished. There are now no elaborate bee houses with first, second, and third storeys; no pagoda-like structures suggestive of the very essence of cockneyism. All is now utilitarian, but not at the expense of neatness. Nothing can be neater than the hives of Messrs. Abbott, Lee, and others, but it is at once seen that the object is use not ornament; and as they are now made with moveable covers each one can stand by itself protected from the weather, and thus not so exposed to the depredations of wax eating spiders, mice, &c., as when they are in houses.

In the tent the manipulation of bees according to the new method was fully explained by Mr. John Hunter, while Mr. Abbott and other bee-masters showed how easily bees were managed. Driving, uniting, transferring, and all the various methods adopted by modern bee-masters were shown, much to the astonishment of the visitors, many of whom evidently seemed to think that there was some special means adopted to prevent the bees from stinging. Ligurian and British bees were also shown, and an admirable observatory hive by Mr. Brice Wilson attracted general observation. There were two exhibits deserving especial notice; one a Portuguese hive, exhibited by the Rev. J. F. Scott, an experienced bee-master, and which is of the same kind as that described by Virgil in the "Georgics," and some honeycomb made by bees in the Strand—partly artificially fed, partly gathered from the flowers on the Embankment. Altogether the Show was a great success, so much so that it is, we believe, in contemplation to repeat it next year in the same place. We should be sorry to add a word to damp the ardour of our friends, but as yet do not see that we have made any inroad on the cottagers, who do not appear to have abandoned the old straw skep and the sulphur pit; as yet it is the few who have seen the advantage of the modern system.

DRIVEN BEES AND SUGAR-FED STOCKS.

"H. W. S." asks, "When is the best time to drive the bees of old stocks with a view to take their honey?" As many other correspondents have been of late asking questions on the subject of driving bees it may be well if we take up the subject in a general way, and go over the ground in these notes.

For ten years we have not lost an opportunity of commending sugar-fed stocks of bees, and now we have the satisfaction of knowing that our commendations have induced many working men to gather together the condemned bees of their neighbourhoods by first driving and hiving them, and then feeding them into stocks. Many of the men who thus commenced bee-keeping are in the van of the advancing hosts of British bee-keepers. Experience, which is the shortest way to knowledge and success, has put them in the front rank of practical apirians and made them what they are. Many of our readers who have not yet driven bees, or united swarms, or fed them into stocks, have only to begin with a will, for all who do so succeed beyond their expectations.

In answer to "H. W. S.," who wants to know the best time to drive bees from old stocks, we have to say that nobody can answer the question with any degree of certainty, for seasons and districts differ much, as well as systems of management. For instance, bees on the moors in August gather honey fast and set thousands of eggs, whereas those not on the heather generally eat more honey than they gather in August, kill their drones, and cease to breed for the season. If honey is the first and only consideration the best time to drive bees is when they begin to eat more honey than they gather—in other words, when their hives become lighter. Bees on the clover, generally speaking, begin to lose weight early in August, and on the moors early in September. But the question of brood and its condition in hives has to be considered, as it is important, for the bees only that are hatched in autumn survive the winter, and early driving may destroy much unhatched brood. When it is meant to feed the driven bees into stocks it should be known and well understood that early driving is advantageous to the swarms, for in August they build combs faster and breed more readily and abundantly than they do in September and October. It is easy to get driven bees by artificial feeding to build combs and fill them with brood in the warm month of August when pollen is abundant. As autumn advances the disposition to build combs and hatch brood becomes less, and hence the greater difficulty of creating good stocks late in the season. Bee-keepers, however, possessing a fair share of shift and thrift can surmount the greatest difficulties of management. If hives marked for honey be found full of bees and brood at the commencement of August four-fifths of the bees could be driven with the queens from each of them into empty hives, and one-fifth left in them to hatch the brood; thus stocks could be created in August, and the brood of the honey hives hatched by the remaining bees. The removal of the swarms from the honey hives would save much of the honey from being eaten, for bees consume a great deal in August. In our practice we do not follow this plan, though we are miserly in our treatment of autumn brood. In taking honey we generally drive several hives at the same time, and drive the bees wholly out of the honey hives. All their combs with brood in them are speedily and carefully cut out and placed in an inverted empty hive, some on their edges, some on their broadsides, some one way, and some another, but kept asunder by little bits of wood, so that bees can move and be hatched amongst them; then we throw a swarm or half a swarm amongst them to hatch the brood, and thus a large and invaluable stock of young bees is got from refuse combs to enrich stocks for winter and spring; a board, of course, is placed over the combs and bees in the inverted hive till all the brood is hatched. The reader will see at once that by this treatment there is no destruction of life, no

sacrifice of brood, and no waste of honey—everything is husbanded to the greatest advantage; but the time of driving bees or doing this work must be left to the bee-keeper himself, and be determined by circumstances.

Now a word about sugar-fed stocks. Some fifty years ago I was interested by an experiment with a swarm driven from a straw hive in the month of September. It was put into an empty hive and fed on treacle alone—not golden syrup but black molasses. It half filled the hive with combs, kept its bees well through the winter, and became a good stock. The knowledge of the discovery that bees can build combs rapidly from sugar and be healthy and live to a good old age while eating nothing else, cannot be too widely circulated. The experience of every season gives additional proof of the value of sugar-fed stocks. We prefer them to swarm hives or old stocks. Their combs are young and sweet, and while being erected the centre ones are filled with brood, and thus almost every cell in six or seven of the centre combs yields a young bee in August or September. We invariably find on examination of our stocks in February or March that those treated by sugar-feeding in the preceding autumn are comparatively strong in population. They thrive better, too, than older ones, for their combs are not clogged and cloyed with pollen. We leave it to the doctors to tell us how it is that bees gather in Great Britain more pollen than they require, but we notice the fact that the superabundance found in old combs is a great obstruction to the bees themselves and a great nuisance to bee-masters. We have seen more than three cells out of five in the centres of hives rendered useless by pollen stored in them. From another cause, too, old combs are objectionable. Their cell walls become thick by the skins or pellicles which young bees leave behind them. Every bee hatched in a cell leaves a coat behind it, which becomes a part of the cell. Only fancy ten such coats being left in every open cell in the centre of hives every two years, and that is a moderate calculation of five hatches of brood every year.

Much is being said by a certain school of apiarians about the wisdom and economy of preserving old combs and saving the bees from building new ones. We honestly question both the wisdom and the economy of such practices. Take an empty 16-inch bar-frame hive and put a swarm of thirty thousand bees (or 6 lbs. weight) into it. Give it 5s. worth of sugar, and the bees will fill it with combs and brood. Forget the 10 or 20 lbs. of honey in the combs whence the bees were taken, and compare this sugar-fed stock with any swarm or stock hive near it. Though it cost only 5s. to create it, an experienced and competent judge would probably value it at 10s. more than any bar-frames filled in the usual way.

This morning a working man came from Partington, a village five miles distant, to see my bees. Some hives were turned up for him to see, amongst these three sugar-fed stocks in course of creation, which greatly astonished him. He had never seen or heard of such a thing before. He said he had four hives, and he left me saying if he treated his bees in that manner he would get 1 cwt. of honey from them without reducing the number of his stocks.

To "H. W. S." and others who wish to take the bees from the honey hives and feed them into stocks, let me say in conclusion that size of the swarms should determine the size of the hives in which they are to be fed. There is a danger of using hives too large for this work. If hives are not nearly filled with combs in autumn there is the probability, I might say the certainty, of having too much drone comb built in spring, and the less drone comb we have in stock hives the better, as drones eat honey and gather none. Five pounds of bees put into a 16-inch hive, and fed with 20 lbs. of sugar made into good syrup, will nearly fill it with combs and brood. The warmer the weather is, as we have already seen, the faster the combs are built. All the syrup should be given to the bees in fourteen or sixteen days.

The easiest and best way of giving it to them is by placing a flower-pot saucer or other dish on the floor-board, with chips of wood in it, and filling it every night through a 9-inch length of half-inch gas pipe running through the hive into the dish.—A. PETTIGREW.

BEEES THIS SEASON.

WOULD Mr. Briscoe kindly give a little further explanation about his Stewarton system? I take it a Stewarton consists of three stock boxes, but that the three are seldom used the first season, as he states that he has only two used with the swarm he has hived this season, but has substituted supers for the third stock box. What I wish principally to know is, Does he drive the bees into one stock box at the end of the season and take away the other two, as of course the bees would have plenty of room in one box when the honey season is ended? Also, Is it the lowestmost box he retains and takes away the upper one? as of course the largest quantity of honey would be in them, and if there is not enough in the lower one for the winter's supply they can easily be fed up to it. I think any frame hives can be made to work on the same system as well as the Stewartons.

Referring to his honey harvest, I took last week from a stock of black bees in a standard hive 54 lbs. of honeycomb in supers, and though I had no zinc or adapting board of any kind between the stock box and the supers there were not two dozen cells in the lot tainted, and the same bees are now filling another super I put on when I took the others off—not bad for the natives. This is my second year with Ligurians, and they have not beaten the blacks yet, but I think they breed faster and swarm more; but this is not much advantage if you can only keep a certain number of stocks; however, I will continue giving both fair trials before I fall out with either.

Referring to the Stewartons, are not two stock boxes quite sufficient without three, and when the two are full add the supers?—H. J.

OUR LETTER BOX.

RENEWING A FIELD OF OLD LUCERNE (*G. R. P., a Subscriber*).—If this is a piece of land where spade culture can be available, and the old lucerne has died off and a turf of sown grass left, it would be better to cut the turf off with a spade about 1½ inch in depth, and burn into ashes during the present autumn, spread the ashes with a fair dressing of yard dung or town manure in addition, and dig-in the same deeply, and allow the land to remain during the winter and take the changes of weather; in the spring during the month of April shallow dig and make the land fine, and drill at 12 or 14 inches apart 20 lbs. per acre of seed, and apply with the seed about 4 cwt. of bone superphosphate per acre; this manure will soon drive the lucerne up out of the way of the weeds, but as soon as the lucerne can be distinguished in the rows let the ground be hand-hoed between them, and the weeds in the rows hand-pulled. If it is best adapted for horse culture let the land be rafter-ploughed, scarified across, and the old turf burnt and the ashes spread, together with a dressing of 3 cwt. of Peruvian guano per acre, and ploughed with a deep furrow, and allow the land to lay during the winter and take the frost, &c.; in the spring drag, roll, and harrow, and obtain a fine tilth, and without ploughing again drill in the month of April the same quantity of seed and manure per acre as above stated. The object of burying the ashes and manure deep in the soil is to prevent its action upon the growth of surface weeds, and to secure its action upon the deep-rooting plants of lucerne. We cannot advise the growth of a crop of potatoes, as it involves the loss of a year's growth of the lucerne; if, however, the land is very foul with couch it would be well to take a crop of potatoes, which should have a dressing of dung or guano, and after lifting the potatoes then drill with lucerne and the manure as above stated. We do not, however, recommend the drilling of lucerne the same season, unless the potatoes were an early sort and the land cleared both of crop and weeds at the earliest period. We advise wide drilling because the space between the rows should be hand-hoed or horse-hoed every autumn, and if liquid manure is not available apply 2 cwt. of nitrate of soda per acre in April every year.

REMARKS.

- 7th.—Fine day on the whole, although rather cloudy, with appearance of rain about noon.
8th.—Cloudy in the first part of morning, but afterwards fine and bright.
9th.—Fine morning, but rather hazy afternoon; brighter evening, cloudy.
10th.—Very wet in morning; fine bright afternoon; heavy rain began again in evening about 8.30, with one flash of lightning.
11th.—Fine bright morning, though occasionally cloudy; rather dull afternoon; fair evening.
12th.—Alternate heavy showers and bright sun all day; thunder at 0.35 P.M., and again between 2 and 3 P.M.; fine evening.
13th.—Heavy showers at 11 A.M. and 0.20 P.M.; fine afternoon; wet evening and heavy rain in night.

Mean barometer rather lower than last week. All thermometric mean values above those of last week, except the maximum temperature in shade and in sun, which were both about 1° below.—G. J. SIMONS.

COVENT GARDEN MARKET.—AUGUST 14.

TRADE very quiet, and quotations unaltered.

From observations taken near London during forty-three years, the average day temperature of the week is 72.2°; and its night temperature 49.2°.

METROPOLITAN ROSE SHOWS OF 1878— A RETROSPECT.

O apology is needed to write on the merits or demerits of the various Roses as seen exhibited during any season, for there are numerous readers always eager to gather any information respecting their favourite flowers. Sir Walter Scott has somewhere written that everyone could learn something even from the humblest working man. I therefore must say the same as your able correspondent said last week on fragrant Roses, that "my opinions are noted down and are given for what they are worth."

Before commencing to review the cut blooms exhibited during June and July I cannot pass by my old favourites, Roses in pots. By a little manipulation and extra attention under glass the season for Roses can be greatly prolonged, and several of our shy bloomers are to be had in great beauty when the plants are grown in pots. Roses are exhibited in pots from 6-inch pots (32's) to a No. 1, or the largest size manufactured. Plants are produced carrying from half a dozen blooms to nearly three hundred. Great skill is displayed both in the training of the huge specimens referred to and in the growing and keeping them in robust health year after year; but the smaller plants, in my opinion, give the best and largest blooms.

Roses grown in pots are generally to be had in bloom during March, April, and May; a few may be retarded to unite the indoor-grown blooms with those grown outside; but these retarded plants generally produce Roses wanting in form and beauty, unless it be those that are potted from the open ground in November, wintered behind evergreen hedges with the pots plunged, and the plants not pruned until the ordinary time of pruning the out-of-door Roses. It is from plants thus treated that the fine banks exhibited at the end of June and July are had. Some grand examples of these were shown at Richmond on the 27th of June by Messrs. Paul & Son, Cheshunt, and Messrs. Veitch & Sons from their Coombe Wood nursery. Roses in pots have also been shown well in London this season by Messrs. Veitch and Sons in the months of March and April. An extensive collection was exhibited by Messrs. Paul & Son at the Royal Botanic Society's Show at the end of April, principally grown in 11-inch pots, a size very suitable for exhibition purposes. Both flowers and foliage of these plants were simply magnificent; Madame Willermoz, La France, Marie Finger, and Cheshunt Hybrid were very conspicuous for their size, form, and beauty. The contest between those two great growers Mr. Turner, Slough, and Messrs. Paul and Son in the following month at the Royal Botanic, Crystal Palace, and South Kensington brought out the larger-grown plants: in each case Mr. Turner proved the champion. The enormous and glorious bank arranged at the latter place at the end of May displayed such a sight that has never been seen before.

The collection of Roses grown in 12-inch pots and exhibited by Mr. Turner at the Crystal Palace contained the finest flowers of any exhibited this year; the plants were

simply marvels of perfection, trained close down to the rim of the pot, more after the way that the Pelargonium is exhibited. Plants of this stamp do not take up much space to grow them nor yet to convey them to and from the exhibition. The season for Roses in pots was not one of the very best; the months of January and February were very mild, which caused the plants to break into bud earlier than usual—in fact, all through the season it was a matter of retarding Nature rather than assisting her: hence the magnificent bank referred to of Mr. Turner's, many of the plants of which were intended for Whit-week at Manchester, but were found too forward for that date.

The cut-bloom season of Roses around London commenced with the Royal Horticultural Society's Show at South Kensington on June 18th, quickly followed by the Alexandra Palace Show, the National Rose Society's Show held at the Crystal Palace, the Royal Botanic Show of July 10th; and amongst suburban Shows at Richmond on June 27th, and at Bickley on July 13th. At each and all of these Exhibitions both nurserymen and amateurs contributed largely.

As the weather has much to do with the result of achieving success in growing Roses out of doors it may be well to glance through the season of 1878. January and February were both wet and mild, and by the first and second week in March the unpruned Roses were quite green with young shoots principally broken from the uppermost buds. Now came the time for pruning, which dispensed with all previous growths, and the plants again resumed their natural state. Cold winds and frosty nights followed until the early part of April, but in due time the buds broke strongly and from then until May grew away well. The "knowing ones" predicted a very early Rose season, but the early part of June was characterised by an excessively low temperature and an entire absence of sunshine, which could not fail to retard the swelling of the flower buds and even to injure them in some localities. I recollect reading a meteorological report in a daily paper that on the day before the South Kensington Rose Show the temperature in London was 4° lower than in Iceland. Under such circumstances it was not at all surprising that the entries were not as numerous as we often see them at the early London shows; nevertheless there was a very fair quantity of Roses staged, and some remarkably fine and fresh blooms came from Salisbury, Cheshunt, Slough, Bath, and various other places. Amongst the Salisbury Roses La France was particularly fresh and beautiful, also Marquise de Castellane, Général Jacqueminot, and Marie Baumann. The collections from the late Mr. Keynes' nurseries were without doubt as fine and fresh as any they have exhibited this season; their southern position and light warm soil gave them a great advantage for this date over all other competitors. Several of the comparatively new Roses were very conspicuous in almost every nurseryman's collection, especially Monsieur Gabriel Tournier exhibited of very good form and quality. Mons. E. Y. Teas was also very prominent, and fully maintained the good opinion I formed of it last year; it is also one of the earliest to bloom, but I may here remark that that good old Rose Madame Victor Verdier is always one of the first in the field, and is both constant and free. In

the class for six distinct new Roses of 1876 and 1877 Madame Deverel, Mons. Gabriel Tournier, Mrs. Laxton, Oxonian, Mrs. Baker, and Sultan of Zanzibar formed Mr. Paul's selection, and I say without fear of contradiction that the two varieties raised at Cheshunt were the cream of the collection, for Mrs. Laxton and Sultan of Zanzibar as exhibited were splendid both with regard to shape and colour. I shall be very much surprised if Mrs. Laxton does not make one of our most constant exhibiting varieties. Oxonian, another new English-raised Rose, flowered very early, and its shell-like petals, combined with its great substance, will render it a great favourite. It is also a Rose that is not easily injured by heavy rains. Messrs. Paul & Son staged at this show a richly coloured claret-red bloom of Dr. Hogg, very distinct. All agree that there was a very creditable display at the Alexandra Palace, but unfortunately I was prevented from being present. I am also told that Mons. Gabriel Tournier as shown there was very coarse.

From the 18th to the 25th is exactly seven days, which made a great difference in the mean temperature, and tropical heat had fairly set in. The maximum heat registered in many places on the latter date exceeded 90° in the shade, and the nights were correspondingly hot. Roses that were mere buds in the morning were full-blown at night, and those cut early in the morning for exhibition displayed coarse eyes before there was scarcely time to set them up in their proper positions. Very severely was this felt under canvas tents, and at Richmond the glorious blooms sent by Messrs. Paul & Son and several others from a distance that were obliged to be cut overnight were all overblown before the day was half spent. The only flowers that had anything like a respectable appearance towards afternoon were those which came from Messrs. Veitch & Sons and Messrs. Lee from their Ealing nursery, which were cut very late on the morning of the show. Messrs. Lee exhibited at Richmond a collection of twenty-four La France that were models of perfection, and stood all day unscathed. From these observations I in common with many others would like to solve the problem, When is the best time to cut? My experience is that blooms cut overnight invariably stand better than those cut very early on the morning of the show, especially if they are covered with a very heavy dew; but blooms cut, like the Ealing and Coombe Wood collections after the sun has risen some few hours, will stand a better chance against those cut overnight in times of such exceptional heat. Let anyone stroll along a collection of Roses, say from two to three o'clock in the morning, and he will find numbers of fully open flowers that are simply grand; but if those blooms are cut then and exhibited, and if the day proves hot, nothing but disappointment can follow. Let the same observer also notice an opening bud, and in a very short time if he returns again he will find a fully expanded flower: so that the solution arising to my mind is either to cut while the blooms are warm and dry on the previous evening or after the morning dews have left them. It would be well if other growers stated their experience in this matter.

To continue my notes. That grand tournament, the National Rose Society's Show, was held when great heat prevailed, but canvas was admirably arranged to come very low down towards the boxes; the floors had been well saturated with water, and the whole Show was refreshingly cool. It could not, however, be inspected comfortably, for the space allotted to the public was far too narrow. To particularise any one flower from such a quantity exhibited will appear almost invidious, but mention should be made of *Souvenir d'Elise*, for it was almost, if not quite, the grandest Rose in the whole Exhibition. A box of *Capitaine Christy* from Mr. G. Paul was indeed splendid. *Mdlle. Marie Rady* was also magnificent, and as for *Horace Vernet* and *Marie Baumann* they were beautiful in the extreme. *Le Havre* also played a most prominent part, as did several other of our well-known old exhibition varieties. Before passing from the Palace Show it may be well to remark that that good and much-admired Rose *Etienne Levet* was nowhere, and in almost every case where it was included in the collections it presented a bleached appearance. *François Michelin* has not been up to its usual standard of excellence this year.

On the 10th of July, when the Royal Botanic Society held their Rose Show, the weather had become much cooler, and some heavy rains had fallen in the interval, so that maiden blooms were shown there magnificently by several nurserymen, notable amongst them were Messrs. Paul & Son and Cranston and Co., and I have never seen better blooms exhibited anywhere than by these two firms, who staged enormous flowers of *Reynolds Hole*, *La Duchesse de Morny*, *Louis Van Houtte*,

Madame Lacharme, *Le Havre*, *Alfred Colomb*, &c. A grand bloom of *Jean Sury* was also exhibited both in Mr. Paul's collection here and on the following Saturday at Bickley. It is a Rose sent out about the same year as *Horace Vernet*, and as shown by Mr. Paul a deep and well-built flower of excellent shape. Messrs. Paul & Son also exhibited at this Show a basket of *Alfred Colomb* containing exactly one hundred blooms which were remarkably fresh and fine. This gorgeous display rivetted the attention of everyone, and when H.R.H. the Duchess of Teck saw them she was so enamoured by their beauty that Mr. Paul sent them to her as a present after the Exhibition was closed.

At Bickley on July 13th I noted *Jean Soupert*, *Pauline Talabot*, and *General Von Moltke* as very promising Roses in Messrs. Veitch & Sons' collection; this last is a splendid dark Rose, and is spoken very highly of by Mr. Hills, Messrs. Veitch's Rose-grower. Messrs. Paul & Son had *La Duchesse de Morny*, *Marie Rady*, *Jean Sury*, *Mdlle. Marie Finger*, and *Louis Van Houtte* in admirable condition.

Madame Sophie Tropic and *Louis Pernet* are two good additions. They have been exhibited in good form in almost every nurseryman's collection throughout the season. *Duchesse de Vallombrosa* has also met with the favouritism she deserves as a light Rose, and amongst newer additions *Penelope Mayo*, *Countess of Rosebery*, *Duchess of Bedford*, and *Earl of Beaconsfield*, all English-raised Roses, have exhibited some very promising qualities. The very best white Rose yet sent out, not a Tea, is without doubt *Madame Lacharme*, which has frequently been exhibited of both extraordinary size and purity this season. To attempt to say which is the best dark Rose I cannot, for the Cheshunt firm is growing rich in them, but *Reynolds Hole* and *Louis Van Houtte* will not be very far behind in competition. *Star of Waltham* will hold its own for many years to come; its form and substance can scarcely be excelled. *Royal Standard* has also been fine, the warm weather evidently suiting it, but I fear its beautifully delicate soft satiny rose-coloured petals will get sealed during wet summers. *Jean Soupert*, *Jean Liabaud*, *Abel Carrière*, and *Madame Prosper Langier* may be considered desirable acquisitions where a collection is aimed at.

The tropical weather did not last long, but sufficiently to cause the cutbacks to be in bloom almost all at one time; the wood became ripened and fresh growths burst almost simultaneously, which are now giving a very fair supply of second blooms.—J. W. MOORMAN.

AUTUMN PRUNING OF FRUIT TREES.

OWING to the general absence of fruit, and to the rains that have periodically fallen throughout the season, the growth of fruit trees is unusually exuberant. The importance of summer pruning has been pointed out and much has been done; but, on the other hand, many more trees have as yet received little or no attention in the matter of thinning out superfluous growth and exposing the foliage at the base of the shoots to the action of sun and air.

The importance of admitting the sun to the foliage of fruit trees, not at the tips of the shoots but at the base, cannot be too strongly urged. It is only by inducing the formation of perfect and fully developed foliage at the base of the shoots that fruiting spurs can be formed. Large leaves form freely enough in the crowded and shaded portion of a tree; they are indeed often larger than the leaves that are fully exposed, just as the growths in the interior of a tree are more exuberant than those on the outside; but such growth is useless, and its very exuberance is caused by an effort to gain light and air. The grossness is a result of shoot struggling with shoot, and leaf with leaf, in an attempt to emerge from the semi-darkness of the tree's interior, in order that they may obtain what are so essential—namely, light and air, to enable the foliage to perform its natural functions of assimilating food and storing it for the tree's well-being, and to render it really healthy and fruitful. If a tree is let alone it will eventually bear fruit on the extremities of the branches. In the battle for existence some shoots will assert their supremacy and the weaker will succumb. Thus it is that so many trees become destitute of bearing wood at their base and in the interior of the heads.

It is the duty of man to intervene in this battle of nature by admitting the light to the foliage by the timely and judicious thinning-out of the branches. Hundreds of fruit trees are at the present moment crying out with Goethe for "light, more light." Give them that light, and in due time they will give a

return by (weather permitting) regular crops of fruit over the whole extent of their branches.

All trees that are crowded should be attended to now by having a great portion of the shoot removed almost entirely rather than by shortening systematically the whole of the growths. At no other period of the year can the operator so well see what growths should be removed as at the present time. Let them be removed promptly, be they large or small, and much greater benefit will be done to the trees than can be effected by any amount of winter pruning, however skilfully the work may then be done. The wounds made by the knife now heal much more quickly than do wounds made in winter; and if branches are severed when the trees are in a growing state the foliage remaining takes care that there is no waste of sap, which is simply diverted into other channels and turned to good account by the leaves then under the action of light.

If the month of September proves bright fruit trees may yet, with such aid as can be afforded them by thinning and pruning, mature their wood and perfect fruit blossoms for another year; but if the trees are neglected now and are permitted to struggle for the light they are seeking, we have no right to expect that they will in any reasonable time arrive at a fruit-bearing state.—AMATEUR CULTIVATOR, *Owon*.

SHOW PELARGONIUMS.—No. 2.

APART from the admitted beauty of Show Pelargoniums they are interesting as showing in a remarkable manner the improvements that may be effected by judicious hybridisation. During late years varieties of the Zonal type have increased as if by magic, and the improved forms and new colours that have been produced have excited the wonder of ordinary cultivators. So rapidly has one variety of this section succeeded another that the advances made in Show Pelargoniums have been comparatively overlooked. The improvements, however, in this fine section are none the less decided on that account. Indeed the difference between the original parents (if they can be traced) of Show Pelargoniums—such, for instance, as the loose white-petalled straggling grower *P. grandiflorum*, and the lilac-purple species *P. cucullatum*, and the splendid varieties now in cultivation—is even greater than the dissimilarity between the modern Zonals and their progenitors *P. zonale* and *P. inquinans*. No flowers in cultivation have given a richer reward to hybridisers and cultivators than Show Pelargoniums, and no flowers even now give a better return for care and skill bestowed upon them than these beautiful and indispensable greenhouse plants.

Whenever a supply of flowers of high quality is desired in the late spring and early summer months, say from March to July, then Show Pelargoniums must be grown. The Zonal varieties are simply invaluable during the same periods, indeed at nearly all seasons; but we have no right to make that an excuse for not growing the Show varieties. It were as reasonable, even more so, to refuse to grow Turnip Radishes on the plea that the long-rooted sort is better, as to contrast the claims of the two sections of Pelargoniums alluded to. They are in fact, to coin a word, uncontrastable, and are both for exhibition and home decorative purposes as distinct as if they belonged to two genera.

If Show Pelargoniums have been “under a cloud” for a time we have the more reason to feel obligated to the nurseryman-florist, Mr. C. Turner of Slough, for continuing as he has done the cultivation and improvement of these plants. Never once does he appear to have flagged in his efforts in obtaining and introducing new varieties. He had faith in the flower, and a flower possessing such sterling merits as this was not likely to deceive him. Once again it is rising into popularity, as is evident by the increasing demand for plants made on those who sell them, and the still more frequent requests for cuttings made to those who are supposed to give them away. I have ceased giving away cuttings indiscriminately, having found by experience that plants that cost nothing are often not valued at half their worth. If flowers are really loved they will be purchased by those who have the means of purchasing them, unless, indeed, money is loved for its own sake more than the flowers are for their beauty and for the pleasure they are in many ways capable of imparting. But many lovers of flowers hesitate purchasing because they do not know what to purchase. They are not practically acquainted with the varieties, and hesitate ordering plants lest they should be disappointed with them when the flowering period arrives.

It is not usual that those who are commencing the cultivation

of any particular class of plants purchase in the first instance the newest, and necessarily the most expensive, varieties. Those who order the novelties generally have a special knowledge of the plants they cultivate, and require new sorts to add to their already good collections. I will not on that, and also on another account, enumerate the latest introductions; the “other account” being that I have only seen some of them and have not proved them. Those that I recommend are worthy of general cultivation I have proved.

The difficulty is, out of varieties so numerous and yet so good, to make a limited selection. The following, however, are all good, embrace a wide range of colour, and are not expensive; they are, indeed, as well worth the money they cost as any other varieties of any other plants with which I am acquainted—Ruth, prevailing colour very deep rose with a maroon spot on the upper petals and a pure white centre; it is of fine form, smooth and glossy, and is without doubt one of the most beautiful varieties in cultivation. Prince Leopold, very bright, approaching scarlet, smooth and free. Purple Gem, the finest of its colour and very distinct. Claribel, a fine contrast to the above; old, but still one of the best whites. Example, rosy crimson with dark blotch; constant and free. Ambassador, rich pink; white eye. Potentate, top petals maroon, lower petals rose; white centre. Scottish Chieftain, top petals dark maroon, lower petals crimson; rich and free. Troubadour, orange pink, maroon spot, white centre; smooth and good. Charles Turner, orange scarlet; a brilliant flower of fine form. Forester, deep rosy pink, maroon spot, white eye; distinct. Gipsy, very dark and rich; white eye. Achievement, rosy lilac and maroon, white centre; distinct and good. Diplomatist, rosy purple and maroon, white eye; fine. Challenger, deep scarlet and maroon; very rich. Archduke, maroon and pink; white centre. Brigand, cherry pink, with maroon spot and white centre. Chieftain, rose, maroon spot; lower petals shaded with lilac, white centre. Constance, fawn shaded with orange; a fine variety. Vesuvius, bright scarlet and maroon; free and good. Mountaineer, a fine bold flower; crimson and maroon, light centre. Kathleen, salmon pink, maroon spot; smooth and fine. Crown Prince, crimson and maroon, clear white centre; fine. Charlemagne, salmon peach and maroon spot; large flower of good form.

The above-named twenty-four varieties are all good. If only six sorts are wanted take the first six, and if twelve choose the first twelve; and if the plants are well grown they can scarcely fail to give satisfaction.—A NORTHERN GARDENER.

ONIONS.

OUR Onion crop has proved very good this year. We sow the seeds and treat the crop as has already been described in the Journal; and perhaps it would not have been worth while calling attention to the subject again, only I wish to give my opinion of two Onions we have grown this season for the first time. The first is new Queen. I cannot quite make out the relation between our sort and the description of it given in some nurserymen's catalogues, as it is described as being a small Onion. At the time James's Keeping, Bedfordshire Champion, Danvers' Yellow, and others had not formed a bulb at all, our new Queen had roots 6 and 7 inches in circumference, and they are now 15 inches round. So much for its size; but its earliness is its greatest recommendation, and if it is grown on this account it will be found very useful. The next one is the Improved Banbury. This has also taken the lead of all the others in size, and it is of first-class form and as hard as a stone. We have them measuring 13 inches round, while none of the others will exceed 12 inches. Of course these measurements only refer to spring-sown produce, raised without any “feeding” or assistance but the ordinary soil they grow in.

The Queen Onion, I should think, would be very suitable for autumn sowing, and would in all probability form bulbs in spring sooner than any other variety.—A KITCHEN GARDENER.

WALTHAM CROSS VINE.

I PLANTED a cane of it on the 3rd of May, 1877. It grew very vigorously last season, and the rod this year is 18 feet long and stout in proportion. After being cut back it produced several bunches, three of which I have left on. These are now just ripening. The berries are very large and handsome; the flesh is firm, but it is not yet sufficiently ripe to judge of the flavour. I find it a free setter—quite as free as

Black Alicante growing in the same house, and should it finish off as it promises to do I shall consider it a first-class Grape.—
J. PRINGLE, *The Gardens, Ponsbourne Park, near Hertford.*

PELARGONIUM SOCIETY.

THIS thriving Society held its fourth annual meeting on August 14th at Chiswick, when the following report of the Executive Committee was adopted:—

"The Executive Committee, in laying before the members the Society's fourth annual report, have the satisfaction of being able to refer favourably to the labours of the past year and to the Society's present position. They congratulate the members on the increased popularity of the Society, as evidenced by the accession of new members and by the great liberality of its old and well-tried supporters—this popularity, as they believe, being mainly attributable to the endeavours constantly made by the executive to stimulate the production of improved varieties in all sections of the family, thus making its admirers still more convinced of its usefulness, and at the same time educating and improving the popular taste.

"The Exhibition held at South Kensington on June 18th was a decided success, since the specimen plants were well grown and flowered, and presented a fine display, and the progress made in all sections of the Pelargonium family was satisfactorily represented in the exhibits of new varieties. It is still to be regretted that many members withheld from exhibiting, and this fact will induce the Executive Committee to propose, for the approval of the members, such modifications of the prize schedule for 1879 as they hope may tend to remedy this defect.

"The Executive Committee take this opportunity to tender their thanks to Mr. Kinghorn, Mr. G. Smith, and Mr. Moore, who fulfilled the onerous duties of Judges. They desire also to call attention to the fact that some of the prizes were withheld by the Judges on account of the inferior character of the exhibits, and wish to impress upon the members that this course is necessary to the full realisation of the objects for which the Society was established—namely, the attainment of the highest standard of perfection in the exhibits of new varieties and the best state of cultivation in the older varieties. Any other course would be detrimental to the Society, which would in that case utterly fail to carry out its avowed objects.

"The Society have again to acknowledge the substantial and valuable assistance rendered to it by the Council and officers of the Royal Horticultural Society—first, by the cultivation of their collections at Chiswick; and, secondly, by the facilities afforded for holding their exhibitions. The Society's warmest thanks are also due to those exhibitors of other subjects who came forward so liberally, and by their magnificent ornamental groups added so much to the effect and beauty of the show.

"The Executive Committee hope to be able in the ensuing year to carry out their desire of publishing a list of all the new varieties in all the sections of the Pelargonium family, and of notifying those varieties which they consider superseded, and which consequently would be better withdrawn from cultivation.

"The annexed balance sheet presents a satisfactory view of the Society's financial position so far as it goes. Increased exertions are, however, needed on the part of its members, so that the number of prizes offered in some of the classes may be increased, as well as to provide means to acknowledge in some slight degree valuable aid now gratuitously rendered, and to maintain the Society in an independent position."

Examined and found correct, (CHARLES NOBLER,
July 2nd, 1878. (EDMUND B. FOSTER.

The officers for the year ensuing were appointed as follows:—
Chairman, James McIntosh, Esq., Duncreevan, Oatlands Park;
Vice-Chairman, E. B. Foster, Esq., Clewer Manor, Windsor;
Hon. Treasurer, Dr. Denny; Hon. Secretary, Mr. T. Moore, F.L.S.
Committee—Messrs. Browne, Cannell, Catlin, Fraser, George, Henderson, Hibberd, Hogg, James, Kellock, Kinghorn, Laing, Llewellyn, Masters, Peach, Pearson, Postans, Sisley, G. Smith (Hornsey), G. Smith (Edmonton), Turner, H. J. Veitch, Webb, West, and Wilson. The schedule of prizes for next year under-

went discussion and amendment, and it was unanimously agreed that the Society should award certificates of merit to deserving novelties exhibited at its shows.

INTERMEDIATE STOCKS.

As a rule the sweet and attractive spring-flowering plants are not grown in private gardens to the extent that their merits deserve. From March to June they form a delightful feature in the decoration of greenhouse, conservatory, window-sill, and garden.

Nowhere are these Stocks seen finer than in Covent Garden Market, where they are sold by thousands for the decoration of metropolitan homes. The growers of the plants have special facilities for cultivating them, and have probably special strains of their own; at any rate the market plants are remarkable for their dwarf sturdy habit, rich colour, and early-flowering qualities. Be this as it may, it is certain that the principal seedsmen can supply Intermediate Stock seed that will produce plants of good habit and which will yield a large percentage of double, sweet, rich flowers. The scarlet, or rather crimson, variety is the best; if whites and other coloured dwarf Stocks are desired early in spring they can be had by sowing seeds of the Ten-week Stocks in September. Lothian Stocks are probably the finest of all for winter and spring flowering, but they require a much longer period of growth than the varieties above named, and it is too late to sow the Lothians now for producing early spring-flowering plants; it is, however, just the time for sowing seed of the Intermediate varieties.

Let it be sown at once if possible, and not next week or the week after, or the plants will not become large enough before winter to produce stout spikes early in the spring. Sow very thinly in rich light soil in the open garden. If the soil of the garden is naturally heavy prepare a compost of light loam and very much decayed manure or leaf soil in equal parts, and make a bed of this about 3 inches thick in which to sow the seed. If the seed bed can be so formed as to be covered with handlights or other glass protectors so much the better, as if drenching rains occur when the seedlings are in a small state much injury may be done; still the young plants must not be coddled, but should be encouraged to assume a sturdy habit of growth from the very beginning of their career.

When they are large enough to be handled, and before they are in the slightest degree crowded in the seed beds, pot them singly in 60-sized pots, place them in a frame and keep them close for a week, and shaded if the weather is sunny, but the moment they can endure the sun they must have it, also all the air possible, even to the extent of removing the lights entirely night and day during settled weather, and dwarf vigorous plants will be produced before winter. They must be wintered close to the glass in very light frames, and must have protection in severe weather. They will require little water during the dull days, yet must have sufficient to keep them in a fresh growing state, but decay of the foliage must be specially guarded against.

If very dwarf plants are required let them remain in the small pots until they produce flower buds, and the moment it can be ascertained which will be double and which single shift the former into their blooming pots, using very rich turfy soil, and in a few weeks attractive plants will be produced which cannot fail to be generally admired.

It is customary in private gardens to place three plants in a 48-sized pot, and there leave them to flower; but this is not often satisfactory, as one of the plants may prove single, and it may happen two, and a plant never looks well growing close to the side of a pot. It is far better to pot them singly, as the plants, if well grown, assume a natural dwarf pyramidal habit, which can never be so well displayed as when the plant is placed in the centre of its pot. But although double flowers are naturally the most admired, yet the singles are by no means to be despised in early spring. Pot three or five of the single plants in 7 or 8-inch pots, and large floriferous bushes will be produced, which will be found very valuable for affording cut flowers for vase decoration and bouquets, the singles being as good or even better for those purposes than the doubles.—
A CONSERVATORY FOREMAN.

THE POTATO CROP IN SOUTH WALES.

As the Potato crop is always an important one, perhaps it may be interesting to state that about here the crop is excel-

lent this year. Last year the disease was fearfully bad, about 80 per cent. of the tubers in both gardens and farms being destroyed; but this year it is the very reverse, not 20 per cent. being diseased, and the tubers are both larger in size and more numerous than they were last season. We have not a rain gauge here, but I should imagine that six times as much rain fell during the latter part of May and throughout June, July, and the early part of August last year, as has fallen during that time this season, and I think it is to the dryness of the weather that we have experienced during the last three months that the goodness of the Potato crop may be attributed.

A variety named Early Mealy and Prince of Wales are two that are the most subject to disease amongst all the varieties we grow. Paterson's Albert, Paterson's Blues, and in fact all of Paterson's varieties, are excellent Potatoes both for abundance of crop, resisting the disease, and quality. Although many of the American sorts have the reputation of possessing all these qualities I do not consider any of them equal to Paterson's. The American Snowflake, however, is a very handsome Potato, and for exhibition it has few equals. Sutton's new Magnum Bonum is a Potato which I think will soon be much grown. Here Gloucestershire Kidney is the best of its class, and I would advise any of your readers who do not possess it to try a few of it next year.—J. MUIR, *Margam*.

STRIKING ROSE CUTTINGS—DISBUDDING.

No time of the year is more suitable for the insertion of Rose cuttings than the present, and there are very few Roses that will not thrive as well on their own roots as when budded on the Briar or Manetti. In some soils, and probably the majority, a better growth and finer blooms are produced by Roses grown from cuttings than by any other mode of increase. I am not now writing of Roses for exhibition, but Roses for making the garden gay and sweet, and rooms gay and sweet too, for I like to see Roses grown so that they can be cut by the bushel and yet not be missed from the bushes.

Like many more, I have never been able to buy Roses by the hundred, but I am thankful to say I have had the privilege of growing them by the thousand. A dozen or two at most are all that have been purchased annually, and then the object has been to increase those that were esteemed good, so as to have them in abundance. To this end Briars have been obtained and Manetti cuttings struck and eventually budded, and the same practice continues, but the most satisfactory mode of increase is by striking cuttings of the Roses themselves. It is not the quickest mode, but it is the safest, and in the end affords the best supply of blooms and buds.

Blooms and buds! I cannot refrain from repeating the words in the hope that something will be done to encourage Roses being exhibited in a less starchy, formal, and artificial manner than is the fashion at the Rose shows. Let the buds—the fresh, sweet, beautiful, half-expanded buds—have a better place than the rubbish heap, to which so many basketfuls are consigned in obedience to the law of exhibiting. Those buds are considered as robbers, but I consider those who pluck them so mercilessly greater robbers still. “D., Deal,” has written strongly against dressing Carnations and in favour of the flowers being staged in a natural manner, and I hope he will on the same principle do something to encourage the natural beauty of the Rose being preserved and exhibited at the shows.

But to return to the cuttings. Let them be taken off and inserted at once. That is the principal point in connection with the work. If they are severed from the trees, and permitted to flag and become partially shrivelled before insertion, they will not emit roots so quickly as if they are kept fresh and moist. The cuttings cannot be inserted too quickly after they are made. If the wound is permitted to dry up in the air it is slow to form a callus in the earth. That is a point worth remembering when Rose cuttings are inserted in summer.

Select shoots that are tolerably firm. Soft succulent growth is of no use; on the other hand, hard stunted wood seldom strikes freely and grows vigorously. The lower portions of the shoots produced this year make excellent cuttings—such shoots that are cut off for having their buds extracted. Make the cuttings the same as Geranium cuttings—that is, cut them across close under a joint and remove the leaves for a length of 4 or 5 inches. Leave one pair of leaves at the top and insert the cuttings firmly up to the leaves, leaving two eyes only above ground. The soil should be light and moist, and the position shaded. If the weather is not showery they must be sprinkled frequently so as to preserve the foliage fresh, and roots will form

so much the quicker. They should be inserted in rows a foot apart, the cuttings being 3 or 4 inches asunder in the rows, and there they should remain for about eighteen months. Only a small per-centage will fail to strike. Most varieties strike fully as well as cuttings of the Manetti; in fact, the cuttings will form plants quicker than can be produced by budding on Manettis, counting from the time (which is quite fair) when the Manetti cuttings were inserted.

I have struck hundreds—I may say thousands—of Rose cuttings in August, and it is rare indeed that blooms cannot be cut from April to September, commencing with the old Monthly China Rose growing against the south wall of the garden, and finishing with that and such sorts as Gloire de Dijon and Souvenir de la Malmaison on the north border.

I had almost made up my mind not to write about Roses again since the Editors were troubled with forwarding so many letters to me, but I have ventured to write on a point of practice which is not likely to give rise to after correspondence.—A PARSON'S GARDENER.

FRUIT CULTURE IN KENT.

ON the invitation of Mr. L. Killick of Mount Pleasant, Langley, Maidstone, the proprietor of extensive orchards and Hop grounds, some members of the Fruit Committee of the Royal Horticultural Society visited Maidstone on Friday last, and inspected some of the fruit-growing establishments in the vicinity of that town. After partaking of a preliminary luncheon at the Star Hotel two waggons conveyed the visitors to Barham Court. The route selected was a most picturesque one, the road passing through the village of Tovil, and overlooked almost along its whole course the beautiful valley of the Medway and the gently undulated rising ground beyond. Orchards old and new of Cherries, Plums, and Apples, some having an undergrowth of grass, others of Currants, &c., formed next to the Hop grounds the principal feature of the landscape, and as a change from the Hops and the fruit trees was here and there a Raspberry field. Hops were on all sides and everywhere, the crops varying extremely according to the state of the soil and the absence of insects and mildew. Many of the stools and poles were almost destitute of inflorescence; others were producing only large clusters at the top; and a few, but only comparatively a few, were well furnished almost to the ground, and bearing really good crops; and unfortunately some that were producing the finest hops in the greatest profusion appeared to be the most seriously affected with mildew. Yet although a full average crop is not expected, the appearance of the grounds, while the foliage is yet green and the hops are just approaching maturity, is imposing to such visitors who are not accustomed to the Kentish mode of ground cultivation. Tostin bridge was reached and crossed after a drive of about three miles; and another mile traversed, the first halting place was reached at Barham Court, and Mr. Roger Leigh's unique garden was inspected.

The fine trees on the lawn were greatly admired, especially a magnificent example of the Cedar of Lebanon with more than a dozen leaders, each of them of tree size, the head being about 250 feet in circumference. Two trees of Magnolia grandiflora on the open lawn attracted notice, as also did a handsome pair of the Willow-leaved Oak. Passing rapidly through the plant houses near the mansion and noting the health and cleanliness of the specimens, especially luxuriant and highly coloured plants of Adiantum farleyense, and onwards round the mansion and through a small flower garden—a charming dell-like enclosure, containing an admirable example of Pulham's rockwork, also subtropical plants and carpet beds—the fruit gardens were reached. These, as has been previously mentioned in the Journal, are arranged on the French system. An extensive collection of fruit trees is admirably managed by Mr. Haycock, but this year, as a rule, the trees are not producing anything like freely; yet to the rule there are some pleasant exceptions. Notably is this the case with the following Pears grown as diagonal cordons on a wall having a west aspect—namely, Winter Nelis, Joséphine de Malines, Beurré Hardy, Beurré d'Anjou, General Todtleben, Beurré Bachelier, Doyenné du Comice, Durodeau, and Louise Bonne of Jersey. The above are bearing excellent crops of fine and highly coloured fruit, but several trees on the same wall of Easter Beurré are in very indifferent health, their condition being attributable to the French stocks on which the trees are worked. Peaches on the south wall are also bearing full crops, and a row of diagonal cordon-trained Calville Blanche Apples at the foot of

the wall is also bearing a good sprinkling of fruit. Apples are grown in great numbers and in various forms, as diagonal, vertical, and horizontal cordons on wires; also as bushes and pyramids. A few trees of the pretty Lady Apple are wreathed with small scarlet fruit; and also bearing well are Reinette d'Espagne, Fall Pippin, Royale Anglettere, Forge Apple, Golden Spire, New Hawthornden, Emperor Alexander, Kerry Pippin, and some others, one of which named Maltster attracted much notice. It is a large, smooth, solid Apple of much promise, and the tree is a healthy grower and forms fruit spurs freely. The trees constituting this fine collection were mostly obtained from France, and some trouble has been given by the incorrect nomenclature of several of them. Mr. Haycock's intimate knowledge of hardy fruits enables him to correct mistakes as the trees come into bearing, and shortly the entire collection will be correctly named. This, however, is work that ought to be done in nurseries, and, in fact, is done in all English establishments of repute, where the trees would be unhesitatingly burnt if any doubt existed as to their right names. Many trees are also grown and fruited in pots at Barham, some in a large orchard house, and others plunged in beds enclosed by low brick walls, the blossoms being protected by canvas. Most of these trees are producing good crops, especially the Plums.

Besides inspecting the fruits outside several ranges of glass were passed through. From the Peach houses all the fruit had been gathered, but good crops of Grapes, especially Madresfield Court and Muscat of Alexandria, were hanging on the Vines. In some pits excellent crops of Cucumbers and Melons were hanging, the latter being especially fine, the varieties being Eastnor Castle Green Flesh, Cox's Golden Gem, and Golden Queen. These pits are three-quarter spans, and the path through them is close to the back wall under the short lights facing the north; over this path from end to end, and also through the Pine pit, Vines in pots are trained in the form of an arch, which forms a shady arcade of foliage, attractive in appearance and conducive to the ripening of the canes. These Vines are very fine, and are certain to produce heavy crops next year.

Leaving Mr. Leigh's garden the next halting place was at Mr. Leney's, The Orpines, Wateringbury. This place, though not a garden, was too celebrated to be passed, on account of its world-famed shorthorns—the renowned Wateringbury herd. An animal was shown which £5000 would not buy, and amongst many others of great value a cow (The Duchess), whose last two calves realised upwards of £5500 when they were six months old. Such animals were worth seeing, and they can be appropriately mentioned in this Journal, where agriculture is allied with its twin sister horticulture. The visit to Orpines will be remembered by the visitors, not only for the shelter they obtained from a drenching and somewhat protracted shower, but also on account of the hearty welcome and hospitable reception accorded to them by Mr. Leney.

A long drive being yet in the programme and time flying a short cut of five or six miles was determined on to Boughton Monchelsea. The route was through the village of East Farleigh, where the Crittenden Damson originated, that is so highly and deservedly esteemed by the Kentish fruit-growers. It can be said with truth of this Damson that no other variety of fruit tree in the Kentish orchards is this year bearing so constantly, regularly, and freely as this Damson. Wherever trees are seen they are crowded with purple fruit, and all the trees are on their own roots—i.e., they are raised from suckers, or, to use the local term, "spawn," and are not grafted or budded on other stocks. Shortly after leaving Farleigh, Linton Park with its neat entrance lodge was passed on the right, and on the left the home of one who is held in high esteem by all who know him, and who is respected by thousands of others to whom his name is familiar—John Robson. Mr. Robson's home consists of a commodious house, termed Stone House, and, what must make it emphatically a "home" to him, a very large garden. Long borders of bright flowers skirt the path to the house, and behind the flowers are hundreds of fruit bushes and trees. It was welcome to hear his name so pleasantly mentioned and his works as a gardener and a writer so highly appreciated. Mr. Robson's is a pleasant home, and congenial; long may the veteran live to enjoy it. Rain threatening, luncheon waiting, and the guests behind time, the horses were perforce urged swiftly on to Jack Stonham's, at least that was the name boldly inscribed on the sign of the roadside inn at Boughton Monchelsea. On Mr. Jack Stonham's house the good old Gloire de Dijon Rose luxuriates. In a building contiguous to

the inn a luncheon was provided at the instance of Mr. Killick—a spread that places Mr. Stonham in an honourable position on the list of caterers. It was bountiful to a fault, and in all respects excellent. Mr. Killick presided at the luncheon, and Mr. Skinner, another extensive Kentish fruit-grower, occupied the vice chair. After the repast Mr. Killick proposed the toast of the Royal Horticultural Society, and expressed the pleasure it gave him to see its representatives present. He coupled the toast with the name of Mr. Henry Webb, a Vice-President of the Society and Chairman of the Fruit Committee. The volleys of "Kentish fire" having subsided Mr. Webb replied, expressing the pleasure that he and his colleagues had experienced by the visit. He referred to the useful work, so far as related to practical horticulture, that the Society had done and continued doing, especially at the periodical meetings of the Society and the experiments conducted at Chiswick. He looked hopefully towards the future, and offered a welcome to all fruit-growers, horticulturists, and gardeners who were disposed to enter the ranks of the old and honourable Society. Mr. William Paul in felicitous terms proposed the health of Mr. Killick, who, after more "Kentish fire," briefly replied by expressing a hope that this was only the first of a series of annual visits that he would be honoured with by his friends.

A flying visit was next made to a portion of the fruit grounds of Mr. Skinner, not a tithe, however, of which were seen, for night was creeping on. The grounds can only be fittingly described as a forest of fruit trees with an undergrowth of Kentish Cob Nuts and Filberts. The trees appear to be left very much to Nature, and a few of them are of great size, especially some Golden Knob Apples carrying good crops. Very many trees are barren, but not so the Loddington Seedling or Stone's Apple. This variety is naturally a medium grower, but every tree had a good sprinkling of fine fruit. King of the Pippins was bearing heavily, as also was Yellow Ingestrie, while Lord Suffield, Blenheim Pippin, and Cox's Orange Pippin were producing moderate crops; but the Nuts, perhaps, attracted more attention than the Apples. If the bushes are not centenarians they are not far from being so, for their trunks not more than 2 feet high are as thick as a man's body. From these stems from six to twelve branches have been trained almost horizontally. These main branches are now old, gnarled, and moss-covered, yet from them issues luxuriant growth, and in good seasons abundance of fine Cobs. Many of the bushes are upwards of 15 feet in diameter, and are about 5 feet high. They are quite open in the centres—are trained in fact, in the shape of saucers. They had just undergone their summer pruning by having had all the luxuriant young wood broken off a little distance from the base of the shoots and scattered on the ground. There appear to be acres, perhaps miles, of such bushes as those described, but this year the crop of nuts is a scant one.

From Mr. Skinner's grounds to Mr. Killick's is only a short drive, and Mount Pleasant, Langley, was reached just as the shades of evening were approaching, and some of the visitors had to rush off in hot haste to secure the train before half of the place had been seen. Hop grounds fringed with Crittenden Damsons, orchards old and young on grass, and a large young plantation of Apples carefully tended in well-cultivated ground were rapidly passed through. The most striking of all the fruits was the Damson above noticed. Trees, hundreds of them, only five years old, have heads as many feet in diameter and are masses of purple fruit. Of Plums few appear to be bearing well except Victoria and a variety designated the Bush Plum. Of Pears the Hesse is about the only sort carrying a good crop. Many Apple trees are barren, a few fruitful. Among the latter Loddington Seedling was conspicuous. Others which attracted notice were the Hanwell Souring, a free grower and good bearer; Tower of Glamis, a variety of great promise; Ecklinville, free and fine; Golden Spire, a free-bearing, early, cone-shaped Apple somewhat resembling Lord Suffield; Maltster, very fine; Emperor Napoleon, a deep, rich red Apple of fine appearance; and Early Julian, one of the best of the early sorts. This young plantation of Apples will be highly worthy of inspection in future years. Old trees cannot be referred to except to notice an instance of grafting which is common in Kent. Instead of the trees being headed-down to the trunk and half a dozen grafts being inserted the branches are cut off at 5 or 6 feet from their base, where the wood is comparatively young and the bark smooth. They are then grafted, fifty or more grafts being inserted on one tree. Large heads are speedily formed and the head is soon in a bearing state, the tree instanced, Loddington Seedling, grafted on an

old stock having produced five bushels of fruit the third year after the grafts were inserted.

Mount Pleasant is indeed a pleasant place, pleasant by the splendid scenery in the distance and by the fruit and flowers immediately surrounding the house. It was made pleasant also, very pleasant, to the visitors by the genial welcome they received and the manner in which their wants were anticipated and gracefully supplied by Mrs. Killick.

Amongst those who accepted Mr. Killick's invitation were Mr. Henry Webb, Mr. John Lee, Hammersmith; Mr. Lane, Great Berkhamstead; Mr. William Paul, Waltham Cross; Mr. Dancer, Chiswick; Mr. Harrison Weir, Mr. Haycock, Mr. Record, Mr. West, and other local gentlemen, and your obedient servant—J. WRIGHT.

SCHIZANTHUSES FOR SPRING DECORATION.

ALL, I think, who have seen these beautiful annuals well grown will admit their beauty. There is no mode that I am aware of at all comparable for bringing out the full beauty of these plants equal to that of sowing the seed towards the end of the present month, and growing and flowering the plants in pots in the greenhouse or conservatory.

The finest examples of culture that I ever remember having seen were grown by your veteran aparian contributor Mr. Pettigrew. It is nearly thirty years since I saw the plants in the excellently furnished conservatory at Cheetham Hill near Manchester, and they haunt my memory still. They were dazzling masses of beauty some 4 feet high and 3 feet through, and were produced in fruiting Pine pots. For elegance combined with brilliancy I have never seen plants to equal those. I have grown plants frequently after the same fashion, but specimens of equal size to those referred to I have never been required to produce. I have been in the habit of flowering the plants in 7 and 8-inch pots, which have been fully large enough for the structure in which they were arranged. Other plants were wintered in 5-inch pots and planted out in the mixed borders of the flower garden, and during the months of June and July few, if any, plants in the garden were more admired.

The plants are of easy culture. The treatment usually given to Mignonette suits them admirably. The great point is to sow the seed thinly and never at any time to permit the plants to become drawn. Before they touch each other in the seed pots they should be thinned. If only small plants are required to flower in 48-sized pots the seed should be sown in 60-sized pots, allowing three or four plants to remain in each pot. If large brilliant bushes are required sow the seed in 5-inch pots, and leave from seven to nine plants in each according to the size of pots the plants are to be flowered in. One shift before winter is usually sufficient, or, if necessary, the plants may be wintered in the seed pots. After sowing the pots should be placed in cold frames, but the lights should be drawn off on every favourable moment, and especially at night when the weather is settled. The best mode of wintering them is to plunge the pots in ashes in a pit or frame having a southern aspect, the plants being close to the glass and protected from frost.

Early in the spring, when fresh growth commences, they require shifting and to be placed in the lightest and best ventilated position at command, yet must be secure from severe frosts, which at that period of the year are often prevalent. They thrive best in soil that is rather light but rich, and after the blooming pots become filled with roots clear weak liquid manure given twice or thrice a week is highly beneficial; copious supplies of water are imperative. If the plants are neglected in this respect the foliage assumes a sickly hue, and not only mars the beauty of the plants, but impairs the size and colour and shortens the duration of the flowers. Given the treatment required, and it is simple enough, few plants will be more attractive in May and June than these gay yet chaste and too-seldom-seen annuals.

All the varieties are worthy of culture, a few of the most effective being *retusus* and its white variety *albus*; *papilionaceus*, quite butterfly-like; *pinnatus grandiflorus*, and *Walkeri*. If I were growing only one variety I should choose *retusus*.—J. W. S.

ST. SWITHIN PEAR.

To the many achievements in the way of raising new fruits the Sawbridgeworth Nurseries have added a new early Pear

which will add to their well-won reputation. The earliest of all Pears is Doyenné d'Été, a small kind which decays as fast as it ripens, and which if not gathered rather before it ripens on the tree is little better than worthless. The new Pear, which has been called St. Swithin from its ripening in the middle of July about St. Swithin's day, is superior to Doyenné d'Été in every respect. It is larger, it keeps longer after being gathered, and it is of superior flavour.

Fig. 20.—St. Swithin Pear.

The fruit is rather below medium size, obovate or pyriform, the two forms being shown in the accompanying illustration. Skin smooth, grass green, thickly dotted and mottled with russet and sometimes with a faint brown blush on the side next the sun. Eye small and closed, with incurved tooth-like segments set even with the surface without depression. Stalk from half an inch to an inch in length, inserted without depression. Flesh yellowish white with a greenish tinge, tender, juicy, and sweet, with a fine brisk flavour.

St. Swithin Pear was raised from the *Calebasse Tougard*, a remarkably prolific Pear. The seedling has the same characteristic. It ripened in an early summer by the 16th of July, but this year it was later. The growth of the tree is not vigorous, but it forms a compact pyramid. The flavour of the fruit is more sprightly and brisk than the Doyenné d'Été. Altogether it will be found a pleasant addition to the summer garden Pears.

A VISIT TO THE EXETER NURSERIES.

FOR some time I have been intending to write an account of a visit I paid to the extensive nurseries of Messrs. Lucombe and Pince at Exeter, but the pressure upon your space has of late been very great, and I have been very busy; but now that the great shows are over, and that autumn flowers alone attract attention, a few notes upon the subject of my visit may be acceptable.

As many of your readers are aware the sole proprietor of these nurseries is Dr. Woodman. There is no Lucombe and no Pince, though on one occasion Dr. Woodman averred the contrary.

On the evening of one of the most successful Rose shows ever held, whether at Exeter or elsewhere, Dr. Woodman was returning home from the hospitable abode of "Hercules" when he suddenly became convinced that a fire of some magnitude was raging near his place. He asked a bystander where the fire was. "They say it is at Pince's," was the reply. "Pince's! What do you mean by Pince's? I am Pince." His stables

fortunately alone suffered on that occasion, and his extensive collection of plants was saved.

This is indeed a grand assortment of Flora's gifts. It extends to nearly every species of flower, beginning with stove and greenhouse plants and ending with hardy Alpines and herbaceous plants. He has a great amount of glass, all constructed in a plain useful manner, which says, as plainly as if it spoke, "We mean business, not show."

On my arrival I was joined by that enthusiastic florist the proprietor, who took me round everywhere, and in the evening drove me to his distant nursery at Exminster. It would take up too much of your space were I to attempt to describe to you half of what I saw. I can only give you a few details as to the most striking features of the place.

First, the houses are full of young plants in a most flourishing state, but the grand specimens which took London by storm at the Westminster Aquarium no longer grace their old home. They had become too big for their home. The children had outgrown their cradles and required rocking chairs. Dr. Woodman would have had to build new houses for them, and this he did not feel inclined to do, so he sold them, and at the Crystal Palace and Kensington I have recognised old favourites that once smiled down on the fair lasses of Devon at Northernhay. But though the giants have sought new hunting grounds, yet their children remain to keep up the reputation of their old home, and a nicer cleaner lot of young stuff I never saw.

I need not dilate on Allamandas with their golden flowers, or Bougainvilleas with their sheen of dewy pink, or seek to tickle your readers' ears with descriptions of Dipladenias and Ixoras. I can leave the charms of the virgin *Eucharis* unsung, or the pure waxen blooms of the bridal *Stephanotis* uncelebrated. I can simply say that all the flowers, the names of which are household words among florists, were there in all their beauty.

And now let me go outside and tell your readers of the rock garden. This was to me a perfect wonder. It exceeds all I have ever seen. It is finer than the one in the Battersea Park, and could not in my opinion be excelled. How any man could go to the expense and trouble of making that maze of rocks and winding paths when there was nothing in a trade point of view to be gained by it passes the comprehension of many who see it. But the late Mr. Pince had a soul above such a low consideration; he was a true horticulturist at heart, and lavished his money and labour upon what was to him a work of love. You may wander in that rock garden in the noon heat of a summer day, and you will be as cool as if you were sitting by the sad sea waves; you may stroll about and admire the Alpine plants, and Ferns, and *Lycopodiums* which abound, and forget altogether that within 20 yards of where you are is the great high road to Exeter; you may bend down and see your ugly face reflected in a pool of limpid water where the Water Lily and other aquatic plants, like the mermaids or syrens, seem to woo you to kiss them, and within two miles of you is the metropolis of the west, the lovely city of Exeter. The botanical student may spend hours and days, and yet find plenty to learn when he had done. The Editors of this Journal would be enchanted with it if they would but come so far, and would be the better for a few hours or even minutes spent there.

In the general nursery the most prominent features are the pinetum and the Italian garden. The numbers of fine Pinuses—*noobilis*, *insignis*, *austriaca*, and *excelsa*—would delight the lover of these grand Conifers, while the numerous specimens of Golden Yew and *Arbor-Vitæ* would enchant the painter with their rich colour and shapely form.

Dr. Woodman is also a cultivator of the Rose upon (I hope he will forgive me, but I am trying to describe truthfully what I say) a small scale. He has evidently the wish to grow good plants, but up to the present he seems to have had bad luck. His rows contain more failures than are usually seen in first-class nurseries, but he intends to persevere, and no doubt will soon succeed, and be in this, as in many other departments, *nulli secundus*. He has, however, a fine collection of *Niphetos*, which he finds so useful for bridal bouquets and cut flowers. While I was there Sisters of Mercy were wandering through the houses collecting flowers for the altar vases of their chapel, and they find *Niphetos* a most valuable Rose.

A small space in the nursery is devoted to hardy herbaceous plants. Here may be seen excellent specimens of *Delphinium*, *Dianthus* in its various species and varieties, *Phlox*, *Pentstemons*, &c., and the proprietor is commencing to form a good collection of Pansies.

Here, as elsewhere, I met with the greatest kindness and hospitality from the owner, and I shall hope before the winter to pay him another visit.—WYLD SAVAGE.

ROYAL HORTICULTURAL SOCIETY.

AUGUST 20TH.

ALTHOUGH fruit, plants, and cut flowers were exhibited they were not represented in large numbers, and the meeting on the whole was not a large one; yet several of the exhibits were of great merit, and first-class certificates were awarded accordingly.

FRUIT COMMITTEE.—Mr. W. Paul in the chair. The following fruits were brought from the Society's garden at Chiswick—Early Silver Peach from a wall, one of Mr. Rivers's seedlings. The fruit was large and more highly coloured than usual. It was of fine flavour, and as an early variety one of the most desirable. Auguste Julie Pear, an early variety ripening in the middle of August; a crisp-fleshed, juicy, sweet, and finely perfumed variety, coming into use at the same time as *Beurré Giffard*. Mr. Francis Dancer, Little Sutton, exhibited dishes of Rivers's Sultan Plum raised by Mr. Rivers. It is a valuable early Plum, excellent bearer, and vigorous grower. It was awarded a first-class certificate. Also a good dish of Victoria Plum. A letter of thanks was awarded for the collection. A collection of Russian Apples was sent from the garden at Chiswick, none of which was worthy of cultivation. Messrs. William Paul & Son of Waltham Cross sent fourteen dishes of early Apples, to which a letter of thanks was awarded.

Mr. Coleman, Easton Castle, sent a red-fleshed seedling Melon called Dr. Hogg, raised by Mr. R. Gilbert, Burghley, but it was not of sufficient merit to warrant a certificate. Mr. Henry Prinsep, The Gardens, Buxted Park, Uckfield, sent a seedling Melon called *Beswick's Hybrid*, but it was not equal to others in cultivation. He also sent another called *Buxted Hybrid* which was not ripe. Mr. Osman, South Metropolitan District Schools, Sutton, Surrey, sent two seedling Melons which were not good. Mr. Fraser, The Gardens, Ashby Hall, Sleaford, sent four seedling Melons, all of which were inferior in flavour. Mr. Hinds, gardener to Sir Thomas Edwardes Moss, Otterspool, sent a fine bunch of Golden Champion Grape which was completely spoiled in the carriage. Mr. J. G. Cheek, gardener to G. D. Clapham, Esq., Great Dunmow, sent a seedling Cucumber called Lord Beaconsfield, which was not better than others in cultivation. Mr. Young of the Milford Nurseries sent jam made of *Elæagnus edulis*, which was considered deficient in pulp.

FLORAL COMMITTEE.—Dr. Denny in the chair. Prominent amongst the plants submitted to the Committee was the grand new Orchid raised by Mr. Dominy, and which has recently flowered in the collection of Messrs. Veitch & Sons. This remarkable variety was alluded to on page 132, and it is only necessary to say now that in addition to its remarkable colour the flowers are deliciously perfumed. The growth of the plant is free and upright, the pseudobulbs being somewhat slender and 5 to 6 inches long, the leaves being 8 or 9 inches in length and 1½ inch in diameter. It is a grand acquisition, and has been named *Cattleya Veitchiana*. A first-class certificate was unanimously awarded for this fine plant.

Sir Trevor Laurence, Bart., Burford Lodge, Dorking, sent a fine plant of *Odontoglossum Reichenheimii*. The pseudobulbs are large, and the flower spike about 5 feet long. The upper half contained the flowers, which are produced on short branchlets and are beautifully marked. The sepals are chestnut colour marked with buff, and the lip purplish mauve tipped with pinkish white. From the same collection came *Dendrobium McCarthiae*. The flowers are very large and drooping; sepals very pale lavender, the margin of the lip being a deeper shade of the same colour; throat violet with a dark bar, and surrounded by a zone of creamy white. A vote of thanks was awarded.

Mr. Mitchell, gardener to Dr. Ainsworth, Manchester, sent a seedling *Cattleya* named *Mitchellii*, the result of a cross between *C. Eldorado* and *C. Leopoldi*. The sepals and petals of the new variety are purplish salmon in colour, the lip, which is rather small, being violet mauve, and the throat orange. The flower is distinct alike in form and colour, and was awarded a first-class certificate.

Mr. B. S. Williams, Holloway, exhibited a small collection of plants, to one of which, *Croton Williamsii*, a first-class certificate was awarded. The plant is a strong grower, with smooth, large, laurel-shaped foliage 8 to 9 inches long and 2 broad. The ground colour is very dark green heavily veined and mottled with crimson. It will make a fine companion plant to *C. undulatus*, but is brighter in colour than that good old variety. A large-leaved variety named *Henryanus*, exhibited by Mr. Williams, was very effective by its fine golden yellow foliage.

Mr. R. Johnson, gardener to T. T. Clarke, Esq., Swakeleys, Uxbridge, exhibited two very fine plants of *Valloas* as seedlings from *V. purpurea*. The flowers are very clear and bright in colour, and the plants are extremely floriferous, one of them having twenty-five spikes. A cultural commendation was awarded by the Committee. Mr. H. Clayton, The Gardens, Grimston Park,

Tadcaster, exhibited a plant of *Blechnum interruptum*, more curious than beautiful, and a botanical certificate was awarded.

Some fine Dahlias were exhibited by Mr. Turner, Royal Nursery, Slough, to two of which, Helen Macgregor and Lord Beaconsfield, first-class certificates were awarded. The former is a flower of great refinement and symmetry; the colour is rosy purple, deepening at the tips of the petals, which are cupped, and in the centre of the flower are nearly white; very chaste and unique. The latter is a very large and massive flower; colour very rich maroon. John Ashby, brilliant scarlet, was very fine; also Amy Robsart, purplish lilac. A creamy white Pompon Dahlia, Lady Blanche, is remarkable by its much-cupped almost quilled petals; it is very distinct. Messrs. John Laing & Co., Stanstead Nursery, Forest Hill, exhibited Begonia Mrs. J. H. Elwes. It is of the B. Pearcei type, and bears some resemblance to B. Moonlight; free and attractive. Mr. H. Cannell sent a splendid collection of thirty-six varieties of Verbenas; both trusses and pips were extremely fine, and almost every shade of colour except yellow was represented. A vote of thanks was deservedly awarded. Mr. Cannell also sent some well-marked French Marigolds.

Mr. G. F. Wilson, F.R.S., sent cut blooms of *Lilium Leeshmanni* having a slender stem, narrow leaves, and a richly spotted flower; also the true and beautiful *L. lancifolium rubrum*, which is one of the best Lilies in cultivation. It was greatly admired, and the thanks of the Committee were voted to Mr. Wilson. Mr. Green, gardener to Sir G. Macleay, Bart., Pendell Court, Bletchingley, sent some very fine flowers of Begonias grown in the open border; also a hybrid *Nymphaea*, Regina; *Gladolus dracocephalus*, and a species of *Carica* having pure white Bouvardia-like flowers in umbels and immense palmate leaves, one of them being 2 feet in diameter. A vote of thanks was awarded. A similar award was granted to Mr. Yates, Sale, Cheshire, who sent a fasciated spike of *Lilium auratum* containing about fifty flowers. Similar examples have frequently been produced in Mr. McIntosh's fine collection at Duneven.

From the Society's garden at Chiswick came a collection of Abutilons and cut blooms of *Phlox Drummondii*, *Dianthus Hedewigii*, Zinnias, and Asters. The most distinct and useful of the Abutilons are Lemoinei, yellow; Boule de Neige, white; Rosæ-florum, rose; Beranger, striped; Vexillarium, crimson, foliage variegated, and branches drooping; and Darwini tessellatum, foliage finely marked and flowers good.

GENTIANAS AND THEIR CULTURE.

INQUIRIES having reached us relative to Gentians and their culture, we extract the following from Sutherland's "Hardy Alpine and Herbaceous Flowers," an excellent work published by Messrs. Blackwood & Sons, which treats fully and soundly on the subject to which it is devoted:—

"*Gentiana* (Gentian).—An extensive genus, comprising some of the loveliest of hardy herbs. The species are mostly inhabitants of alpine homes; some of them, indeed, flourish well only at the utmost limits of vegetation on the great alpine ranges of the world and the arctic regions, and such are difficult to cultivate for any length of time, however closely the circumstances of their wild homes may be imitated; but they are not a numerous class, though they certainly are in a few cases amongst the most brilliant of the genus.

"Another group, more numerous and less difficult to manage in cultivation, are found in nature to prefer high mountain pastures, dry or moist, in gravelly soil in which vegetation is scanty, and in deep rich alluvial earth or peat where plants become comparatively luxuriant and more numerous. These are the most useful species, because the least fickle and coy under the restraints of cultivation; and amongst them the brilliancy of the finest of the high alpine genus is closely approached.

"All that may be cultivated in beds or borders flourish well in light, rich, sandy loam; well drained it should always be, but during the growing season at least it should be also moist. The high alpine species, requiring rockwork or pots, flourish in the same soil if the addition of a little peat and a good deal of gritty matter is made to it; but the more special requirements of these will be alluded to hereafter more particularly. They are propagated by division and by seed. The former is a simple method with such species as verna and acaulis, which form turf-like masses not easily destroyed when cut up into even very small bits; but with such as lutea more care is necessary. It and some of its allies form deep descending roots and thick rootstocks or crowns, composed of only a few centres of vitality in even long-established plants, and they should not therefore be reduced minutely. Division should be done in early spring as soon as growth commences actively. Propagation by seed is a very tedious business, requiring some facilities in the shape of cold frames or handlights, and involving some considerable exercise of care and patience; but when large increase of those sorts that are difficult to divide is determined upon, seed must be resorted to as the only means whereby it can be obtained.

"The seed of most of the Gentians is slow to vegetate, especially

if it may have lain some time in papers or in store; but if it can be sown immediately it is ripe some saving of time will be gained. The possibility of doing this will depend on whether the seed has been saved at home or purchased from the seedsman; if the latter, then it will be at least a year before the majority of the seeds germinate. But many of the cultivated species seed freely, and advantage should be taken of this circumstance by sowing them as soon as they are ripe, when the greatest bulk of them will vegetate the following spring or early summer. The compost already spoken of is the best to sow in, using perhaps a more liberal allowance of sand, and the whole may be passed through a coarse sieve. Small-sized pots are the best—say 4 or 5 inches—because the most handy to move; and what is of more importance the smaller mass of soil is less liable to become sodden than that which is larger. The pots being well drained must be filled with the compost, pressing it firm and level in the process. Sow the seed thin and cover lightly; fix the labels and water gently, and plunge the pots to the rim in coal ashes in a cold frame. The only attention they will require for the remainder of the season, supposing the sowing to be done in summer or autumn, will be that of shading so long as the day is long and the sun strong, admitting air sufficient to keep the frame cool, and watering as it appears necessary, and that will be necessary always when the surface of the pots appears somewhat dry. On winter setting in, the frame will require to be protected during severe weather, but on all favourable days air may be admitted freely. On the approach of spring the pots should be examined, any mossy growth that may have made its appearance removed, and a slight sprinkling of fresh soil given along with a gentle watering to finish, when they may be returned to their quarters again. The admission of air so as to keep up a nice temperature in the frame and yet prevent excessive heating, a slight shading as the day lengthens and the sun's rays increase in power, and careful watering as required, are the only points essential to be observed till the plants begin to appear, but the shading should not be used except on bright days, and then only for an hour or two during the hottest part. When the plants appear in reasonable quantity it will be necessary to gradually inure them to more light and air; and while they are yet small and tender they must be carefully handled as regards watering: one rude dash of chilly water may cost the lives of hundreds of tiny plants. When they are fit to handle they must be pricked off into pots or boxes, or, what is better if at hand, they may be turned into a nursing bed or shallow frame in suitable compost, pricking them out an inch or two apart each way.

"The majority of perennial Gentians make but little bulk the first season from seed, and to turn them out of doors in permanent quarters the first winter would be to court disaster; their enemies, in the shape of slugs and other vermin, would soon make short work of their small development of leaf and stem, and the action of frost mechanically on their tiny root-hold would be too trying an ordeal for them to pass through successfully. It is necessary, therefore, to winter them compactly together where they may be protected when required, and where vermin when they appear may be easily given good account of. If frames or handglasses cannot be spared for them a bed of coal ashes kept together by an edging of bricks or boards in some sheltered spot will do very well to winter in, the pots being plunged as much over the rims as is consistent with the safety of the plant, and a few hoops arched over the bed will furnish a suitable framework to support the protecting materials. The plants may be turned out into their permanent places the following spring."

(To be continued.)

TAUNTON DEANE HORTICULTURAL SOCIETY.

AUGUST 15TH.

WHENEVER I want to express my ideas as to how a society ought to be worked and how the public ought to encourage it, it is my custom ever to refer to Taunton as one of the very best examples I know of; and this year not only was no exception to the rule, but it seemed to me to be in advance of those I have previously seen, and I think this is the sixth. The whole town was as usual *en fête*. Large Spruce trees had been cut and planted in the market-place and other localities; there was a large display of bunting; stalls containing such a variety and quality of comestibles as makes one more and more admire the digestion of the Somersetshire yokels, who seemed to go in indiscriminately for whelks and peppermints, pigs' feet and green Plums. Then the gentry of the neighbourhood, instead of holding coldly aloof, not only encourage it by their subscriptions but attend in great force during the day, so that it is no easy matter to get to one's carriage when the gates are closed. Contrast this with our miserable east-country proceedings. There is Canterbury without a society worthy of the name, while other towns have associations which are fully supported and patronised.

The Exhibition was both excellent in quality and large in extent, and I think the supporters of the Society have great reason to congratulate themselves. I have seldom seen a show at which fewer things of bad or indifferent quality were exhibited. The

system of only giving two prizes in each class, although having its objectionable side, does doubtless discourage people from sending indifferent things, as they feel they would have but little prospect of gaining a prize. On this occasion, too, there was no padding—that is, no plants sent in not for competition. Messrs. Lucombe & Pince, having given up exhibiting, were not present, while the awfully sudden death of Mr. Bryant of Bristol prevented his plants from being there; so that it will be seen that there must have been good strength put forth by exhibitors to make such an excellent show. Mr. Cypher was there with his beautifully finished plants, so clean, neat, and well grown; so was Mr. Tudgey, gardener to Mr. Williams of Worcester; while amongst amateurs Mr. Marshall of Belmont occupied the foremost place. His plants were exceedingly well grown, and some of our best and newest introductions were to be found amongst them. The Roses of Mr. Prince of Oxford and the Dahlias of Mr. Dobree were very fine, but we missed altogether the Gladioli of Mr. Kelway. It was indeed a loss, especially to me, as I had hoped (not having been able to stop at Langport, although I passed it) to have seen some of his famous seedlings, but he was not there. Zonal and other Pelargoniums were exhibited in a manner that other places nearer home might well copy; not huge overgrown masses, all hoops, sticks, and ties, but neat compact little bushes, full of bloom and fresh and lively. There was a good display of fruit and a most excellent collection of vegetables, while the cottagers' productions were worthy of all praise. But I think the most marked improvement that I saw was in the table decorations and bouquets. I remember animadverting on these last year, when only two very miserable attempts were exhibited; this year there were five, and of these four were highly creditable. When I say that Miss Cypher took the first prize it will be readily conceived that all that good taste and deft hands could effect was done, and the result was charming. The centre of the table was a nice plant of *Cocos Weddelliana*: the two end pieces being glass stands light and elegant, and the flowers arranged in them being also very elegant and lightly arranged, amongst them sprays of *Francoa racemosa* being very freely used, and a most capital flower it seems to be for decorative purposes. *Plumbago capensis* was also used, and its delicate light blue tint of colour is always attractive. The other three tables were also arranged in good taste, and exhibited a most striking contrast to those of last year. The drawing-room stands were also good, while Miss Cypher's bouquet with its flowers of *Pancreatum* attracted universal admiration. It is not always that so unanimous a consensus of public approval is given to a successful exhibition of table decorations as was given on this occasion to Miss Cypher.

The courtesy and kindly feeling which are always shown at Taunton were not absent on this occasion. Mr. Clement Smith, the able and indefatigable Secretary, and the members of the Committee vied with one another in making everything go pleasantly, and I am sure felt amply rewarded by the success that attended their efforts. I cannot close these few notes without mentioning a laudable attempt to turn the day to good account—the opening of a coffee stall in the town, which seemed to have secured a large share of patronage, and in which the ladies of the house where I was staying (Mr. Newton's of Barton Grange) took a lively interest. They sent in a large number of button-hole bouquets, which were sold at 1d. each, and sold well, one gay Lothario having purchased eleven. Talk of two strings to their bow, what is that to a beau with eleven —? So that altogether promoters of flower shows would do well to take a lesson from Taunton.—D., *Deal*.

RHODODENDRON OCCIDENTALE.

ONE of the grandest flowers I ever beheld is the *Rhododendron occidentale*, or Californian Azalea. It is a native of California, where it grows along streams of crystal water in thickly wooded districts throughout the State. The finest are found in the Sierra Nevada, and the best I ever saw were in the section of county around the Silver Creeks, where they are covered with snow for four months in the year.

Rhododendron occidentale is a shrub growing 3 to 6 feet high; the foliage is the handsomest I ever saw. The leaves are lanceolate in shape, about 4 inches long, and 1 to 1½ inch across, of a rather firm texture when fully developed; in colour they are a bright shining green. When half grown they have all the appearance of being freshly varnished, and, as will be readily admitted by all who have seen it, this bright green foliage is half the charm of the plant, and makes a most charming setting for the large and conspicuous flowers.

The flowers are 2½ to 3 inches long, with a conspicuous calyx composed of distinct oblong sepals; the corolla is usually snow-white with the upper lobe yellow inside. They are sometimes, however, found with rose-tinged flowers. The stamens and style are much exerted, moderately curved, and very conspicuous. The flowers are borne in large clusters of from ten to twenty each. *Rhododendron occidentale* blooms

in the summer, and is constantly in flower during July and August.—W. C. L. DREW (in the *American Gardener's Monthly*).

REVIEW OF BOOK.

The Bulb Garden. By SAMUEL WOOD. London: Crosby Lockwood & Co.

MESSRS. SPOTTISWOODE can print books better than Mr. Wood can write them. The very title of the book is a misnomer, for it implies that all the plants treated of are bulbs, whereas in fact only a very small portion of them belong to that category. The author himself reminds us that it is through ignorance that he has dragged in so many plants under the title, for he makes a sort of quasi apology in the case of one plant, *Saxifraga granulata*, which he says "can scarcely be classed in the category of bulbs, yet it is a bulb." There is only one way of meeting a distinct assertion of that kind which is calculated to mislead, and that is by a distinct denial. *Saxifraga granulata* is not a bulb, but a hardy herbaceous plant, producing small granular tubers. As no apology is advanced, nor excuse made for including other plants under the heading of bulbs, we can only conclude that the author does not know what a bulb is. He appears ignorant of the very rudiments of his subject, and ought not to be encouraged to circulate a mass of inaccuracies. *Lychnis fulgens* is described as a "tuberous-rooted bulb," whatever that means, whereas it is a hardy herbaceous perennial. Then alluding to the Winter Aconite the author remarks that "it is almost superfluous to write about this common, little, hardy, 'bulbous' plant." It is a not a bulb at all, and we must say that we never saw it associated with more sentimental rubbish than in this book. The author claims above all things to be plain and practical, but the Winter Aconite appears to have prompted him to try his hand at poetry, for we find amongst more of the same character such lines as these:—"Ah! pretty little flower, let no one ever despise thee on account of thy smallness or colour. Thou hast a voice like the Rose or the Lily, or the less gay songster among the feathered tribes." Then we have amongst other "bulbs" chapters on the Hepatica, the Hellebore, the *Dielytra*, the *Agapanthus*, the *Calla*, the *Lily of the Valley*, *Solomon's Seal*, and other herbaceous perennials. Then *Cyclamens*, *Begonias*, *Irises*, and even *Ponies* are included; it is a wonder that *Primroses* and *Violets* were not added, but perhaps their omission was an oversight.

We regret very much that any gardener should have been tempted to display his want of knowledge by compiling such a book as the one before us, for it cannot but convey to the general public who read it much that is flagrantly erroneous, and which ought never to have been published.

As to the practical portion of the volume, we have only to remark that equally good information is supplied gratis to purchasers of bulbs in the catalogues of the principal nurserymen and seedsmen. Amongst other things we are told that £2500 per acre can be realised by growing *Hyacinths* in England—information, we presume, for the "speculative professional man" referred to in the preface. Modern cultivators will wonder that no mention is made of the value of *Solomon's Seal* for forcing in the chapter on that plant, and they will smile at the display that may be made by planting three *Triteleja* bulbs in a 48-pot, knowing that three times three are necessary; but compensating information is supplied in the sentence that *T. uniflora* may be planted in "dwarf beds."

But while many plants are included in the "Bulb Garden" that are not bulbs there are omissions of other plants that might legitimately have had a place in the book. Snowdrops are mentioned, but not *Snowflakes* (*Leucojums*), neither are *Roman Hyacinths*, *Muscari*, *Lachenalias*, *Tritonias*, *Guernsey* and *Belladonna Lilies*, *Tigridias*, *Antholyzas*, *Cyclobothras*, &c., all of which are popular decorative plants of the type which one might expect to have found mentioned in a book of this description.

We have referred to this book at greater length than we otherwise should have done in order to convey warning to those who may be really good practical gardeners not to jeopardise their reputations by attempting to write on subjects that they do not understand. We cannot join the author in recommending the book either to the "amateur or the speculative professional man."

SEXUAL CONDITIONS IN THE RED MAPLE.—It is commonly stated that Maples bear hermaphrodite (male and female) flowers, but Mr. Thomas Meehan of Philadelphia

asserts that the Red Maple is, according to his observations, really dioecious, having only flowers of one sex on the same tree. But the male and female flowers are similar in outward appearance at first opening, except that the small pistil is not developed in the male flowers. The female flowers have anthers of full size, and are supposed to be of both sexes, but the fact is that the anthers do not develop after the flower has opened, and shed no pollen. This is a very remarkable survival from a condition when the flowers were perfect. It is not uncommon to find trees originally female sending forth male branches, but Mr. Meehan has not found male trees produce female branches. The male flowers were found fragrant, the female not so.—(*Nature*.)

DENNSTÆDIA DAVALLOIDES YOUNGII.

SEVERAL months ago I purchased a plant of the above Fern, or rather a Fern bearing the above name, for I am now in

doubt whether my plant is rightly named. When it was received it was in a small pot, and was dwarf in growth and had very finely cut bright green fronds. The plant was potted in a mixture of turfy loam, leaf soil, and charcoal—no peat—and was grown in a moist shaded place in a cool stove or intermediate house. It has grown with great luxuriance, and instead of being a low-growing *Davallia*-like plant as I supposed it would be, it almost as much resembles an *Alsophila* but without its coarseness. I have asked the advice of two neighbouring gardeners and am now more puzzled than ever, for one says my plant is true and the other that it is not. Fronds are produced nearly 4 feet long and with very thick stems, which grow nearly upright and then arch gracefully. I am not disappointed with my plant, for while it is robust it is yet elegant; but my doubt is that it is true to name. Can you enlighten me?—W. B. L., *Lancashire*.

[We think your plant is correctly named. *Dennstedtia davallioides* Youngii is a stately-growing yet graceful Fern,

Fig. 21.—DENNSTÆDIA DAVALLOIDES YOUNGII.

as the accompanying truthful engraving, obligingly sent to us by Mr. B. S. Williams, sufficiently represents.—EDS.]

NOTES AND GLEANINGS.

By what we have seen in more places than one we are satisfied that a word of warning is necessary against withholding water to such an extent, as appears yet too common, from the roots of VINES IN POTS with a view of ripening the canes. Only evil can result by permitting the foliage to flag and become prematurely brown by allowing the roots to become excessively dry. The roots must be kept in a fresh healthy state, and the leaves should be encouraged to retain their green hue, and their change should be as gradual as possible. With heat, light, and air the canes will mature admirably without drying the roots extremely, and plumper

buds in autumn and better bunches in spring will result than if the Vines have been erroneously checked and starved with the view of accelerating the maturation of the wood.

— ONE of our contemporaries, who is distinguished for his hypercriticism and occasional abortive attempts at wit, tells his readers that "whatever may have been the riches of the Hanging Gardens of Babylon, it is pretty certain that, all things considered, they were not excelled by what may be seen in some of the west-end squares." He then counsels his readers to visit "an area decorated with a dozen hanging baskets variously furnished." (!) We often hear of descents from the sublime to the ridiculous, but a greater descent could hardly be imagined than to compare the glorious terraced gardens of Babylon with a dozen hanging baskets in a west-end London area—a dozen of the "biggest Gooseberries" we have heard of this year.

— WE never remember having seen FOREST TREES so green and luxuriant in harvest as during the present year. Having recently traversed the district of Cobham Hall near Gravesend we could not fail observing the exuberant foliage of the fine avenue of Elms in Lord Darnley's park. The country lanes, too, on the Cobham estate are now extremely beautiful, the foliage of the trees of the woods on either side completely arching the roads, forming refreshing canopies of foliage, and the trimness and neatness of the roads and hedges impart additional pleasure to the visitor driving through this beautiful and richly wooded district. All kinds of trees appear to thrive equally well; but especially noticeable are the Sweet Chestnuts, many of which are bearing good crops which ripen, and are collected for the deer in the park. A portion of the undergrowth of the trees consists of Rhododendrons, and the appearance of these shrubs and the manner in which they bloom in the spring afford evidence that they are about the best of all evergreens for growing under the shade of trees.

— FROM Cobham above mentioned a pleasant drive leads to Gads Hill, where the residence of England's great novelist, the late Charles Dickens, is the centre of attraction. CHARLES DICKENS' GARDEN is small, but evidently has been, and is now, cherished. The house stands back some 40 or 50 yards from the public road, and the front up to the bay windows is staged for accommodating pots of scarlet Geraniums. At the extremity of the lawn next the road is a thriving pair of Deodars which had probably been planted by the late owner, and the garden on the opposite side of the road contains a grand pair of Cedar of Lebanon, also flower beds and ornamental shrubs. A subway formed under the road connects the two gardens, which are in excellent keeping, and are not less enjoyed by the family in residence than by the thousands of visitors who pay a passing glance at the home of one whose name will be cherished long after the trees that he planted have crumbled to decay.

— IT has frequently been stated that, provided VINES have good attention, they will yield good crops when no specially prepared border has been formed for the roots. A good instance of the truth of this is afforded by a large vinery at Coombe Bank. When the house was erected it was intended for plants, but Mr. Moorman decided to try some Vines as well. Several varieties were planted in the ordinary garden soil. During the growing season the soil was top-dressed with manure, and abundance of water was given to the roots. The result was splendid canes, and a crop of remarkable weight was produced the following (this) season. The canes made this year are also excellent, being as thick as a man's thumb and studded with bold eyes. The soil is light and gravelly, such that grows Conifers and Hollies splendidly. The health of the Vines is no doubt attributable to the manurial top-dressings and heavy waterings, efficient drainage being secured by the natural porosity of the soil. The Vines are probably as good as they would have been if the most expensive and elaborately prepared border had been made for them.

— THE quantity of SCARLET RUNNER BEANS now being sent up to the London markets is very extraordinary. One salesman in Spitalfields Market receives upwards of a thousand bushels weekly from one parish in Essex. The variety of Runners fetch better prices, are more productive, and consequently on the whole more remunerative than the larger varieties of the Champion type—a fact intending growers for market ought to take note of.

— A CORRESPONDENT, "G. H. V.," writing from Retford in reply to Mr. Godward on page 132, states that EUCALYPTUS GLOBULUS, about 12 feet high, has been in magnificent flower this year, but both of the trees are now dying, and he has seen the like at Garnons, Hereford. — In reply to F. Finch we can say confidently that in England Eucalyptus globulus is a rapid grower, and Mrs. Brassey informs us in her "Voyage of the Sunbeam" that in Tenerife a specimen grew 115 feet in seven years.

— MR. COSSOM, gardener to Mr. Campbell-Bannerman, M.P., at Hunton, Kent, tells us that a LYGODIUM SCANDENS, started into growth at the middle of January, completed by the beginning of May an aggregate growth of 384 feet. The plant was potted into a 13-inch pot in the early part of 1877, and has not been potted since. The longest separate growth is 16 feet 6 inches.

— THE Round-leaved Maple, ACER CIRCINATUM, Pursh, is, says the "Journal of Forestry," one of the most effective and striking of hardy deciduous trees of a medium size. It

was introduced to Britain in 1826 from the north-west coast of North America, where it grows to a height of from 30 to 40 feet. It is easily distinguishable by its regularly fan-shaped leaves, which are deeply cut into seven or nine sharply pointed lobes, and when first expanded are of a lovely reddish green colour. Its flowers are produced in May in considerable profusion, the petals being pure white, in fine contrast to the deep red of the sepals and long peduncles. The bark of the young shoots is also of a reddish colour, and in the autumn the leaves acquire a beautiful tinge of yellow and red as they ripen and decay. The branches are of a slender and pendulous habit, giving character to the tree in winter. Planters on the look-out for a moderate-sized ornamental tree would do well to devote some attention to this beautiful Maple, which will grow well in most parts of the country.

— No one, says "The Gardener," and we fully concur, who has a demand for decorative plants and cut flowers all the autumn and through the winter, should neglect the good old CYPRIPEDIUM INSIGNE: it is so hardy and accommodating, flowers so freely, and lasts so long either on the plants or when cut. We have this variety in all sizes of pots, from 14 inches down to 5 and 6 inches, bearing from three to four dozen blooms in a plant to five or six, according to the size of plants. No plant or flower bears the atmosphere of a sitting-room better, consequently it is invaluable for room decoration.

— FOR covering the wall of a stove densely and closely few plants are better adapted than FICUS REPENS MINIMUS. We recently saw a wall in the gardens of N. Clayton, Esq., Lincoln, covered with this Ficus, and the effect produced was extremely chaste. The small leaves and shoots adhere to the wall as tenaciously as if they were glued there, forming a smooth dark green surface that cannot fail being admired. But although this plant covers the wall of a stove so well, it will thrive in a cooler temperature; indeed, we remember having seen in Mr. Kinghorn's nursery at Richmond some sprays that had forced themselves from the interior of the stove through crevices in the brickwork, and were clinging healthily to the wall outside, where they had passed the winter uninjured. The plant also appears to thrive well in shaded positions.

— ASPARAGUS GROWTH, says a correspondent, at this time of year ought to be more generally used for working-in with cut flowers in vases, &c. It is also admirably adapted for covering archways and pillars at harvest thanksgivings, flower shows, &c. One of the prettiest effects imaginable can be obtained by using Asparagus, the side shoots of the variegated Maize, Asters, and Dahlias for an archway. They not only look remarkably light and pretty, but also last well. The Asparagus should be allowed to hang naturally, the main stem only being tied, and where too long should be cut into shape. If the growth is cut discriminately the plant is not injured, but is rather benefited by the thinning.

— FROM an excellently compiled table on the PICEA NORDMANNIANA by Robert Hutchison of Carlowie we observe that the highest tree noted is at Whittinghame, East Lothian, where it grows at an altitude of 340 feet, in a reddish clay soil upon a subsoil of red sandstone naturally well drained. It was planted twenty-nine years ago, and is now 60 feet high, with a circumference of stem at 3 feet from the ground of 4 feet, and is very healthy and vigorous, and branched to the ground. The next tallest tree amongst those noticed are at Kilravock Castle, Inverness, 50 feet 3 inches high; Dunmore, Stirlingshire, 50 feet high; and Bicton, Devonshire, 48 feet high. In advocating the more extensive planting of this valuable Conifer in our woods and plantations Mr. Hutchison observes: "It will be found most profitable and advantageous to use seedling plants reared from the cone in home plantations; indeed, this is true of all the new Conifers. They suffer less from spring frosts when planted out into the sites they are destined to occupy direct from the seed beds in which they have been reared than plants do which are fetched from a distance, and which we find it requires years to acclimatise in their new homes, leading to many failures, loss of leaders, and to a host of other drawbacks, which do not arise in the use of home-grown nursery seedlings."— (*Journal of Forestry.*)

WORK FOR THE WEEK.

KITCHEN GARDEN.

Sow Lettuce to stand the winter for spring use of the varieties enumerated on page 114. If the ground be light and rich it should be well trodden before sowing, as the plants are not only hardier

but form better hearts than when grown in loose soil. An open yet sheltered situation should be chosen, and to save transplanting sow in rows a foot apart, thinning the plants to 9 inches distance. In cold localities sow on warm borders, or transplant thereto early in October. If sown about a foot from the base of a wall with an east aspect and thinned to 9 or 12 inches distance apart they stand much better than in the open during a severe winter. A sowing of Cauliflowers should also be made in an open situation for pricking off in frames or under handlights in October. Dwarf Erfurt Mammoth, Early London, and Walcheren are those we give preference to for this sowing. Good breadths of Lettuce should be planted for autumn and winter use, also Batavian and Curled Endive, taking advantage of dry weather to tie-up Endive in a sufficiently forward state; also Cos Lettuce, which is liable to grow open at this time of year. Any strong plants of Cauliflower may still be planted, and if the autumn be mild they will be serviceable for lifting when the heads are 3 or 4 inches across, and planting in frames, &c. Let all ground falling vacant from crops of Peas, Beans, Potatoes, Cauliflowers, &c., be cleared and occupied with Winter Greens, saladings, or there is yet time to secure a crop of Turnips by selecting the early varieties; the crops, however, should be of such a kind as will not interfere with next year's cropping. Onions are ripening-off earlier than usual, and may have the tops laid down for the sake of appearance; but it will not alter the size of the bulbs, indeed those that keep the heads erect the longest afford the largest bulbs, yet bending down facilitates ripening. Cut, if not already done, herbs for drying, in order to have plenty to meet any demands that be made for them during the winter.

FLOWER GARDEN.

Carpet beds, whatever objection may be taken to them, are now in great beauty. This style of bedding is becoming more popular every year, and will be more popular still, inasmuch as many of the plants do not require nearly so much care and attention in wintering as Pelargoniums, &c. Sedums, Saxifrages, and Sempervivums are quite hardy, as also are many others, whilst those that are tender need only be wintered as stock plants, and propagated from to almost any extent in spring. Propagation of many of the plants may now be proceeded with. Sedums and Saxifrages may be divided and planted in any place where not too much shaded and where the soil does not become soddened from too much water, and Sempervivums should be inserted in firm soil. Echeveria secunda glauca may have the offsets inserted closely together in boxes or pans. All that is wanted is to firm the soil well around the base of the offsets, and placing the pots outdoors in the full sun. E. retusa strikes freely from cuttings, and E. metallica may be propagated from leaves, but the young leaves only are available. The great bane of Echeverias in winter is damp, but by care in watering and with a light roof they may be wintered without loss. It is not necessary to propagate a great quantity of Mesembryanthemums, Alternantheras, Lobelias, Iresines, or Coleus, yet the needful stock must be raised for propagating in spring. Similar remarks apply to such flowering plants as Verbenas, Petunias, Ageratums, &c.; but Pelargoniums should now be propagated to the full extent for next year's supply, most of the kinds striking readily upon a sunny border provided the soil be well firmed about the base of the cuttings. Cuttings inserted now will be ready for potting at the end of September. We (for want of room to winter the plants in single pots, which is by far the best plan) insert the cuttings in boxes about 3 inches deep, 2 feet long, 13 to 15 inches wide, and place them in the full sun, housing them before frost. Go over the beds frequently for the removal of spent flower trusses and dead or decayed leaves, keeping the lines and divisions well defined by constant pinching. Weeds, too, must be kept from the walks, those and the grass well rolled, the verges regularly cut, and the machine run over the lawn frequently to maintain a neat appearance throughout.

Cuttings of Hollyhocks may now be inserted in gentle heat in a frame, shading them from sun until rooted, also Dahlias of any new varieties. Pansy cuttings strike freely now in cold frames or in borders kept moist and shaded from sun; also save and sow seed of Pansies, Polyanthus, Auriculas, and Anemones. Carnations may yet be layered. Roses may yet be budded; the Tea-scented and China strike freely under handlights on a north border, selecting ripe wood. Seedling biennials or perennials must not be allowed to become drawn in the seed bed, but must be pricked off; those already pricked off and requiring more room may be planted in their flowering quarters, particularly Wallflowers and others required for early bloom. Cut back the rampant growths of Roses so as to throw more vigour in the flowering shoots, removing all decayed blooms, and make all neat not only as regards the plants and beds or borders but the surroundings. Cut away the flower stems of herbaceous plants as they go out of bloom, keeping all about the plants clean and tidy. Evergreens having completed the growth and the wood become firm may safely be transplanted in moist weather, and the work being carefully performed the plants will receive no check but will root freely in the warm soil. Complete the cutting of hedges, screens, &c., without further delay. Holly and Laurels should only have irregularities removed, and never with the shears, which mars their

appearance for a considerable time. Any irregularities in the growth of shrubs may also be removed, giving them a neat appearance for the remainder of the season. Propagation of evergreens from cuttings may now be proceeded with, the wood being firm.

FRUIT HOUSES.

Vines.—Those in the earliest forced house will be casting their leaves and should have all the ventilation practicable, and the border allowed to become as dry as is consistent with the preservation of the roots. The Vines should be pruned at the end of the present or early part of next month at latest, the house thoroughly cleaned, repaired, and if required painted, the Vines being dressed, removing no more than the loose bark, and washing the rods, &c., with a solution of soft soap 8 ozs. to the gallon of water. If there be any scale or mealy bug a wineglassful of paraffin may be added, with flowers of sulphur to bring it to the consistency of cream. Apply to every part, after mixing thoroughly, with a brush. The borders both inside and outside should be cleared of the old mulching material and the loose surface soil, and have a top-dressing of turfy loam with about a fifteenth part of bone dust incorporated. If the border be dry a moderate watering should be given and the house kept as cool as possible.

Vines started late in the spring will need to be excited by sharp-firing, so as to have the fruit well ripened by the middle or end of next month at latest, maintaining a night temperature of 70° to 75° or 80° by day, up to 85° or 90° with sun, this being the period to make up for lost time instead of deferring firing until the Grapes show colour, as they may not do until September is well advanced, prolonging the ripening into October or later. Grapes so ripened do not keep plump or satisfactorily to a late period. The atmospheric moisture, as well as that at the roots, must be kept up in proportion to the condition of the Vines and the temperature maintained, accompanied with free ventilation so as to accelerate the ripening process. Vines in other houses that were started in good time will be well advanced towards ripening, and should have the atmospheric moisture reduced gradually without giving more fire heat than to keep up a circulation of dry warm air, which will be all that is needed to secure well-ripened wood and highly finished fruit. Vines from which the Grapes have been cut must have all laterals closely stopped, and a dry warm atmosphere with abundant ventilation maintained to insure the thorough maturation of the wood. With a view to the preservation of the foliage give a good washing with the garden engine on fine evenings, especially if there be traces of red spider.

Peaches and Nectarines.—If any planting or lifting of trees for early forcing require to be performed soil should now be procured and stacked, which will reduce the turf considerably before it is wanted, and will be in a more suitable condition than if used fresh. Strong turfy loam with a fourth or sixth part of marl, according to the character of the loam, forms an excellent compost, and this without an admixture of dung or other material will grow Peaches of the finest quality. New borders must have efficient drainage, the bottom of the border being concreted if the strata beneath the drainage be unfavourable, or better laid with brick on flat and run with cement, the border being further enclosed with walls so as to confine the roots. It is essential that the drains have a proper fall and outlet, rubble being placed over them 9 to 12 inches thick, and turf grass side downwards upon it. The borders should be 30 inches deep, and be ready for planting by the end of September. Trees of three or four years trained to walls should be chosen, and if lifted carefully they will experience little or no check. The best kinds for early forcing are Early Beatrice, Early Alfred, Hale's Early, Royal George (best of all), Noblesse, Grosse Mignonne, and Stirling Castle, which will give a lengthened succession of fruit. Of Nectarines plant Lord Napier and Elruge. The trees should be planted inside, but with access for the roots to the outside border.

In the earliest-forced house the leaves will soon be off, when loosen the shoots from the trellis, clean the house, seeing to the needful repairs, and painting of the woodwork and trellis. The mulching and loose surface soil should be removed and replaced by fresh loam with a twelfth part of bone dust and a twentieth of wood ashes, affording a moderate watering if the border be dry. Whatever pruning is required should be done so soon as the house is put in order, but if the trees have been properly attended to very little work will require to be performed by the knife, and dress the branches with soft soap, 8 ozs. to the gallon of water; if there is any scale add a wineglassful of spirits of turpentine, with as much tobacco juice as the solution will admit of without curdling, which is about half that of the soap solution. The trees in all but the very latest houses will soon be cleared of the fruit. Thin-out all shoots not required, so as to admit light and air, and if the wood be at all green and sappy turn on the heat, giving all the air practicable night and day. The circulation of warm air will tend materially to ripen the wood and plump the buds. Trees that have ripened their wood may be fully exposed to the weather. See that the borders do not want for water, especially those inside, and syringe the trees well with the engine if there be any traces of red spider.

PLANT HOUSES.

GREENHOUSE.—*Cinerarias* for early flowering shift into the

blooming pots if not already done. Six-inch pots are a useful size for general decorative purposes, but for extra specimens 8-inch pots are not too large. The plants do well in four parts of turfy loam, one part each old cow dung or well-decayed horbed manure, and leaf soil, with a free admixture of sand. They should be grown in frames or pits upon ashes always kept moist, and have shade from fierce sun. In a dry atmosphere they become infested with thrips, which with aphides must be kept under by repeated moderate fumigation, or, what is more certain, dipped in tobacco juice diluted with six times its bulk of water. Pot off later-sown seedlings and offsets or rooted cuttings for spring blooming, placing them in cold frames to be kept close and moist until the plants are established.

Cyclamens will soon be active, and should be potted before they have made many fresh roots. In potting it is only necessary to remove the old soil that comes away freely, and the surface soil, rectifying the drainage: keep the combs about three parts out of the soil, their upper parts being level with the rim of the pots. Pot moderately firm, using good loam with a fourth of well-decayed manure and a similar proportion of leaf soil, providing good drainage. Place the pots on ashes in a cold frame, and water as required, yet avoid overwatering. Seedlings sown this spring will now be in the blooming pots. Do not overpot them—a 4 or 5-inch pot will be sufficiently large, and for older plants 6 or 7-inch pots. Seedlings shifted into the flowering pots early in July will have made good progress, and should have air very liberally, and slight shade only from bright sun.

Primulas sown in spring shift into the flowering pots if not already done, for if longer delayed they will not fill the pots with roots to flower satisfactorily. The soil mentioned for *Cinerarias* will grow them satisfactorily. Keep the plants near the glass, allow them plenty of room, and admit air freely, affording shading to break the fierce rays of the sun. Remove all trusses of bloom until the plants are strong and have filled the pots with roots. Pot-off and shift into larger pots plants from later sowings.

Lachenalis pot, they do well in turfy loam with a little leaf soil, affording a light airy situation near the glass; also *Tropæolum tricolorum*, T. Jarratti, &c., taking care not to break off the growths. They do well in sandy loam with a little leaf soil, covering the tubers an inch or so deep, placing them in a light situation, and securing the growths to trellises as they advance. Few plants are finer than Guernsey and Belladonna Lilies in late September or October. Grown in pots or pans they are very effective, and should have the bulbs entirely covered with soil—good rich loam, and if the pots or pans be surfaced with *Selaginellas* it will materially add to their good appearance. They should be placed near the glass in a cold pit, being kept moist and rather close. Procure the bulbs before they have pushed the scapes more than an inch or two.

Pot a quantity of Roman Hyacinths for early flowering. If for cutting they may be placed about 2 inches apart in pans or boxes, employing turfy loam with a fourth of well-decayed manure. In potting just leave the crowns clear, and place the pots in a cold frame, and cover with ashes or cocoa refuse to the depth of 4 to 6 inches. Paper-white Narcissus and double Roman Narcissus should also be potted without more delay for early bloom, treating similarly to Hyacinths, only they require a little more room. When they have rooted and the growth from the crowns is an inch long place near the glass in a light airy house, having a minimum temperature of 50° to 45° from fire heat.

Pelargoniums cut down, letting the soil become dry before doing so, placing at once in a pit or frame, as they must not become saturated with water, but be kept rather dry until fresh shoots are made. Cuttings may yet be inserted of the thoroughly ripened wood, inserting them around the sides of pots about 1½ inch apart and place them in a cold frame shaded from sun; they will soon root, and may be potted singly in 3-inch pots in turfy yellow loam with a fourth part of leaf soil and a sixth of sand, draining the pots well, wintering near the glass in a light airy house, cool but safe from frost. The earliest-cut-down plants should be turned out of the pots before they have grown too much, or they will receive a check not favourable to the aftergrowth. Young plants that it is desirable to grow on should only have the old loose soil removed, merely shortening any very long roots, but those that are as large as required may have the ball and half or more of the roots cut away. Pot firmly in small pots. Place the plants in a light airy pit or house, sprinkling them overhead every afternoon.

Camellias that require a shift into larger pots and have the buds about the size of peas—not larger, better if a little less in size—may now be potted. Do not give a large shift, as the roots do not require so much space as those of most plants, and be careful in removing the crocks not to injure the roots, merely removing any loose soil and decayed roots. Drain well and pot firmly, using lumpy loam stacked no longer than to effect the death of the grass, it being taken about an inch thick from a pasture with its turf. Water copiously, yet avoiding making the soil sodden. An addition of a third part sandy peat may be added if the plants are young with a little leaf soil, but we employ loam only with the best results.

TRADE CATALOGUES RECEIVED.

James Carter & Co., High Holborn, London.—*Illustrated Catalogue of Bulbs, Plants, Roses, &c.*

Sutton & Sons, Reading.—*Illustrated Catalogue of Bulbs, Plants, and Garden Requisites.*

Louis de Smet, Ledeborg-lez-Gand, Belgium.—*Autumn Supplementary Catalogue of General Decorative Plants.*

TO CORRESPONDENTS.

* * * All correspondence should be directed either to "The Editors" or to "The Publisher." Letters addressed to Mr. Johnson or Dr. Hogg often remain unopened unavoidably. We request that no one will write privately to any of our correspondents, as doing so subjects them to unjustifiable trouble and expense. Correspondents should not mix up on the same sheet questions relating to Gardening and those on Poultry and Bee subjects, and should never send more than two or three questions at once. All articles intended for insertion should be written on one side of the paper only. We cannot reply to questions through the post.

BOOKS (*Aspirant*).—You can obtain them by ordering your bookseller to procure them.

EUCALYPTUS GLOBULUS.—The Gardener, Swanmore Parsonage, Ryde, Isle of Wight, wishes to know where he can obtain seed of this Eucalyptus.

SEEDLING PHLOX (*R. J. W.*).—It is a pretty variety of Drummondii, but not new.

SCARLET-FLOWERED CLIMBER (*K. T.*).—We can only suggest that the plant to which you refer is *Tropæolum speciosum*.

PINK BEDDING GERANIUM (*Manx Cat*).—The variety to which you allude as being so effective in Kensington Gardens is Mrs. Turner. It is quite one of the best of its colour, especially for large beds.

GRAPES SHANKING (*E. F. W.*).—We fear you cannot arrest the shanking of the present crop, but you can arrest the decay of berries that are not shanked by a freer system of ventilation and maintaining a drier atmosphere. The wood and bunch suggest that you keep the vinery too close and moist, and also that the Vines are deficient of surface roots. If before you start the Vines next spring you remove the surface soil from the border, baring the roots and lifting some of them, and cover them with a fresh compost of rich turfy loam, you will induce the emission of surface roots, and shorter-jointed wood and better Grapes will follow. Surface roots will form the more quickly if you can place fermenting material on the surface of your Vine border after you have applied fresh soil.

SOWING APPLE SEEDS (*Pomona*).—Dr. Harvey's statement is quite correct. He does not say that buds from the Crabs recur to the Sweet Apple.

ASTERS (*Mr. Hakeman*).—The plants are evidently well grown, and the blooms are good of their kind. They appear to be intermediate between the quilled and imbricated Aster. Although effective for garden decoration, they are deficient in symmetry and refinement, and do not, we think, possess special merit.

VINES SCORCHED (*Amateur*).—There is nothing seriously the matter with the leaves, they being quite free from insects. The yellow spots are a result of inefficient early ventilation during the late hot weather, accelerated by the vigour of the Vines, which alone is sufficient to account for the discoloration, whilst others in the same house escape.

CLIMBING PLANT UNDER PROJECTING EAVES (*G. H. H.*).—You say that nearly every plant you have tried upon your sunny sheltered west wall, over which the eaves of your house project, becomes covered with insects and filth. The best advice we can give you is to syringe the plants thoroughly once a day during the season of growth, except when they are in bloom. If you cannot do this then plant *Cotoneaster microphylla* or Ivy. Any enthusiastic gardener would highly value such a snug wall in your sunny western county and fine climate. The Pomegranate would no doubt thrive well under such advantages, so would the Myrtle. We hardly need point out the superior advantages of such a position for securing an early supply of tender Tea-scented Roses.

LETTUCES FOR SPRING (*Amateur*).—It is not too late to sow Lettuce seed for raising plants for standing the winter. Sow at once the Black-seeded Bath Cos and Hardy Hammersmith, and any other approved varieties. The other information you require is supplied in "Work for the Week."

GRAPES COLOURING (*D. E. F.*).—You have been wrongly informed. Inside borders must not be kept dry after the Grapes commence colouring, but, on the contrary, if the soil is porous and well drained a good soaking of water will be highly beneficial.

BEDDING IN THE LONDON PARKS (*E. York*).—The flower beds are probably as good now as they will be at any subsequent date. They will be worthy a visit any time from now until the middle of September. Hyde Park is readily reached by omnibus from the Bank, Battersea Park by river from any of the piers, and Victoria Park by rail from Liverpool Street to Cambridge Heath station.

ROMAN HYACINTHS (*W. P. T.*).—These are much smaller than the Dutch Hyacinth and flower earlier. The flowers are pure waxy white, and highly suitable for cutting for bouquets and vase decoration. The bulbs should be potted early in September, placing about five in a 48-sized pot. If strong, each bulb will produce three or four spikes of flowers. They should be potted in rich sandy loam and be buried in ashes until growth takes place, then removing them to a shelf in a light house. They flower from November onwards, and are well worthy of cultivation.

PEARS DISEASED (*B. H. P.*).—We suspect your Pear tree is growing on a

rather poor sandy soil, and is not sufficiently nourished. Dig-in a good dressing of well-rotted dung all round the roots.

MAGGOTS IN PLUMS (*R. T. Crochurst*).—The red grub of the Plum is the larva of a small moth, *Tortrix nigricana*. Köllar says, "Our first endeavour must be to get the Plum-grub from the tree as soon as possible. If we see, for instance, that a Plum begins to ripen before its usual time we should shake the tree to make that Plum fall, and immediately convey it out of the garden. The shaking of the tree must be continued several days, because there may be Plums containing caterpillars that are not sufficiently ripe to fall at the first shaking, though these Plums always appear to ripen much sooner than the others, as the severe wound which the Plum has received brings on a premature ripening. The fallen grub-eaten Plums should all be picked up immediately, because the caterpillar does not remain long in the fruit lying on the ground, as it has in general attained its utmost size before the fruit falls."

NAMES OF FRUITS (*L.R.*).—Irish Peach. (*A Subscriber*).—1, not known; 2, Irish Peach.

NAMES OF PLANTS (*Mrs. Holmes*).—1, *Aconitum Napellus*; 2, *Francoa appendiculata*; 3, *Scrophularia aquatica* fol. varieg.; 4, *Potentilla elatior*; 5, *Geranium lancastriense*; 6, *Sedum oppositifolium*. (*G. L.*).—*Clematis Flammula* or Sweet-scented Clematis. Propagate by layers in September, or by cuttings under a handlight in summer. (*F. T. F.*).—*Spergularia arvensis*, *Cnicus palustris*. (*On Garçon*).—1, *Veratrum nigrum*; 2, *Pentstemon Hartwegii*; 3, *Mentha rotundifolia* foliis variegatis. (*G. M.*).—1, *Pyrethrum Parthenium*; 2, *Senecio*; 3, *Potentilla Rector*; 4, *Teucrium Chamedrys*; 5, *Sedum hybridum*; 6, *Aster laevis*; 7, *Chrysanthemum discoid.* var. (*Jan.*).—1, *Davallia canariensis*; 2, *Araujia racemosa*; 3, *Styrax officinalis*. (*W. M.*).—2, *Hyssopus officinalis*; 2, *Origanum vulgare*; 3, *Thymus vulgaris*. (*J. W. B.*).—1, *Campanula isophylla*; 2, *C. muralis*. (*Somerset*).—1, *Hypericum hircinum*; 2, *Hypericum Androsæmum*; 3, *Solidago serotina*; 4, *Sedum spurium*; 5, *Hyoscyamus niger*; 6, *Chlora perfoliata*. (*Flora*).—*Atriplex hastata*. (*F. S. F.*).—*Chenopodium polyspermum*. (*W. Dickson Hoyle*).—Parsley-leaved Vine called *Cicotat*. (*Dr. Parry Hodges*).—*Bocconia jeddoensis* It is a perennial herbaceous plant.

THE HOME FARM:

POULTRY, PIGEON, AND BEE CHRONICLE.

CULTIVATION OF TRIFOLIUM.

TRIFOLIUM INCARNATUM, or Italian clover, first attracted notice in this country as a flower for borders on account of its deep crimson blossom. It was soon, however, understood to possess valuable properties as a fodder plant, and notably for its early growth, but the cultivation was found at first to be difficult. The farmers were so imperfectly acquainted with the best mode of preparing the land, that a few years after its first introduction it well nigh went out of cultivation altogether. Being one of the first successful growers of Trifolium we continued to grow it through evil report and good report, and an article upon its cultivation contributed by us about thirty years ago assisted in keeping the subject before the public. It has now obtained such a firm hold on the estimation of growers that its growth is general throughout the kingdom, and it is valued as a green fodder crop beyond all others, more particularly from its being not only extremely productive but at the same time most nutritious. We have always remarked that all kinds of stock, whether of sheep, cattle, horses, or swine, are not subject to the scour whilst feeding on it, as they often are whilst eating vetches, rye, &c.

The preparation of the land is of prime importance, and Trifolium differs in most respects from other varieties of clover in requiring the land to be clean and at the same time firm. Ploughing the land, let it be treated ever so well afterwards by harrowing for a fine tilth and rolling to obtain firmness, is found not to answer so well as to select a wheat, oat, or barley eddish, fork out any lumps of couch, and then scarify the surface as shallow as possible—just deep enough to destroy the weeds and obtain sufficient loose mould to bury the seed. Better still is to choose a stubble field after any cereal crop, sow the seed, then drag and harrow to bury it, and lastly to use the chain harrow, and finish off the land with a heavy ring roller, rake off and carry away any rubbish and stubble, then strike and make out the land and water furrows.

In choosing the seed we should decide at what period we require the fodder, as we have now three different sorts at least, which produce a crop at three different periods, instead of formerly. When Trifolium was first grown we then had but one sort, the early sort of a rich crimson colour, whereas we now have a second early sort of a pink-coloured blossom, and the latest of

all is known by its perfect white blossom. We can sometimes obtain a late red variety, but it cannot be so well depended on to give the latest crop as the white. These three sorts may all be sown in the autumn, and will give a capital succession of green fodder from the 1st of May until the 20th of July if sown in certain quantities of each kind. It is, however, now the practice for particular requirements to make a succession of sowings in the spring months of the two earliest varieties, so that the fodder may come for use after the autumn sowings are used. If we sow the seed at any period in the spring and allow about twelve or fourteen weeks for its growth, capital crops can be obtained for green fodder down to the middle of October. The seed may, therefore, be sown at any time between the 1st of March and the 20th of May, and insure a succession of this valuable green fodder from the first week in May until the second week in October. The best time for sowing in the autumn is immediately the corn is cleared, and all three sorts should be sown at the same time. Although the late white sort does not come for use until last, yet it requires to be sown early, as it grows slowly and is a more delicate and tender plant than the other varieties. It is necessary, therefore, to have the plant strong and well established before the severe weather of winter begins. The chief advantage of early sowing is that we are more likely to avoid the depredations of the little white slug, which is almost the only insect enemy to be feared, and these seldom affect the plant much until the autumn rains and long nights commence. So important is this crop in our own estimation that we recollect some twenty years ago, when the first sowing of 20 lbs. of seed per acre failed, we then sowed 25 lbs. of seed per acre, and that was carried away by the slug also. We then proceeded to sow 30 lbs. per acre as late as the second week of November; it came up very well, and the white slug could not work in consequence of the white frosts. But to show how hardy this plant is, although the seed was only just come up when the frosts began, yet it resisted the weather of winter and proved a valuable crop, although not quite so early as usual.

The soil best adapted for the growth of Trifolium is a sandy or rather strong loam. We have, however, grown it upon nearly all soils, including light gravelly land, and if the land is in good condition it will give a heavy produce; and as the ground is always mellow and kind for root crops after the Trifolium is removed, it must be considered the best preparatory crop for roots of all the crops grown for soiling, cattle, &c. For feeding sheep upon the land this crop is first-rate, but it should be folded-off when young, otherwise the stock tread it down and do not make clean work. When this is likely to be the case we prefer to cut the crop with the scythe and put it into the hay racks, or cages as they are called, for the sheep. What they leave can then be removed, and without delay to the ploughing and sowing of the ground with root crops. We have grown splendid cabbages after Trifolium, our plan being to lay out the manure and rake it into every third furrow at the time of ploughing, and plant the cabbage on the furrow immediately over the dung. To save time we have sometimes strewed guano or other hand manures into the furrow at the time of ploughing.

Unless Trifolium is saved for seed it should be used whilst the stalks and haulm are soft and succulent, as the ripening process begins early and rapidly. When once the stalk becomes hard and wiry it possesses but little nourishment for cattle-feeding. If it is required for hay it must be cut very early, and just as the blossom commences to make its appearance. Under any circumstances it makes but poor hay compared with the clovers, and this is rather odd, considering its extraordinary feeding value in the green state. It must be noted also that Trifolium for hay is injured much more by a shower of rain than the clovers. Trifolium is often a paying crop if saved for seed, particularly upon light gravelly soils, which give but a poor return in the growth of cereals, and we have known, even when the seed has not been worth over 4d. per lb., the crop has proved much more valuable than either wheat or barley upon the same kind of soil.

Notwithstanding this, such soils will produce good crops of common turnips if fairly tilled and manured after the Trifolium crop is taken for seed. We have likewise noticed that soils in our own occupation, upon which we had repeatedly failed to obtain a plant of broad clover, have, when the Trifolium has been fed with sheep followed by roots and barley, produced a regular plant and fine crop of broad clover; and it is in fact the only remedy we know of in cropping for land which is termed "clover sick." It sometimes occurs when Trifolium is sown in August under favourable circumstances that it becomes very luxuriant, and likely to become laid and twisted with the autumn rains. In such case we have seen it fed by forward ewes and lambs in the months of October and November, but not penned in a close fold, which would damage the crop. When sheep are only allowed to take off a little of the strongest plants it protects it from damage, and, although rather later, it will prove a good crop in the spring.

The feeding value of Trifolium is different when used for certain kinds of animals. For instance, when given to farm horses whilst in flower, it is so good and sustaining to them in their work upon the land that we have known them refuse their usual allowance of oats, and have frequently found a portion of their corn and chaff food in the mangers uneaten when they have had access to a full bait of the Trifolium. Fattening cattle eat it well at the racks, and we have found them lay on flesh faster when eating Trifolium than when consuming clover, Italian rye grass, or any other green fodder. We have not, however, found that it is best for milch cows, as in some instances the cows' milk would decrease as compared with the yield under clover or grass feeding. It is equally good for young heifers or steers when used as supplementary food whilst grazing on pastures, but more particularly we have found it beneficial when given to our young animals in the boxes whilst feeding for "baby beef." It is equally good for store pigs and breeding sows. We, therefore, conclude that the great value of the produce consists in its power of sustaining working horses or forwarding the condition of cattle intended for the shambles.

WORK ON THE HOME FARM.

Horse Labour is now principally required in carting the cereal produce to stack or barn, also the pulse crop, such as beans, peas, or vetches as they come ready for harvest. We will here remark that we have noticed some extraordinary crops of mixed pulse, such as beans and winter vetches, also beans and the small late maple peas grown in admixture. These are nearly sure to answer well grown as a double crop, because they hardly ever both blight in the same season. It is for that reason that they are grown in admixture, and are certainly a much safer crop than when grown separately. When the season happens to be favourable for both it is quite astonishing the quantity of pulse which is sometimes produced, for the beans not only produce in great abundance, but they support either peas or vetches, so that they flower and pod with great luxuriance.

At intervals, when the horses are not employed in harvest carting, they should be engaged in ploughing for stubble turnips, and when these are sown the horse-power upon the home farm should be directed to autumn cultivation, and as much of this as possible should be done before the laying out dung, &c., in preparation for the wheat crop commences. The chances are that after the preparation for the wheat sowing commences there will be no opportunity for further cultivation of the land intended for roots next year, except that the portion which had been surface-tilled before the autumn rains set in may then be deeply ploughed or ridged up for the reception of the various changes of weather during the winter months, all of which contribute to fertilise the land and reduce it to a state fitting it for the growth of root crops in perfection.

The odd horse will still be engaged in horse-hoeing the latest-sown Swedes and common turnips, and during the harvest period the work of carting green fodder for the horses and cattle will fill up the time of one horse and man. We find, too, that the borders which afforded gross crops of grass, hogweed, and cow parsley, &c., up to midsummer have been fit to cut the second time for several weeks past, and give at the present time a lot of good succulent green fodder, which is eaten readily by young cattle at the stalls and by dairy cows. This is especially relished by the breeding sows and store pigs feeding on for early quarter pork, the latter getting an allowance of Indian corn and barley meal. The green food gives the animals a good appetite for the meal, &c., and thus keeps them growing as well as fattening. Under this way of feeding the manure made is valuable, especially when the sties are bottomed with good loamy earth, and littered with straw as cleanliness requires. It is, however, found when the grass, &c., from field borders are given to pigs, the whole is not always consumed, the remainder going far towards economising straw required for litter.

Hand Labour.—The hand labour, for which the demand during harvest is always great, will now consist of tying the corn behind the reaping machine. Upon some small home farms, however, hand-reaping, mowing, and faggotting are still a necessity unless a reaping machine can be hired for the occasion. After heavy storms of wind and rain hands will often be required to set up

the sheaves which have been blown down, and in setting them up into shock again in exposed situations we prefer to set them up in round shocks, which are not so easily blown down. The thatchers, too, will now be busy, for they will be required to thatch not only the corn ricks but the ricks of second cutting of clover hay. It is desirable, even after the ricks of corn have taken rain, to thatch them immediately, for we have always found it better to thatch in the damp than expose the ricks to further risk: we find any damp under the thatch will always dry out.

When the men cannot tie the corn they should not be allowed to cut it but put to other work, such as drawing straw in readiness for the thatchers during the intervals when corn cannot be cut. The hoeing or second hoeing of Swedes or turnips may be done, as work of this kind will not wait, and cannot be put off indefinitely without serious damage to the root crops. At this time of the year the great fairs for the sale of sheep are held, and the requirements of the home farm must be attended to, and such breeds of sheep purchased as are adapted to the soil and climate and the nature of the food to be consumed. The corn stubbles and pastures will be generally full of good keeping for sheep during the coming autumn, and the sheep now being offered for sale in both the midland and southern counties, either of ewes or lambs, are in prime condition, and we have not seen them better or freer from lameness and disease than at present for many years. It is a good plan, therefore, now to purchase the ewes for breeding, because when they are in good condition they are more likely to offer to the ram earlier and with more regularity, and this matter will be found of great importance at the lambing time.

EARLY CHICKEN SHOWS.

We have always consistently advocated poultry showing merely as a means to an end—viz., the ultimate improvement of our breeds of poultry, which is only likely to be attained by the diffusion of a more thorough interest in and knowledge of the subject. As a mere objectless pastime, for which birds are sent about from show to show till they are ruined, we have always deprecated it; consequently we have never been among those who greatly patronise many early chicken shows, at which immature cockerels and pullets necessarily appear. These early shows, however, are by no means useless, and contribute considerably to the amusement of many fanciers, who could hardly be expected to give them time and attention to the far-off end of leaving a good strain of fowls behind them, without some diversions meanwhile from comparison of their stock with that of their neighbours and the merited rewards of successful production. We will, therefore, say a few words about the advantages of these shows and about the system of preparing birds for them. Early maturity is greatly to be desired in our young poultry both for table use and for the production of a good supply of late summer and autumn eggs. As a test, therefore, of who can rear the earliest spring chickens, so valuable both for home use and sale, and the most matronly pullets to provide eggs, the prize list of an early show is of considerable value.

The price of really good spring chickens in London and other towns has become quite exorbitant; it is no little credit, then, to a breeder to be able to supply his own table or the market with delicious chickens when most of the world are obliged either to go without them altogether or to eat meagre apologies for them in the shape of dwarfed autumn birds, or veritable old cocks and hens. Eggs, too, become yearly dearer. Even in the country we are now asked as a favour for our superfluous eggs at 1s. 6d. a dozen in the summer months to be sold again at a profit! Early pullets which will produce them in abundance from July into the late autumn are obviously very valuable. Chicken shows, then, at which none but really early birds have a chance of winning, must give a stimulus to the breeding of such stock. Some breeders, it may always be observed, are more successful at the early, others at the later shows. This may depend upon their system, or upon the situation and climate of their yards. We have of late ceased ourselves to attempt early exhibitions from living in a high position much exposed to spring winds, where the stock birds seldom lay in winter, and where the growth of early chickens is so much checked that they never come to large size. Others, again, who have great success in rearing chickens actually in the winter fall entirely to keep later birds growing through the autumn. Some few who are fortunate enough to have great space or variety of ground are equally successful at the early and late shows.

We have in previous numbers written about the management of early chickens in their infancy; if they have duly developed the best of them should by this time be fit for the show pen. As for the later shows, the great object is to keep them growing and chicken-like as long as possible; so of course for the early birds it is to bring them into full plumage with rosy combs. For this purpose the cockerels and pullets to be shown together are generally allowed to run together for some while before the exhibition. If they must be so shown this is better than putting them together for the first time in the show pen, from which a skirmish is sure to ensue. Where, however, they are shown separately we should in the case of the larger varieties, especially Dorkings, prefer

keeping them apart, and if the cockerels require some forcing give them a little Spratt's food in their ordinary meal. The plan to be pursued at the Hemel Hempstead Show strikes us as a good one—viz., for a cockerel and pullet to compete as a pair, but in separate pens. In the case of the smaller breeds—Silkies, Hamburgs, and Bantams—the sexes of those to be shown early should not be separated, and all may with advantage have some stimulating food. We may give a hint, too, that in the case of varieties where sickles are a necessity care should be taken that the destined prizewinner has so much as possible his own way. We have observed among our own Hamburgs and Bantams that a cockerel which is "cock of the walk" always develops his sickles rapidly; but if the cockerel be kept under by an old bird they are very slow in growing this appendage of maturity.

Summer shows are generally short affairs and held under tents without the unnatural and exciting adjuncts of crowds of evening visitors and blazing jets of gas, hence chickens may be sent to several shows without material injury. It must, however, be remembered that birds forced on for them seldom prove fine specimens in the end, and are usually quite out of condition for the later shows. We have known some remarkable exceptions to these rules, usually when the chickens have gone suddenly into a moult like that of old birds, developed much during it, and have then come out in handsome fresh plumage. As a rule they continue small (though, unfortunately, this does not follow in the case of Bantams), and are useful, as we have said, rather for present exigencies than for future reproduction of their kind.—C.

WINCHESTER POULTRY SHOW.

THE first poultry Show, and the first south of England chicken Show of the season, was held at Winchester on the 15th inst. and following days. We were informed that two months ago the Show was not thought of. A few gentlemen conceived the idea that a poultry show would be appreciated in the town invited Mr. T. C. Burnell to join the Committee, and with his advice and assistance an admirable collection was produced. Twenty classes of poultry obtained 213 entries, and twelve of Pigeons 130.

Dorkings.—First a substantial bird, but rather oval in the back and queer on the feet; second smaller, and crooked in the legs; third a good Silver. *Pullets*.—First a fine well-grown bird, a little sooty in feet. *Cochins*.—Cockerels, fifteen entries. First a fine Partridge, second a better Buff but not so forward, third a Partridge. Pen 39, unnoticed, a beautiful White entered as eighteen weeks—much too young for the company. We thought him the most promising in the class. *Pullets* a large class (thirty entries). First a nicely pencilled Partridge, rather deficient in leg feather; second a well-shaped sound Buff, same owner, we thought should have been first; third a large Buff, but tinged in hackle. *Brahmas*.—Cockerel.—First a good Light, second and third moderate Darks. Pen 81, another Light, we thought should have superseded the Darks. Pen 78, a Dark, was in colour and other respects the best in the class, but he showed unmistakable signs of a twisted hackle. *Pullets*.—First a Dark of sound ground colour but deficient in markings. We much preferred the second, a well-developed Light of excellent shape and beautiful markings. Pen 83 (Stevens) extra prize, we also liked better than the winner. *Game*.—Cockerel.—First a promising Black Red; second also a Black Red with nice style, but not so neat in head as the winner. *Pullets*.—A dashing-looking Pile first, second a small but capital-coloured Duckwing, a little loose in the tail. *Hamburgs*.—Only nine entries in the two classes; the winning pullet, a Golden, was well pencilled. *French*.—Capital classes. *Cockerels*.—First, a fine Crève, but we thought him a little up in the back; second a well-marked Houdan. *Pullets*.—The winner a splendid Crève, we thought her the pick of the Show; second a well-marked Houdan. *Bantams* were a moderate lot. *Any other variety*.—A rather forward Spanish cockerel was first, second Polish, third a good Andalusian. A pretty pullet shown by the same exhibitor was second in the following class.

Pigeons, considering the period of the year, were better than we anticipated. Carriers nine entries. The winner we did not like; he was larger in beak wattle than the others but uneven round the eye, thick in the neck, and coarse in style; second a Black; third a Dun, we thought birds of a much higher class. Pouters and Fantails followed. Good classes. *Dragoons*.—The first, a young bird, was rather down in beak, and for this reason we much preferred the second (same owner), a very old winner and still in good condition. *Any variety Dragoon*.—A capital class, a Chequer was first. *Jacobins*.—First and second Yellows, third a good coloured Red. *Owls*.—First and second (Barnes). The winner has been noticed by us on former occasions. *Any other variety*.—First a Barb, second a Magpie. An extra prize was given to an excellent white Barb that justly attracted the attention of the Judge. No prize list was forwarded to us.

VARIETIES.

AT a recent meeting of the Council of the Royal Agricultural Society of Ireland, Major Borrowes called attention to a new

turnip-crop pest—a species of small green worm or caterpillar, which, within the previous forty-eight hours, had covered a space of twelve acres of turnips on his estate in the County Kildare. Such a thing has not occurred there for twenty-five years. The worm speedily ravaged all the leaves except the centre one, and showed wonderful powers of getting over the ground.

—A LINCOLNSHIRE correspondent informs us that harvest operations have been seriously impeded in that county by heavy and protracted rains. Since August 2nd 5.68 inches of rain have fallen, and since cutting commenced 6.60 inches have been registered. Much wheat has grown green in the stooks, but the weather during the present week has been more favourable, and progress has been made in securing the crops.

—A REVOLUTION is likely to be wrought in the harvest field by the new combined reapers and binders. At the recent trial at Bristol, the gold medal was awarded to McCormick's machine, entered by Waite, Burnell, Huggins, & Co. The machine cut and tied half an acre of greenish oats in twenty-four minutes without a stoppage of any kind, and it finished 1 acre and 26 perches of wheat in fifty minutes, including two stoppages, once snapping the wire. The special merit of the work, says the *Mark Lane Express*, was in its perfect collection of all the corn, scarcely an ear being dropped; thus absolutely the whole of the crop is bound in the sheaves, leaving nothing at all to be raked up, and perhaps not more than a handful per acre for gleaners. About 2½ lbs. of No. 20 gauge annealed wire is used per acre at a cost of 1s. 3d. to 1s. 7d., and the saving in corn from the clean collection would seem far more than enough to pay for this, considering that the old bands are alleged to be saleable at about half price, and the labour of five or six men in manual tying is dispensed with.

—TURF IN ORCHARDS.—An opinion is very generally entertained that turf in orchards is not only not injurious to fruit trees, but is actually an advantage, as forming a covering which prevents the too rapid drying of the soil. Both of these views, says a Berlin paper, are erroneous. As regards the first, it has been actually proved that turfed ground gives out far more moisture than unturfed soil. Practical experiments have shown that during five months in the summer a morgen of turf land gives off, on the average, 800 cubic feet of water a day; unturfed ground, though dry on its surface, is not able to withdraw so much moisture from the subsoil; the evaporation which goes on through the leaves of the grass is far greater.

—A FLOATING BEE HIVE.—Our American cousins have hit upon another novelty, which we find thus referred to in a New York contemporary:—"A floating bee house has been constructed by Mr. Perrine, a Chicago honey dealer, large enough to accommodate two thousand hives, which he is having towed up the Mississippi river from Louisiana to Minnesota, keeping pace with the blossoming of the flowers, and thus stimulating the honey-making ability of his bees. Returning he will stop about two months somewhere about St. Louis, and will reach Louisiana in October. He wants to take advantage of the autumnal flowers at each point. The plan of moving the bees to get the benefit of flowers has been tried in a small way in some parts of Europe."—(*Colonies and India*.)

—MILK AND TYPHOID.—The medical officer of Bristol has traced the typhoid fever outbreak there to a dairy farm. The supply of milk to retailers has been stopped, and every precaution taken. No deaths have occurred, but the area of the outbreak is extending.

POSITION OF SUPERS.

WE all concur with the writer of the reply to "F. J." as to the importance of the correct placing of supers and the principles which regulate being well understood; but he is very much out of order in stating that "it is in harmony with the laws of Nature" the empty being placed next the stock hive and underneath the filling one, and that the contrary practice of those who employ Stewarton hives "has not given us good reasons, or perhaps any reasons at all, placing the empty super above the full ones." The principles which regulate the practice were fully explained in these columns years ago.

It is said that Nature abhors a vacuum, and so does the bee. In the early spring months the population is at the minimum, and the hive if properly constructed should then be small for the better concentration of the heat; with the rise of the temperature and increase of population it is enlarged by means of nadirs placed underneath, it being well known that the brood combs are extended in a downward direction. Now suppose we give a couple such nadirs at once, we do not find the workers descend to occupy the lowest, leaving the nearest empty; they proceed with too much regularity for that. In like manner with the commencement of the honeyflow: supers are set on above and the bees ascend to take possession of the nearest first, and gradually extend themselves upwards proportionately to the population of their storage wants. In short it is ever the anxious endeavour of bees

whether it be broodcomb downwards or honeycomb upwards, to extend them continuously; there are no broken links in the chain of their works, the fresh ones being always added to either end. Even the most unlettered skepist could not fail to note, on removing the cover of the objectionable central hole and setting on a glass, the great caution and care with which the bees extend the frontiers of their waxen kingdom by actually at much trouble building a comb upwards from its base till it can be attached to the top. When they have thus, as it were, hoisted their flag and taken possession comb-building goes on briskly downwards from the top in the usual manner.

When I read the reply to the query referred to I went out to my apiary and removed the super coverings from my best octagon colony, which in addition to the usual breeding space had six honey boxes upon it in different stages of progress. The lowest, or one next the stock hive, was, with the exception of a few cells, sealed out. The second from the stock was about filled with honey; sealing commenced. Third, fully combed and about half filled. Fourth, combed with but thinnish combs, not fully extended. Fifth and sixth, crammed with bees suspended in roped festoons from roof and wax guides. Such was the regular and beautiful gradation with which I found the work progress. The two lowest have since been completed and removed, empties taking their place on the top. Supposing a break of weather to take place, so arranged the bees would have to abandon; but the outposts, falling back on the most valuable part of the store wisely placed, as the supplies always should, nearer the centre. We have known of such a break follow; and a novice who had adopted the plan recommended to "F. J." chagrined to find the bees had carried the contents of the all-but-completed super placed on the top of empty down into the stock hive, evidently impressed with the idea so valuable a part of the commissariat ought not to be left without the lines.

Your excellent contributor Mr. Briscoe has already ably pointed out the risk of ruin from brood, to which the combing super next the stock hive is placed, from incursions of the queen; and his remarks apply with equal force to the ingenious adapter plan of Mr. Fox introduced to the notice of your readers many years ago. By that plan the bee is left no choice. Her most strenuous endeavours to connect her works are frustrated by a super being placed higher and yet higher, on the same principle as the owner of a dog may by raising a bit of meat tempt the animal to spring up and up. It would surely be absurd to say that either feat was "in harmony with the laws of Nature?" To the enlightened apiarian the day of monster supers, as of big straw skeps, is over; profitable bee-keeping consists in adopting the hive and system of bee management by which the greatest weight of comparatively small and completed, most marketable supers can be obtained.—A RENFREWSHIRE BEE-KEEPER.

HARVEST FROM FIRST-CROSS ITALIANS IN STEWARTON HIVES.

REFERRING to the harvest alluded to in last week's Journal my clerical friend informs me that he has now removed all his supers, the actual net weight harvested being 445 lbs. against 430 lbs., his previous estimate of the probable result, at the same time adding, "My harvest hive gave me 92½ lbs., and my next best 88 lbs. of super honey."

For the benefit of the uninitiated it is necessary to explain that the above is only a portion of what each colony severally and altogether gleaned, and irrespective of the mass of honey stored in the three body boxes constituting a stock, which, owing to the peculiarity of the season, I find in all cases this year to be unprecedentedly large.

The last bad barren season was succeeded by a spring so cold and backward that breeding was retarded, in too many instances entirely suspended. It was not till midsummer that we were favoured with really warm honey-secreting weather, which found stocks short of workers to take possession of the accustomed number of supers; and as the most rapid mode of securing the abounding nectar the honey gatherers poured it into the vacant brood cells and there sealed it over, as a sequence lessening the breeding of young bees in that department, and by so keeping the colonies short-handed still further restricted the production of super honey.—A RENFREWSHIRE BEE-KEEPER.

OUR LETTER BOX.

MONGREL CHICKENS (*An Eastern*).—We advise you not to adopt legal proceedings. As long since as 1854 a cause was tried in the Great Yarmouth County Court, and the conclusion was that no one could swear how many generations before the cross had occurred.

AN OLD HIVE NADIRED (*G. C.*).—After taking three supers well filled from your stock hive you drove the bees into an empty one, but on discovering that it was pretty full of brood you put it on the top of the warm hive, and the question with you is whether to let the bees in the top (old) hive or drive them into the nadir or new hive. The bees did well in the old one this year, and as its combs are but fifteen months old we advise you to let them remain. Let the bees have 8 or 10 lbs. of sugar as quickly as possible, then remove the bottom hive, and cover all up for another year.

WHEN SHOULD HIVES BE OBTAINED? (*R. F. R.*).—In country places autumn is the best time to buy bees, for then they are easily obtained. At the time of taking honey most bee-keepers would rather sell their hives for stocks than put them down for honey. But from professional apiarians hives may be bought at any season, and of course there would be less risk of loss in waiting till winter is over before you begin bee-keeping. Mr. Cheshire's hive is a good bar-frame one, but rather too costly for general use or for profit. The Stewarton hive is in many respects preferable to a common bar-frame one, as it possesses greater facilities and capabilities for work and progress. To either bar-frame or Stewarton hives Mr. Pettigrew prefers large straw hives, which are three-fourths less in price, more easily managed, and he finds them better every way.

BARLEYSUGAR AND CROWN BOARDS (*Beevar*).—We do not use barley-sugar in feeding bees, nor do we approve of using it. Doubtless it is made by boiling sugar and rolling it into sticks before it cools. The exact process we are not able to describe, but sugar and water given in liquid form is better and more natural food than sugar in any solid state. The crown boards of frame hives should touch or nearly touch the tops of the frames. When a space is left between them the bees are apt to fill it up with combs, and thus cement them together.

COW FOR A SMALL PLACE (*P. C.*).—There is no cow to suit a small establishment like the Kerry breed. They are small, hardy, and capital milkers, and they will browse on any rough pasture.

INSURING (*B.*).—Apply to the Royal Farmers' Insurance Company, 3, Norfolk Street, Strand, London.

METEOROLOGICAL OBSERVATIONS.

REMARKS.

- 14th.—Fine day, but very windy, slight shower in morning; afternoon very bright, occasional clouds.
15th.—Bright morning; dull in early part of afternoon, but bright again afterwards; fair evening.
16th.—Heavy rain 10 A.M., then an interval of bright sunshine, and heavy rain again between 1 and 2 P.M.; thunder at 1.50; it brightened up again about 4 P.M., and the evening was fine.
17th.—Fine day on the whole, though cloudy and overcast at times.
18th.—Fine day throughout.
19th.—Slight haze in morning, a little cloudy in the afternoon, but on the whole a bright fine day; very slight shower in evening.
20th.—Very hazy and at times dull, but altogether a fair day; much cooler. The weather has been cooler during the week although there has been a good deal of bright sun, consequently all the thermometric values are below those of last week with the exception of the solar radiation temperature. The mean of the barometer readings is also rather lower than last week.—G. J. SYMONS.

COVENT GARDEN MARKET.—AUGUST 21.

TRADE has been quiet, and prices remain much the same, with the exception of Plums, which have experienced a considerable fall. Large quantities of Grapes from the Channel Islands are still arriving, reducing the value of all classes of homegrown fruit. Kent Cobs and Filberts are flat.

From observations taken near London during forty-three years, the average day temperature of the week is 70.9°; and its night temperature 49.5°.

HINTS ON LANDSCAPE GARDENING.—No. 7.

TREE PLANTING.

EMBELLISHMENT, privacy, and shelter are our guiding stars in planting trees and shrubs near or in sight of a house; all are important, but the first is most so from the fact that we are bound to aim at making the whole of the planting ornamental—in the present in some degree, and fully so in the future. Here is a difficulty confronting us at the outset; for how can we expect each tree to grow into beauty and to develop its full perfection of size and form if during the first two or three decades of its existence it form one of a crowd? Well, the truth is we do not expect perfection of form in every tree, but we do want size and vigour, and therefore the planter's work must be followed by much subsequent care in thinning and effecting a gradual clearance of the space intervening between the permanent occupants, so that the spreading branches may constantly be exposed to the full play of light and air. Let this be clearly understood, for trees are often not only planted too thickly, but are still more frequently neglected year after year till they are ruined. Due attention must also be given to the situation, soil, and climate, all of which are important matters, exercising much influence upon the growth and health of trees. In a poor shallow soil we must plant shallow-rooting trees, such as the Beech, Silver Fir, Birch, and Holly. In a deep, rich, or heavy soil, on the contrary, we take the Oak, Elm, Plane, Tulip Tree, Lime (which also answers tolerably well in a thin soil), Horse Chestnut, Ash, Spanish Chestnut, Poplar, and most other trees of lofty and rapid growth. I may here usefully note that Spanish Chestnut also answers admirably in a thin silicious soil, proving superior to everything else as underwood for producing hop poles and fence rails. This tree, like many others, will make a free growth in a variety of soils, growing with almost uniform rapidity for the first twenty years of its existence, and then gradually becoming comparatively stunted and slow in growth very much in proportion to the thin or sterile condition of the soil. An appreciable annual growth is made, however, and in due course they become trees, not large and stately specimens, but yet sufficiently large to form imposing clumps and masses.

A clear understanding of the adaptability of timber trees for different soils and situations is of much importance. An Oak assumes magnificent proportions and becomes a veritable monarch of the forest in a deep rich loam; in point of fact it is only in such soils that it attains its full development, yet in thin soil and on elevated positions it will grow 50 feet high, and affords some shelter in a mass. Much more valuable, however, for both purposes are the Larch and Scotch Fir. I have seen the Larch growing in the deep alluvial soil of a fertile valley considerably upwards of 100 feet in height, and have also measured trees growing upon a slope some 600 feet above the level of the sea, in soil of only medium fertility, that were upwards of 60 feet high. In the deep loams of Kent the Beech grows

to an immense size, and it is also the finest of all deciduous trees, growing in the poor thin soil overlying beds of iron-stone, gravel, and sandstone, upon the forest ridge in mid-Sussex. *Pinus insignis*, *P. austriaca*, *Cedrus atlantica*, *C. Deodara*, *Abies canadensis*, *A. Albertiana*, *A. Douglasii*, *Pinus excelsa*, *Picea Nordmanniana*, *P. Pinsapo*, *Sycamore*, *Acacia*, wild Cherry, the Tulip Tree, Horse Chestnut, Lime, Silver Fir, Scotch Fir, and Larch also answer well in this thin soil, the Silver Fir (*Picea pectinata*), being especially remarkable for its free robust growth. It attains an altitude of upwards of 100 feet, towering aloft above all other trees upon the crest of a slope fully exposed to violent gales of wind from the south-west, forming a bold clump of great beauty, singularly elegant and distinct in appearance. Seen from a distance the tapering symmetrical forms have a sprightly air that is very attractive and which blends well with the Larch, to which it imparts relief in summer and a no less agreeable warmth of tone in winter.

From the limited use of the Silver Fir amongst forest trees it would appear that its full value is not much known; when it is it will probably supersede the Scotch Fir for purposes of shelter, or be mingled with it and help to break up the long monotonous belts and heavy funebrious masses of it which are now so common. Apart from the question of mere appearance its value for timber is superior to the Scotch Fir; it grows to a much larger size in both deep and shallow soils, answers as well in a heavy clay as in a light sand, and has only one weak point, which is that when planted low down in a valley the leading shoots of young trees sometimes suffer from late spring frost, just like that other valuable Conifer, *Pinus insignis*.

In planting for shelter avoid straight lines. The numerous belts of Larch and Scotch Fir planted in all parts of the country some sixty years ago are just so many blots upon the landscape which it is impossible to ignore. Heavy, stiff, and formal in themselves, they rob the most tasteful enclosure of its beauty and are offensive to the eye from every point of view; and yet I like the trees, for individually they possess much beauty, and few trees may be used with more telling effect even for shelter. Instead of planting half a dozen rows along the top of a hill in the old formal style of a belt, throw them all together in a bold central mass upon the top, and let it spread in picturesque irregularity a little way down the face of the slope. Proceed onwards and downwards with deciduous trees, masses of Beech, Oak, Sycamore, Lime, Horse Chestnut, Spanish Chestnut, Hornbeam, Birch, Pseud-Acacia, selecting such of these as appear suitable for the soil, and blending with them the rich lively green *Pinus insignis* singly and in clumps, also Silver Firs, and the light silvery-hued *Pinus excelsa*, and for autumnal effects Tulip Trees, wild Cherry, Scarlet Maple, and Scarlet Oak. An occasional Purple Beech also tells well from spring till autumn. Enrich the lower portion and foot of the slope with the common Ash and its handsome Walnut-leaved variety *Fraxinus juglandifolia*, the Fern-leaved Beech, the Mountain Ash, a few Birch mingled with *Pavias*, Willows, Robinias, Hawthorns, Holly, and *Mespilus*, also introducing a few clustered Scotch Firs here and near the sides.

At any point along the foot of a slope of a valley which it is desirable to close for shelter or to exclude some unpleasant object, turn any suitable portion where the soil is good to account by planting Oriental Planes and the Black Poplar (*Populus nigra*), both fast-growing trees, which must be planted singly or in bold clumps, which when well placed are very telling; but I do not like to see this Poplar among other trees, for it soon assumes such gigantic proportions as to dwarf every other tree near it. No tree is more profitable for timber in a tolerably deep soil, and for certain purposes it commands a good price.

Bold hillsides planted entirely with Larch, Spruce, and Scotch Fir are a common sight, but such a style of planting could only be admissible when profit was the sole consideration. Deciduous trees in variety must always find favour in the eyes of an artist or person of cultivated taste; and in planting for effect we give due weight to the freshness of new spring foliage, the beauty of bursting bud and opening flower, the glorious autumnal tints, the play of light and shadow among the various forms of foliage, as well as the warmth and beauty of evergreen Conifers in winter, when the bare branches of deciduous growth would if seen alone present a forlorn aspect quite the reverse of ornamental.—EDWARD LUCKHURST.

FAILURES IN ROSE GROWING AND SHOWING.

SOME years since a writer in the Journal complained that so many people wrote of their successes, but none of their failures. I endeavoured at the time to supply the omission, and detailed my failure in fruit cultivation. I can now speak with feeling of another failure which pricks me to the very quick—a failure in growing my own particular flower, the idol of my life, and the subject of my labour and thought for ten years.

There is an old Latin proverb which when translated says, "Let not the cobbler go beyond his last." If he does I presume he only meets with failure; but I have stuck to my last, and the harder I have kept to it and the longer I have practised my trade the worse craftsman have I become. This year my Roses have done so very badly that neither with Teas or Hybrid Perpetuals have I secured one first prize. I only showed at the Crystal Palace, Hereford, and South Kensington; but seconds and thirds were the utmost I got, and except at a little local show I have never seen a first-prize card on my stand.

What is the reason of my want of success? In the first place the competition now at first-class shows is enormous. It is true it was always great, and that I have secured first prize for forty-eight varieties at the Crystal Palace in former years; but still I think it is greater than it used to be. If Mr. Baker is in his usual form he is almost invincible. He has proved this on many occasions, and this year he is again *facile princeps* the king of the amateurs. But now we have a giant from the heavy soil of Hereford who has only shown for a few years. If Mr. Baker is Gog, Mr. Jowitt is Magog.

It is almost a certainty that these two are first and second at any show; then comes Canon Hole, who once was monarch of all he surveyed. He must be third at least on all occasions, and after these great leaders of the fight come the Rev. E. N. Pochin, John Hollingworth, and several more. All have good soils, all have right trains, and all have burning enthusiasm in the cultivation of the queen of flowers. I certainly possess the last qualification, but I am destitute of everything else.

As to soil, I do think my soil is the poorest, most heart-breaking stuff ever seen. A bantam cock when airing himself among my Manettis amuses himself with pulling them up with his spurs. We scarcely dare put a hoe among the Roses for fear of pulling them up. The ground cracks in dry weather, and do what we will with moving the soil we cannot keep it from cracking. The manure we put on runs away through the flints and does hardly any good, and we are overrun with rabbits. "I think," said one of my farmers, "I shall have to leave this parish. I want some land that will hold some dressing; besides, my teeth are getting worn out, so I must go." "Teeth! What has the land to do with your teeth?" I ask. "Why, sir, I shall starve to death, for I shall not be able to pick the bones of the rabbits."

Think what it must be to have to keep a man tread, tread, treading all day long to induce the Rose roots to lay hold of the soil; think what my soil must be when I have to place both feet on the roots when I cut a bloom for fear the knife should not cut the bloom but pull up the whole plant. This has often occurred with me.

Then as to trains. There is no train on our miserable line (the sleepy London and South-Western) which leaves Exeter later than five o'clock. Think of that for a great trunk line running from London to Plymouth, and not to have a later train than one leaving Plymouth at two and Exeter at five. Consequently I have to cut my blooms fifteen hours before Mr. Baker, who travels by the Great Western mail; and Canon Hole can cut even later.

So to sum up, I have no soil to grow Roses in worthy of the name; I cannot get any growth, so that my blooms have neither substance nor strength to bear a long journey; and to crown all I have to cut them thirty hours before they see the judge.

"But when you used to be first how did you manage it?" someone may ask. "Had you not the same difficulties to contend with? Why, if you once did it, cannot you do it again?"

This is a very fair question, and one perhaps difficult to answer. The only satisfactory reason I can give is this: When first I came here I saw it would be hopeless to grow Roses in the soil, so I removed it and brought good soil from a distance, but the expense was enormous. For one winter a farmer had three what are called "putts," or two-horse carts, at work all day hauling soil. Whilst the virtue of the new soil lasted I could get blooms, but now it has become stale and I cannot afford to replace it, so I am obliged to go on in the poor worn-out soil and do the best I can.

"Give it up," says one. "Why wear a collar that wrings?" says another. "Try some other flower that will take kindly to your soil, and leave the Roses to others." I cannot do it. I must grow Roses whether good or bad. They are the most glorious flowers of all, and the objects of my greatest admiration. If any brother rosarian who reads this feels any sympathy with me, and can advise me or help me in any way, I hope he will do so. The only thing I can think of is to get some clay and mix it with my light soil, but this will be a difficult matter to manage. The longer I live the more am I convinced of the futility of growing Roses in the same soil for a period of more than two or three years. Mr. Baker does it, it is true, but he gives a portion of his soil a thorough rest for a year every now and then; and he is blessed with a very rich red soil, which puts you in a good humour even to look at it. If one only could do it we ought to break up a piece of pasture every year for our Roses, and grow other crops on the former pieces; but where are we to get the pastures? No landlord will allow his pastures to be broken up. It makes one laugh in derision at the advice given by writers on floriculture, who say when speaking of a compost for any flower, "Take the top spit of an old pasture, if where Cowslips have grown so much the better." But where in the world are we to get the top spit of an old pasture? It is like telling a starving beggar to sit down at the feast of aldermen and then he will enjoy himself. Even the sides of the roads are now claimed by the roadmenders. You cannot get fresh soil except at a ruinous cost.

Such are a few of the difficulties which have made my Rose showing a failure this year, and which have turned me into a —WYLD SAVAGE.

GRAPES SCALDING.

WITHOUT going into the whole of the principles involved in the consideration of this question, it may prove interesting to those who are troubled by their Grapes scalding to note my own experience with Lady Downe's here.

The vineries are old, "with the old-fashioned system of heavy rafters, close sashbars, and small squares." The system of ventilating pursued is of the freest—a current of air at all times during the growing season playing through the houses. Early in the morning during warm summer weather the ventilators are opened to their full extent, and the whole of the doors are open. Ventilation is not reduced till the sun has left off playing on the houses. With regard to the amount of atmospheric moisture supplied, I am inclined to believe that no Grapes are grown with less. The Grape Vines are not syringed at any season, nor is there any moisture applied to any surfaces as borders, paths, or walls inside the vineries at any time, save when the borders are being watered or what may be spilt in watering plants early in the season. In order further to secure against scalding this season the pipes have been heated in dull weather. Under the above treatment Grapes which used to shank badly are all but cured of that disease. Golden Champion finishes to perfection, and withal in one division I cannot grow Lady Downe's without scalding.

Last season several bunches were entirely destroyed, this season the affection has not been nearly so bad, still it has been to such a degree as to make the bunches thinner than they ought to be. In the division next to the above Lady Downe's is very little affected. Why should such things be?—R. P. BROTHERSTON, *Tynninghame*.

OSMASTON MANOR CUCUMBER.

AFTER reading Mr. Harding's able article on Cucumbers in a recent impression of the Journal I have thought to say a few words in favour of Osmaston Manor. I have grown it now two seasons, and am so satisfied with it that I am inclined to reduce Telegraph and promote Osmaston Manor to the top of the list, which in my case is not a long one. I do not grow many varieties, but hearing from a high authority that Osmaston Manor was really good I was induced to try it. My list forthwith will be Osmaston Manor and Masters' Prolific: by growing these two varieties I find I am able to supply a rather heavy demand of good everyday-use fruit, with a few extra fine ones for exhibition purposes to boot. I need not go into details as to the many good qualities of Osmaston Manor; suffice to say that I am of opinion that it is the only real rival that Telegraph has to contend against.—W. W. B.

HYACINTH GLASSES.

WE have before referred approvingly to the new Hyacinth glasses of Messrs. Stevens & Williams, and subsequent ex-

Fig. 22.—Hyacinth Glasses.

perience with them enables us now to confirm all that we said in their favour. We have not only found the glasses admirably adapted for Hyacinth culture in the spring, but they are also elegant receptacles for cut flowers during the summer, or, indeed, at any season, as the accompanying illustrations sufficiently attest. Now that the Hyacinth-growing season is approaching the following sound instructions for growing the bulb in water, extracted from Messrs. Sutton & Sons' catalogue, will be seasonable:—

"It is of little consequence whether rain, river, or spring

water be employed, but it should be clean and of a kind not likely to become offensive. Fill the glasses sufficiently full that the bulbs will nearly but not quite touch the water, and place them at once in a dark cool place, that they may be encouraged to send their roots down into the water before they begin to expand their leaves. When the roots are growing freely bring them from the dark to the light, in order that their leaves and flowers may be developed in a healthy manner without being attenuated. Provide supports in good time; let the plants have as much light as possible, with an equable temperature. They are often injured by being kept in rooms that are at times extremely cold and at others heated to excess. Those who grow Hyacinths to perfection in glasses must remove them occasionally as circumstances may require, to prevent the injury that must result from subjecting them to rapid and extreme alternations of temperature. It is not desirable to introduce to the water any stimulating substances, but the glasses must be kept nearly full of water by occasion-

Fig. 23.

ally replenishing it as it disappears. If the leaves become dusty they may be cleansed with a soft brush or a sponge dipped in water, but particular care must be taken not to injure them in the process."

FRUIT REPORTS.

A GOOD deal was written early in the year upon fruit prospects, now the time has come for fruit reports. Some of the prospects have been fulfilled, others have not. Some people's realisations have been beyond their anticipations, others have been just the reverse. "Call no man happy till the day of his death," said the ancients. Let no pomologist rejoice or weep until the time of the fruit-gathering has come.

I have recently returned from a run through parts of Warwickshire, Worcestershire, and Gloucestershire, and in a fruit-growing sense I wish other counties resembled these. A large portion of the pasture land in these counties is planted with Apple and Pear trees, not always so thickly as to form orchards, though there are many, but with a certain number of trees at intervals, such wide intervals that injury to the lands there could be none, while an additional return of profit is certain. "Be aye sticking in of a tree, Jock, for while you are sleeping it will be growing." This simple sentence of Sir Walter Scott's is said to have led a great many Scotch lairds to plant woods, of which the benefits in appearance of the country and to the purses of the present owners of the soil are great. Why not, O English landowners, plant a few Apple trees in most fields, as they do in the counties I have named? Surely cider is as good as beer. But not only is the pasture land thus Apple-tree-sprinkled, but I noticed that often there was one row at least of Apple trees down the middle of a corn field, and very beautiful at this season of the year looked the well-grown fruit trees standing up amidst the upright ears of Wheat—two harvests on one land and at the same time. I must think this an admirable plan: as the Apple trees are in the middle of the field they are protected from the depredations of boys, for no boys would dare to tread over a field of corn;

then as soon as the corn is harvested there are the Apples ready to be gathered.

As to the actual fruit crop of this present season, my eye showed me that everywhere Plums were most abundant. There hanging in conspicuous numbers—and mark you, Plums unless very numerous are not conspicuous; but at railway stations, in orchards, in trim gardens, and many not very trim, the trees were bending under the weight of the fruit. Then the shop windows, particularly the fruit shops of Worcester, were filled with piles of Plums, far more Plums than all other fruits put together. Then I noticed this peculiarity as to Apples and Pears—while there were many trees with very little fruit on them, a large number with none at all on them, there were some few trees very heavily laden, and not of one variety either. I think this points to the fact that it was some case of particular shelter which such trees chanced to have, and that the shortness of crop was not owing to any such cause as non-ripening of the wood. The varying of cropping irrespective of variety is, I notice, the case hereabouts. In one garden a Marie Louise Pear is almost breaking down, in another there is not one Pear on the tree. My own private experience is, I see, quite the opposite to that of some who have written in our Journal. I had, for instance, a full crop of Summer Doyenné, and these quite early in July. This variety when gathered at different periods, say a dozen at a time, and ripened in the house, is, I think, by far the best early Pear, and its flavour as treated above, not being allowed to ripen on the tree, is excellent, and a dish of these very pretty Pears is most welcome to all. Then followed with me a good crop of Beurré Giffard, handsome in shape and colour but with a flavour somewhat peculiar, some people liking it very much, others positively disliking it; not so juicy either as the little Summer Doyenné, but in some respects greatly its superior. Jargonelles are a failure with me for the first time in many years, crop small, fruit small. Madame Treyve is coming on well, good in shape and a good crop, and there ends the list of my successes as to Pears. I have no Pears on many trees, for instance Seckle, Beurré Hardy, Beurré d'Amanlis, Winter Nelis, Napoléon, Williams' Bon Chrétien, Louise Bonne of Jersey, and Joséphine de Malines. I have a few on Soldat d'Esperen, Beurré Diel, and a fair sprinkling on Bergamot d'Esperen. This exceedingly partial crop as to Pears seems to extend to every garden and without respect to special varieties.

I now come to Apples. As a rule, the crop is very uncertain, one tree being loaded heavily, while another of the very same variety in the next garden has nothing whatever on it. Hawthornden has not failed me, but it does not show its wonted bright, smooth, unscarred face, but is all around me small and spotted. Having a particular eye to early eating Apples as being much needed, and very welcome at dessert and also in the schoolroom, and among young folks generally, I have been tasting and marking these kind of Apples very particularly. First and foremost in beauty, aroma, and flavour among the very early I must place Irish Peach. I am told that it is almost the only early Apple grown in Ireland, and verily brother Pat shows much wisdom. It is a few days after Margaret, and a fortnight behind Joanetting; but how superior it is to each of these! Joanetting is the first of summer Apples as to time, just as Summer Doyenné is among Pears, and this is a great point, for the first fruit, first ripe fruit, is from its earliness greatly to be treasured, as it is so much appreciated, but Irish Peach is vastly superior in all respects to Margaret. Then just at this time (August 23rd), we are eating Summer Golden Pippin, which I place next to Irish Peach. Verily our Doctor in his "Fruit Manual" is quite correct when he says, "This is one of the most delicious of summer Apples, and ought to form one of every collection however small. Flesh yellowish, firm, very juicy, with a rich, vinous, and sugary flavour." I would also add that the aroma is most pleasing to the nose, something after the way of Irish Peach. Duchess of Oldenburg is doing well with me, its handsome shape and beautiful striped sides and pearly bloom are most pleasing. On theory, I should place it, as Rivers places it, among the kitchen Apples, and not K. and D. as Richard Smith does; still D. only as it is placed in the "Fruit Manual." By the way, I have since writing the above line turned to Dr. Hogg's "Fruit Manual," and that although in the body of the book, the descriptive part, the Doctor speaks of the Duchess of Oldenburg thus, "An exceedingly early dessert Apple of the first quality," yet in the lists of select Apples, page 164, this Apple is placed among the kitchen sorts. I think this, perhaps our Doctor's second thought, is the best.

I have splendid crops on my pyramids of Cellini, Ecklinville Seedling, and Winter Hawthornden, and what gems of Apples these are! The shape and size of these attract the attention of even an Apple-ignorant person. Perhaps Cellini in shape and marking bears the bell, but Ecklinville has a colour of its own and very pleasing, and it is a weighty Apple as well as a large one.

And now for a sad trouble I have, and which has caused me to cook before their time all my Ecklinvilles and many of my Cellinis. A small bird, whether tomtit, or whitethroat, or linnet, for all three and more are blamed, contrives to pick a hole about half an inch from the stalk on the upper side as the fine fruit hangs. This hole is about the size of half a marble; then follows a thunderstorm, and this is a thunderstorm season, and the Apple rots. I have lost thus all my Ecklinvilles, many of my Cellinis. The birds have begun to attack Winter Hawthornden, Cox's Orange Pippin, and have spoiled several Duchess of Oldenburgs. Whatever Apple fairly ripe hangs conveniently is sought out and ruined. Unlike blackbirds and thrushes they are not easily scared, but creep under pieces of muslin hung over the trees. If the rain does not come the way is opened for the wasps, which are thus enabled to go on and devour. The little birds are so quickly gone that I have never found one actually eating. This from being a highly game-preserved county has no hawks, and I have many woods and shrubberies around, so that I am bird-pestered. As a proof how numerous birds are here, a friend of mine killed forty-two blackbirds and thrushes in his garden in two days. I fear, bird-lover though I be, I must get out my gun next year.

To proceed with Apples. I have heavy but somewhat blighted crops of Lewis's Incomparable; fair numbers of Devonshire Seedling, New Hawthornden, Cox's Orange Pippin; but not a Sturmer, an Alfriston, a Joanetting, a Striped Beeding, a Keswick Codlin, or a Tower of Glamis.

Gooseberries have been a poor crop. Raspberries and Strawberries excellent. Currants fair only; while Damson trees are blue with fruit.

I have paid some special attention to Raspberries, and can speak well of the plan of growing on wires as being handy to gather and easier of protection from birds. The delicate flavour of the yellow varieties, to say nothing of their beauty, should cause them to be more generally grown, and certainly yellow Antwerps fruit as freely as any red. Carter's Prolific is a noble berry, so Fastolf, and so also Fillbasket. But some sent me by a lady in Somersetshire with a dark stem, somewhat late in ripening, exceed any I have. Their name I know not, nor can I identify them by the "Fruit Manual."

Thus for the present end my words about fruit.—WILTSHIRE RECTOR.

P.S.—From a very good source I have heard this year of the great excellence of the Pitmaston Green Gage Gooseberry, but personally I am not acquainted with it.

DEVON AND EXETER HORTICULTURAL SOCIETY.

THIS old Society has attained its jubilee year, and after fifty years it has been found to have suffered a little from the vicissitudes of fortune. Wet weather on show days, an inadequate subscription list, a liberal prize list, and hospitable treatment of judges have all told their tale, and the funds are at their lowest. Under these circumstances the Society has been reorganised, and it is hoped that it will live for another fifty years.

The courteous Hon. Secretary, Mr. T. W. Gray, who has for forty years conducted the business of the Society, has retired, and his place taken by Mr. C. B. Sanders. The Society has presented Mr. Gray with a very handsome testimonial, and also given him a complimentary dinner.

This year there have been two Shows, one in June and the latter last Friday. The usual Rose Show has not been held on account of the state of the finances; however, on the 23rd inst. an exceedingly pretty Exhibition was held on Northernhay, and I do not think I ever attended a show where there was so much variety. Gladioli were exhibited by Mr. Kelway in fine form, Mr. Dobree of Wellington brought his matchless Dahlias, and Dr. Woodman filled one side of a huge tent with his splendid plants. Then in a large tent the Veitch memorial prize, offered for twelve kinds of vegetables, was competed for by a very large number of exhibitors, whose productions also filled one side of the tent. The prize was awarded to Mr. Drew of Powderham. In a smaller tent the centre table was occupied by the table decorations and the fruit, and I do not know whether I have ever seen a better show of the latter.

The table decorations were not so numerous as usual, and being confined to ladies the gardeners of the great county people could

not compete; still, what there was attracted much attention and was very good in quality. Miss Wish was the winner of the first prize. She showed three trumpet-shaped vases, filled for the most part with exotic Ferns, and if any fault could be found with her handiwork it would be that flowers were too sparingly used. The second and third prizes were awarded to vases which would perhaps attract the general public more from the beauty and variety of the flowers employed, but I can imagine no quieter, subdued, and cool decoration to put one in a good temper and to assist digestion at dinner than Miss Wish's.

The cut flowers were very good indeed. A prize of £5 for twenty-four bunches of not less than twelve varieties was offered by a gentleman in the neighbourhood, and this attracted great competition. Dr. Woodman showed in the best (according to my judgment) form, and such as I should suppose the giver of the prize desired to see. In a large box he put twenty-four bunches of three flowers of the same variety; and whether we regard the class of flower shown, the variety, or the excellence of the individual blooms, or the way in which they were set up, the eye of the florist could not help wandering in admiration of his stand. Perhaps a list of some of the varieties shown will not be unwelcome to some of your readers who may wish to have a guide for future competition. I know that such descriptions are a little tame, so I will let them off as cheap as possible. There were two Orchids—*Oncidium* and another, two *Ericas*, one *Dipladenia*, two *Allamandas*, two *Bougainvilleas*, two *Vincas*, *Rondeletia*, *Habrothamnus elegans*, *Ixoras*, *Clerodendron*, and that lovely hardy herbaceous plant *Agapanthus umbellatus*, which did no discredit to the grandees on each side of it, but stood her own well. This stand did not, however, get the prize, but one by Mr. Grant. I should not, however, call the winner's exhibit a stand, for it was a collection of table decorations, each set of flowers being shown in a separate glass vase. The judgment evoked much criticism, and I do not know quite on what principle the Judges went. Each glass vase contained, not three blooms of the same variety, but a miscellaneous collection of all sorts, in fact what may be called an *omnium gatherum*.

The Dahlias exhibited by Mr. Dobree were exceedingly good. In fact I do not remember seeing any finer ever exhibited. I regret to say, however, that Mr. Dobree does not intend to continue exhibiting these flowers. He no doubt finds, like I have done with Roses, that his ground wants a complete change. Some few years ago he exhibited Roses in as good form as he now does Dahlias, but no doubt for the same reason he relinquished growing them and took to Dahlia cultivation. I took notes of all his leading blooms. Besides the number required for exhibition he staged sixty varieties, and a finer lot could not have been put together. His best bloom was Christopher Ridley; this is one of Turner's, and is a dull crimson in colour, but of the most perfect form. Next to it was Julia Grieve. This in colour reminded me exactly of Homere, the well-known Tea Rose, but its form was far different, being as perfect as the other is imperfect. Julia Wyatt and John William Lord were both fine Dahlias. Of the yellows Canary was the best, but John Neville Keynes, whose name tells its origin, and Acme of Perfection were so like it that it was difficult to distinguish any difference. Mrs. Harris is a charming Dahlia; she is light lavender shaded with white, and has a more perfect form than we can believe "my friend Mrs. Harris" could have had. Sensation was worthy of the name as to colour: imagine a rich salmon with red edge, and each petal shaded with white. Baron Taunton is a Dahlia which must grow wild. It refuses to be cut and doctored, and so should be cultivated in every garden. In colour it is a somewhat deep lavender. Henry Bond, light purple in colour, and Willie Eckford, almost cupped in form and a dull ruby in colour, are both striking Dahlias.

Mr. Nation, who I believe lives at Taunton, was a good second in this class. Owing to the prize cards having no names upon them till late in the afternoon it is difficult to find out the names and addresses of the exhibitors, so that I hope any mistakes on this head will be forgiven me. His best blooms were Tiffany, salmon peach in colour, and good in form; John Bennett, scarlet shaded with yellow; Herbert Turner, the purest white, and one of the most striking Dahlias shown; Marchioness of Lorne, a most striking Dahlia, the ground colour canary, but each petal lined with peach; and Lady Gladys Herbert.

Mr. Kelway showed some splendid Gladioli, one of which he dedicated to Mrs. Dobree. I will not weary your subscribers or take up your space by giving the names of the various spikes, as it is a very difficult matter to make such lists interesting, and I doubt not most of your readers have often seen the same blooms; but I must give you the names of a few of the splendid plants which Dr. Woodman staged. There was no prize offered for stove and greenhouse plants, so he did all for love and good fellowship. Well did the old firm come to the front. He showed a splendid specimen of *Allamanda nobilis* and *Stephanotis floribunda*, and his *Ixoras* were also very fine, but his Tree Ferns and exotic Ferns bore away the palm. He had three grand specimens of *Gleichenia rupestris*, *Mendeli*, and *dichotoma*. His *Dicksonias* and *Adiantum concinnum latum* attracted the notice of everyone, while his Pitcher-plants, and *Crotons*, and *Marantas* were too numerous to

specify. The trilobed *Croton* named after the Premier before he left the Commons was good, but the variety named *volutum* was more striking. Every leaf was curled and formed into a complete bow, and the effect was very curious. Perhaps there might have been more flowers and fewer foliaged plants, for when the sun was hidden by thunder clouds the effect was a little gloomy, but the exhibit was a very grand one. In another tent Mr. Robert Veitch staged a large collection of foliage plants, but here hardly any flowering plants were to be seen.

Most of the Exeter nurserymen staged a large number of Roses not for competition, but the blooms were more conspicuous for quantity than quality. There was a fair competition for Roses; but, the giants staying away, pigmies like myself were left to represent the queen of flowers, and the quality may be imagined. *Philoxes*, *Asters*, *Geraniums*, and other autumn flowers were all largely shown, but were not so good as I have seen them in former years.

The day was not all that could be wished, as a heavy thunder-storm broke over the city as the Judges made their rounds; but afterwards the sun came out, only the sky looked threatening enough to keep many visitors away, and I fear the old Society's jubilee year will have proved a disastrous one to its finances.—WYLD SAVAGE.

ROSE CULTURE ON THE ISLAND.

WE Portsmouth people consider the Isle of Wight as much "the Island" as does London a visit paid to it as "going to town," and I propose now to record a short visit lately paid to one of the chief Rose-growers on the Island.

Crossing the "silver streak," which was rather disposed to make itself unpleasant, as it has often been doing this turbulent August, I landed on Ryde's long pier; and presently, by a most leisurely little single-line railway, was carried to a place which I shall not further indicate except That Parish. Parish and church seemed very perfect indeed of their kind, and admirably suited the one to the other. Eighteen years ago a bare hillside, the vicarage and vicarage garden is one of the most charming spots imaginable; nor is the closely neighbouring God's acre a whit less engaging or tenderly cared for. As I mounted the sunny hillside through preparatory cottages I saw tokens on every side that people as well as pastor loved well their Roses. Glorious old "John" and Lamarque were robustions in vigour. Some walls, however, were less honourably occupied. I could not but feel, while looking at them, very like that sated epicure regarding a countryman pegging away in an eating house. "My dear fellow, how can you waste that glorious appetite of yours upon a commonplace leg of mutton?" How can they waste such situations upon such intense rubbish? for is it not as easy to grow a good Rose as a bad, and is not our Island the garden of England? Such Myrtles as I saw, worthy rivals of those which fringe the outskirts of Lebanon, and Verbenas 10 feet high, and Fuchsias 20 feet well up under the windows! while rare specimens of the Cupressus, and trees of which I cannot write without displaying my ignorance—*C. Lambertiana*, and *Laurenceana*, and so forth—enriched the house and garden with a pleasing shelter, the only one thing there which Nature had left to be desired.

My hospitable host led me forth after luncheon, and we lionised in various parts—first and last, and especially, of course, the Rose regions. Some of these in the case of *Maréchal Niel* and *Lamarque* were very close under the roof. Céline Forestier appeared as an energetic climber. *Triomphe de Rennes* was in rude health; *Climbing Devonensis* gigantic. In short there was every appearance that *Teas* and *Noisettes* may be grown here with special advantage and to very great perfection. To my surprise the Hybrid Perpetuals, whether on Briar or Manetti, were not equally flourishing. This garden, however, like others elsewhere, had received a check in the spring from which many Roses had never rallied. I was also surprised to be told by my host, whose trophies withindoors testified to his success as an exhibitor, that some Roses even in this favoured spot could not be persuaded to grow at all. *La France* for example, though it flourishes elsewhere; *Marie Baumann*, universally found unsatisfactory, a loss indeed for the islanders; *Alfred Colomb*, *Charles Lefebvre*, *Duke of Wellington*, *Louis Van Houtte*, and most of the *Verdier* strain he did not succeed with. It is a curious inquiry whether any of these specially object to sea air. I can testify to their having had every other advantage. On the other hand *Serenye*, *Pierre Notting*, *Thomas Mills*, *Marie Rady*, *Marguerite de St. Amand*, and especially *Capitaine Christy*, were spoken of in terms of considerable satisfaction.

Returning to Ryde somewhat later I was glad to find the "silver streak" rather more reasonable, and regained my quarters on the other side after a very pleasant day. May my hospitable entertainer when he reads forgive this, I trust not too intelligible, intrusion into his Rose privacy.—A. C.

GLAMORGANSHIRE HORTICULTURAL SOCIETY.

THE sixteenth annual Show of this Society was held at Cardiff on the 21st inst. When this Society was formed its pretensions were small, but under the able and courteous secretaryship of Mr. Payne, with the help of an excellent Committee, it has gradually expanded until it is now one of the best provincial shows in the kingdom.

The Show now under notice was much superior to last year's Exhibition both in extent and quality, and the arrangements were also much more perfect. The exhibits were so numerous that it took six large tents to contain them. The largest tent, some 200 feet in length, had the interior arranged in a most effective manner. The centre consisted of a beautiful fountain with a large basin surrounded with virgin cork; next to this there was a band about 2 feet in width of Maidenhair Fern, and then a margin of choice cut flowers set in a cushion of green moss. This was justly much admired, and so were the small moveable beds, which were elegantly filled with flowering plants in pots plunged in cocoa-nut fibre and lying a short distance from the centre figure. We were so highly pleased with these moveable beds that we remarked to several gardeners how useful a number of them would be about private gardens to shift about and arrange as desirable on such occasions as garden parties, &c. On each side of the fountain large groups of plants, Tree Ferns, Palms, and other choice plants of this description were placed in the centre of the groups, and the whole was banded with zonal Pelargoniums, Fuchsias, Balsams, &c. The effect of this combination was extremely imposing; and although Mr. Payne is not a practical gardener, his ideas of distributing plants in an artistic manner to insure the very best effect were strongly exemplified here.

The other tents were similarly attractive, only on a smaller scale. There was a broad stage raised for plants in the centre of one of the tents, however, which was not at all in harmony with the others. The plan was good enough, but the materials with which it was carried out were bad, and as the Society is in such a flourishing condition it would be a simple matter, and one sure to be appreciated, if stages and mounds on which to arrange the plants were made permanently with earth and turf as they are for the shows in Regent's Park and at South Kensington.

In the open plant class for twelve stove and greenhouse plants Mr. J. Cypher, Cheltenham, came in first (£15); second Mr. Williams, Worcester (£10); third Mr. W. Pilgrim, Cheltenham (£5). All the plants in these collections were of the usual class shown by those well-known exhibitors, and all the principal prizes in the open class for smaller numbers of plants were pretty evenly divided between Mr. Pilgrim and Mr. Cypher. In hardy Ferns Mr. Fowler, Pontypool, was first; and Sir George Walker, Castleton, second. In the amateur plant class Mr. Pilgrim was again prominent and won many of the first prizes. Lord Tredegar, the Marquis of Bute, Mr. Jones, Maindee Park, Newport, and several others, also showed in a very creditable manner in this class.

In the section for gentlemen not having regular gardeners there were some excellent Fuchsias, Geraniums, Achimenes, Balsams, and cut Gladioli, Asters, &c., exhibited; Mr. R. W. Williams, Newport Road, Mr. J. Watson, Mr. E. Fowler, Mr. J. T. Francis, and Mr. J. Elliot being awarded the principal prizes. In the open section for cut flowers Roses were the most attractive feature. Here Mr. W. Earl, Newport, secured the leading prize; Mr. Stephen Treseder, Ely Road Nurseries, Cardiff, second; and Mr. Davidson, Hereford, third. Some excellent blooms were shown by each of these gentlemen.

In the special prize section for Roses, the three prizes offered by Mr. Treseder for eighteen blooms, the first prize was well won by Mr. Pettigrew, gardener to the Marquis of Bute; the second by Mr. Thomas; and the third by Mr. Crosslin, gardener to Lady Clive. Tea Roses were also shown well by these exhibitors, but space will not allow us to go into detail on their merits, we must simply say of all cut flowers that they were shown in high style.

The table decorations were a splendid feature of the Show; Mr. Ellis, nurseryman, Cardiff, being first, and Mr. Slocombe, Canton, Cardiff, second.

The fruit was not wholly of the very first description, but this could hardly be expected, as the prizes in this section and for vegetables are much too small to bring out a really first-class competition; and as every person knows there is nothing gives tone to a show more than fine fruit, we would suggest to the Society that great benefit would be sure to result if the prizes here were augmented. For nine sorts of fruit Lord Tredegar was first, Lieut.-Col. Page second, and Mr. J. Barnes, Hucclecote, Gloucester, third. For the Queen Pine Apple Mr. Pettigrew was first, and Mr. J. Muir, gardener to C. R. M. Talbot, Esq., M.P., Margam Park, second, with nicely swelled fruit. Muscat Grapes were not

shown well, but in the class for any other white Grape Mr. Pettigrew was placed first with some splendid bunches of Foster's Seedling; and Mr. Crosslin second with large fine-coloured bunches of Buckland Sweetwater. For Black Hamburgs, three bunches, the position of these two prizetakers was reversed. For the collection of Grapes Mr. Pettigrew had first for a really fine lot, consisting of two bunches each of Muscat of Alexandria, Madresfield Court, Foster's Seedling, Buckland Sweetwater, Black Alicante, Gros Colman, and Black Hamburg. Peaches, Nectarines, Plums, &c., were small in size as a rule, but were shown in abundance. Melons were also plentifully shown, and so were all sorts of vegetables, the competition for everything here being exceedingly keen.

Altogether this was a surprisingly good Show, and this was the opinion of several gentlemen who were down from London judging, who told us they had seen nothing to equal it in the provinces, and commented highly on Mr. Payne's successful abilities in connection with it, and in all this we heartily concur.

There is only one thing we would be pleased to see better conducted, or stopped altogether at future shows, and that is the way in which one exhibitor shifts about another one's produce, and one taking advantage of the other's absence to change positions. This, of course, is very injurious to fruit in bruising and rubbing. When once an exhibitor has placed his productions on the table they should be entirely out of his hands. This we are confident would be just, and would give satisfaction to all parties.

We must not omit to state that Messrs. Cranston & Co., King's Acre Nurseries, Hereford, sent a splendid collection of Roses for exhibition; and Mr. J. Muir, Margam, was awarded a special prize for a fine collection of Oranges and fruit of this tribe, which were garnished with their leaves and blossom, and were greatly admired.—A WELSH READER.

WINTER TREATMENT OF STRAWBERRIES IN POTS.

THE potting of Strawberry plants for next season is now pretty well at an end. They are placed upon a level bed of coal ashes in narrow strips with intervening spaces for convenience in watering, weeding, and picking off runners, to all of which diligent attention will be given. Meanwhile we must not forget to give a thought to what we are to do with them in the coming winter.

At one time it was the rule to pile the pots upon their sides one upon another; but I never liked the plan, for the plants always suffered from drought in some degree, and I was very glad when a lot of Melon frames could be spared to afford the plants shelter right end upwards. Now, thought I, we shall be right; the glass lights can be drawn off, always excepting during heavy showers of rain or snow or during frosty weather, when they can be shut, and we can always give water if requisite, or throw on litter if frost falls very severe. But I was disappointed, for sometimes the glass lights were left on when they should have been off, or off when they should have been on; and worse still—indefinitely worse—many of the plants suffered so much from careless watering that many of the roots perished outright, inducing much subsequent feebleness and an indifferent crop of fruit, or rather no fruit at all upon many plants. A reform was needed, and a little cogitation soon brought conviction that all this coddling was wrong. I reasoned thus: The Strawberry is not exactly an aquatic, but then it never suffers from rain in winter unless the soil becomes waterlogged; it is, moreover, perfectly hardy. Why, then, protect it or keep rain from it? On the approach of winter, therefore, a bed of coal ashes was spread upon a level space sufficiently elevated to be safe from any accumulation of water. Upon this the plants were placed close together, the spaces between the pots packed full with some half-decayed leaves, and they were settled for winter, requiring only a glance after heavy rainfall to see if any pot was waterlogged, and in severe frost a slight covering of dry fern. The plan proved a complete success, for when the plants came in due course to be taken into the glass houses the full plump crowns, stout green foliage, and abundant white roots gave ample promise of the fine crop of fruit which was subsequently brought to maturity.—FRAGARIA.

CORDICEPS ROBERTSHI—THE RATA TREE.

I HAVE read with interest the Journal of the 14th February last, containing an account of the New Zealand vegetable caterpillar, and I may add that this curious creative anomaly is invariably found at the foot of the Rata Tree—not a plant, but a great forest tree. The fungus in first planting itself on the caterpillar does not kill it at once, but the animal can wriggle till its vital powers become exhausted.

I am not a scientific botanist, so am unaware whether or not observers have remarked the strange analogy between the Rata and the fungus of the vegetable caterpillar.

The Rata is an epiphytal plant at the commencement of its life. The seed is blown about, and a single one may fall on a great Matai, Totai, or other forest tree. The seedling germinates, grows, clings to, and at length envelopes the trunk. In the course of a century or two the Rata will be seen to have struck its roots into the ground, to have encased its "mother," whose choked and withered head will be seen mingling with the giant "child's" branches. At length the original forest tree—it may be 100 up to 200 feet in height—will have rotted away, and now appears the Rata, a gigantic and stately usurper, at the same time probably one of the handsomest objects in the forest. This is more particularly the case in North Island.

Thus the Rata is a vegetable killer, and at its foot is the fungus which is the animal killer, as your article has correctly stated—J. T. THOMSON.

PEAS IN 1878.

THE Pea season of 1878 is very nearly over. Although a few may come in after August most of the main sorts have been

Fig. 24.—*Erica metalflorea bicolor* (see page 170).

gathered, and now that the matter is fresh before me I would like to say a few words on our Pea crop generally this year. I may state that we never had better Peas. They have been the admiration of all who entered the kitchen garden. Sangster's No. 1 and Little Gem were sown on the 2nd of February. The first is a good old Pea just for one early sowing, but it stands no chance with others afterwards. I am beginning to think that none of the very dwarf sorts are worth growing. Certainly they do not take up much space, but the pods they yield are few. Nor do the dwarfs continue bearing for any length of time, while the kinds which grow about 6 feet begin bearing about a foot from the ground, and it is a long time before they finish-off at the points. We gathered fresh Green Peas from some of our tall sorts more than a month this season; for that reason we prefer all varieties growing from 5 to 7 feet in height. But it is very seldom Peas come exactly to the figures placed against them in catalogues. In rich soil many of them grow 2 feet higher than they are said to do, while in poor soil they do not attain their normal height. But the worst thing that any person can do is to grow Peas in poor soil, as there the produce is light, the quality inferior, and

the length of time of bearing very short. When the soil is not rich in which Peas are to be sown, a trench 18 inches deep and 2 feet wide should be taken out and the opening filled up with a mixture of half loam and half cow dung. Many rows of ours were prepared in this way this season, and it is the best plan we ever saw tried.

We sowed the seed much thinner this year than we ever did previously, and this also answered very much better than the old way of laying the seed close in together. Many of the kinds we paid 3s. 6d. a pint for. The seeds of these were planted singly about 3 inches apart to make them give a succession of sowings, and the crop from these has been more abundant and the pods much finer than those sown closely. I may state, however, they were not planted in single rows 3 inches apart, but in three rows the width of the spade in this form: . . . : From one pint of Culverwell's Telegraph planted in this way the produce was so great that we gathered from four to five bushels of pods, and now we have saved about six quarts of seed. Carter's Challenger treated in the same way was just about as fine. We have grown this year over two dozen of the best sorts known, and placed Culverwell's Telegraph first on the list. The pods are produced in great abundance, they fill rapidly, and become very large in size, and the peas are superb in flavour. Every person who saw it in the kitchen garden here, and who grows Peas, took its name down to have it next year. This is referring to its qualities as an early and mid-season Pea. Next season when I shall have plenty of seed I will try what it will come to very late. Carter's Challenger is an excellent new Pea. It does not grow so high, nor are the pods so large as Telegraph, but they are even more numerous, and they fill as well, and the peas are equally good in flavour. Carter's Little Gem has not proved equal to our expectations. The pods did not fill evenly and they were very scarce. It bears a resemblance in some respects to Dr. Maclean and this has not secured a place with us for another year. G. F. Wilson is another not quite good enough for us. Veitch's New Criterion is decidedly worth trying. It has come quite up to the representations of it as a midseason Pea, and it promises well for late. The flavour is very fine and the pods fill well. Laxton's Fillbasket Pea resembles Carter's Challenger very much, but it is inferior to it in every respect. Laxton's Superlative has filled well and produced pods of unusual size, but this is the best of it, as the flavour is very inferior. Dickson's First and Best and Dickson's Favourite have done well this season as they always do. Hundredfold is another we never think of avoiding. Veitch's Perfection and Champion of England do not stand quite so high in my estimation as in some people's. Ne Plus Ultra is a valuable late sort. Wilson's Vanguard is a moderately good Pea, and it comes in earlier by two weeks than Sutton's Duke of Edinburgh and Sutton's Duchess of Edinburgh—two promising Peas, but from the few we grew of them this year we cannot give a definite opinion of their merits for general purposes. Some of the others we have grown do not call for special mention here.

All the varieties were grown together and treated in the same way. Those which grow above 6 feet are benefited by having their points nipped out at that height. Those so treated podded to the very top, and a few we left to see what height they would attain ascended about 10 feet and doubled over at the top of the stakes downwards. Of course the greater part of the crop was lost; besides, the pods did not fill either well or so quickly as where the haulm was stopped.

As a rule Peas are ready for gathering sixteen weeks after sowing; and although I have the length of time marked down which it took all our different kinds to come in, it would serve no useful purpose to publish the notes, as it is well known Peas vary in their time of coming-in in different places and according to circumstances.—A KITCHEN GARDENER.

A FRUITFUL ORCHARD HOUSE—WOODSTOCK KIDNEY POTATO.

I HAVE rarely if ever seen so good an example of an orchard house as one I saw the other day at Sutherlands, the residence of Mr. Martin J. Sutton, at Whitley near Reading. It is nearly 300 feet in length, a lean-to, about 6 or 8 feet wide. There is a double row of trees, one on the wall and the other on a low trellis in front, with a narrow walk between, and on the top bar of the trellis Tea Roses are trained: thus every bit of space is utilised. There was a splendid crop of Peaches, Nectarines, and Plums, all evenly set, well coloured, and ripening well. I have seen a good many orchard houses, but never one

that seemed so thoroughly to fulfil the idea of what a good and profitable one should be as this. The whole place, which has been considerably altered and improved, evinces the care and taste which might be expected from a member of this well-known firm.

At the same visit I took notice of what I believe is likely to be a valuable new Potato, one of Mr. Fenn's raising—Woodstock Kidney. I saw several roots of it lifted on the trial grounds, and have had a few in my own garden. The tuber is smooth and handsome, very free from eyes, and, unlike many that are only good to look at, it is a splendid cooking Potato, mealy and white. The number of new, or so-called new, Potatoes is legion, but the number of really good ones very select. Woodstock Kidney is, I imagine, likely to be a favourite with all who value a really good tuber. I say nothing as to immunity from disease, for I do not believe in it. Planting early and lifting early are the only means of warding it off.

—D., Deal.

INTERNATIONAL HORTICULTURAL EXHIBITION SOCIETY OF SEINE-ET-OISE, VERSAILLES.

AUGUST 25TH TO 28TH.

It has been said that were Paris blotted from the face of the earth, leaving nothing behind it but the palace and gardens of Versailles, that this fairy-like structure—with all its promenades, fountains, and artificial lakes—would alone repay the visitor for his journey from England.

Versailles abounds in historical associations, and some of very recent date. It was here that Her Most Gracious Majesty Queen Victoria was received, with all the honour and brilliancy due to her, by the late Emperor Napoleon III., 1855. It was the head quarters of the German army during the late sanguinary war, and in this palace King William of Prussia was proclaimed Emperor of Germany in the midst of his generals, and surrounded by his victorious army, in January, 1871.

The Exhibition was held in an enclosure at the foot of the magnificent terrace leading from the palace front. The collections of choice exotic and other flowering plants were arranged in an immense almost circular tent, covering fully the space of an acre. The interior was tastefully laid out with gracefully sweeping spacious walks, which passed by circular, oval, oblong, and other shaped raised mounds, on which the plants were disposed, the whole presenting a very imposing appearance. Around the two massive columns which supported the vast canvas structure were some large Palms from M. Chantin of Montrouge, Paris. Very near this central oblong bed were four circular beds, one of which contained the magnificent and unique collection of plants from the Chelsea nurseries of Messrs. Veitch & Sons. These plants were not in competition. The effect from the entrance to the large tent was charming in the extreme. The corresponding circular bed to this was arranged with collections of Orchids and decorative plants sent by Mr. Wills, Onslow Crescent, Brompton. Mr. Wills was a very large and most successful exhibitor at this Show, and his collections added greatly to the extent and beauty of the Exhibition. Mr. Wills not only received the grand prize of honour, a Sèvres vase, valued at 800 francs, but obtained fifteen first prizes and one second from the sixteen classes in which he competed. This speaks well for English enterprise and English horticulture, and especially when we consider the difficulties of reaching Versailles—the plants shut up in closely packed baskets and vans, undergoing the journey of nearly a week by road, rail, and water. From a collection of over two hundred plants sent by Messrs. Veitch and Sons not a leaf nor a bloom was injured, and on Saturday morning the collection looked as fresh as when exhibited at South Kensington. The task for Mr. Wills was even greater, from the greater quantity of plants staged by him. The collections were the admiration of the multitudes of fashionable visitors which crowded the tents directly after the Show was open to the public at 3 P.M. on Saturday, and from early morning on Sunday until its close.

In addition to the prizes obtained in the classes M. Mozer, Versailles, received the prize of honour, a gold medal valued at 500 francs; M. M. L. Duval, Versailles, was awarded a prize of 300 francs, and M. Perrette, Bellevue, 200 francs. M. C. Lemoine, Angers, received the prize of Madame Heine, valued at 150 francs, and Messrs. Chantrier freres and Boivan fils 100 francs. Several other medals were awarded to foreign exhibitors. Although the Messrs. Veitch did not compete in any of the classes, the Jury marked the high estimation of the Chelsea collection by presenting them with a work of art.

The centre plant of their group was a large specimen of *Anthurium Brownii*, surrounded with four magnificent *Nepenthes*—*Hookeri*, *Rafflesiana*, *intermedia*, and *Chelsoni*. Grouped on one side of these were *Nepenthes Courtii*, *hybrida maculata*, *ampullacea vittata major*, *Sedeni*, *zeylanica rubra*, *Stewartii*, *Kennedyana ampullacea*. A fine plant of the beautiful and rare *Araucaria Neipreschkis* was very conspicuous and much admired. *Alocasia*

Thibautiana was prominent by its beauty, while that superb *Anthurium Veitchii*, with bronzy foliage quite 3 feet 6 in length, formed an exquisite background for Mr. Dominy's greatest triumph of hybridisation *Cattleya Veitchiana*, to which *Cattleya gigas Normani* with three very large blooms formed a fine companion; and in charming contrast was *Phalænopsis grandiflora* with snowy white flowers overshadowing a beautifully coloured example of *Croton Prince of Wales*. Long spikes of *Odontoglossums Alexandræ* and triumphans fell carelessly into the bosom of a grand plant of *Lomaria discolor bipinnatifida*. A group of *Cypripediums*, amongst which were *Sedeni*, *seligerum*, *ænanthum*, *calanthum*, *euryandrum*, and *Ashburniana*, were backed up with *Croton Truffautianus* and *Dracæna speciosa*; *Masdevallia Veitchii*, *Odontoglossum Laurenceanum*, *Epidendrum vitellinum majus*, and *Cattleya Dominana* being arranged in front of them. *Erythrina marmorata* and *Anthurium hybridum* stand out bold and effective. A fine plant of *Anthurium Warocqueanum*, with foliage 3 feet in length, was in splendid condition, and arranged alongside of it were *Cattleya hybrida picta* and *Oncidium prætextum*. The lovely *Dendrobium formosum*, with fourteen snowy white flowers, was on the front side of the group, also a plant of *Lapageria alba* was conspicuous by its purity. *Sarracenia Stevensi*, *Drummondii*, *Chelsoni*, and *purpurea*, intermixed with *Darlingtonias*, *Cephalotes*, and *Droseras*, were gracefully arranged in a bay on the opposite side of the pitchers, amongst which was exhibited for the first time a seedling *Sarracenia formosa*. It is the result of a cross between *S. psittacina* and *S. variolaris*, and has the erect habit of its parent *variolaris* with the colour of *psittacina*. It is quite intermediate between the two and a valuable novelty. *Dracæna Robinsoniana* and *Yucca filamentosa aurea elegantissima* were also very much admired. A miniature collection of *Bertolonias*, *Sonerilas*, and *Goodyeras* were grouped together on the one side, while on the opposite side an extremely rare collection of insectivorous plants commanded general admiration. *Adiantum farleyense*, *Liudemannianum*, and other Ferns were tastefully interspersed in the foreground, while very fine spikes of *Oncidium stelligerum*, *incurvum*, and *Odontoglossum hastilabium* were weeping over the top of the group.

For the best plant in flower Mr. Wills was awarded the first prize for a specimen of the new and distinct *Dendrobium superbiens*, having three good spikes and twenty-five expanded flowers. In the corresponding class for the best fine-foliage plant the same exhibitor won first honours with a massive plant of *Dracæna Goldieana*, without doubt the finest plant in Europe; its colouring and markings were indeed grand. In the class for a collection of new and rare plants exhibited for the first time in France Messrs. Wills, Duval, and Desbois competed. Mr. Wills was awarded first honours also for a collection of thirty-six plants, which comprised *Dracænas Goldieana*, *Willsii*, and *Fredericki*, *Ficus Grelli*, *Anthurium Warocqueanum*, *Calyptronoma Swartzii*, *Sarracenia Moorei*, *Bromelia Binotii*; *Crotons Prince of Wales*, *Mutabilis*, and *Earl of Derby*; *Ceterach aureum*, *Nephrolepis Duffii*, *Davidsonia pungens*, *Curmeria Wallisii*, *Æchmea Veitchii*, *Nepenthes superba* and *Hookeriana*, *Bertolonia superbissima*, *Acalyphas musaica* and *Macafeana*, *Sarracenia Moorei*, *Alocasia Johnstonii*, *Asplenium ferulaceum*, *Anthurium Veitchii*, *Goodyera Rollinsonii*, *Anæctochilus ornatus*, *Grevillea filicifolia*, *Bowenia spectabilis serrulata*, and *Coleuses Exquisita*, *Lord Falmouth*, *Kentish Fire*, and *Fascination*. In the class for three ornamental plants not in commerce twelve collections were staged, Mr. Wills again securing first honours for large and well-coloured specimen *Dracænas Leopoldii*, *majesticum*, and *albo-marginata*; he was also placed first in the class for a single plant in or out of flower, remarkable for its good culture, with a large plant of *Sarracenia flava maxima* with over sixty developed tubes. M. David was placed second, and M. Lacroix third. In the class for an unlimited collection of foliage plants remarkable for their good culture there were four competitors; Mr. Wills again secured chief honours. In the collection we noticed a very fine *Nepenthes* with over thirty pitchers; *Sarracenia purpurea*, remarkable for its deep brown colour; a pair of large *Yucca filamentosa variegata*, *Caladiums Princess Royal* and *Prince of Wales*, *Crotons majesticum* and *Earl of Derby*, several *Bertolonias* and *Sonerilas*, *Anthurium Williamsii*, and several of the new *Dracænas*, richly coloured.

Ferns were not numerous exhibited, and with the exception of Mr. Wills's first-prize collection of ten varieties the plants were small. The Brompton plants were large and well-grown specimens of *Davallia Mooreana*, *Adiantum gracillimum*, *Lomaria gibba*, a *Gymnogramma*, *Cyathea Dregei*, *Microlepia hirta cristata*, *Gleichenia Mendeli*, a *Pteris*, and one or two others. In the classes for five Palms and a collection of Orchidaceous plants Mr. Wills was the only exhibitor, and was worthily awarded the first prize in both cases. His Palms were grand and well-finished specimens of *Cocos Weddelliana*, *Phoenix reclinata*, *Plectocoma assamica*, *Phoenix rupicola*, and a very beautiful plant of *Pritchardia grandis*. His Orchids were arranged in the centre of the circular mound, corresponding to Messrs. Veitch, and comprised about sixty plants, amongst which we noticed good examples of *Oncidium flexuosum*, *Odontoglossum Alexandræ*, *Saccolabium Blumei majus*, *Vandas*, *Epidendrums*, *Maxillarias*, *Aërides*, *Masdevallias*, *Cattleya Eldo-*

rado, &c. Arranged around these was a collection of decorative plants, consisting of Aralias, small Palms, Reedias, Gloxinias, Ferns, and such-like furnishing plants, the whole being edged with a *Pyrola*, broken at intervals with Begonias.

In the class for the best collection of *Dracenas* M. Lemoine received the first prize, and Mr. Wills the second, MM. Pigny père et fils being placed third. M. Lemoine here excelled Mr. Wills in both size and numbers, there being no limit named in the schedule, but many of them lacked the colour of Mr. Wills's specimens. The best plants in the first-prize collection were Gladstonei, very well coloured; Baptistii, Andersonii, Youngii, Mooreana, and several of the newer varieties. Mr. Wills exhibited *picturata*, Fredericki, terminalis alba, Tellingi, recurva, Elizabethae, regalis, Berkleyi, ignea, Renardae, amabilis, aurantia, Willisii, salmonæa, Bausei, stricta alba, Mrs. Causton, Mrs. Bause, Mrs. Wills, Thompsoni, venusta, Cantrelli, and Goldiana.

Perhaps one of the finest collections of six specimen *Crotons* ever exhibited in France was that staged by Mr. Wills on this occasion. The plants were from 4 to 6 feet high, and were grandly furnished to the bottom of the pots and beautifully coloured. They consisted of Jamesii, Prince of Wales, Queen Victoria, Volutus, Andreanus, and Majesticus. For the best collection of *Crotons*, numbers unlimited, MM. Chantrier freres wrested the laurels from Mr. Wills, both exhibiting well.

From the well-known establishment of M. Linden, Ghent, Belgium, came an admirable collection of large fine-foliaged plants, including *Aralias* elegantissima and Veitchii, *Kentia* Lindeni, *Artocarpus grandis*, *Dracæna* "Basanore," *Cocos Bonnetii*, *Anthurium crystallinum*, *Dieffenbachia imperialis*, and *Pritchardias* macrocarpa and aurea. Adjoining the large marquee were several tents of smaller dimensions, MM. Truffaut fils, Versailles, entirely filling one with elegant foliage plants. An oval group of *Dracenas* near the entrance was admirably arranged; the varieties grouped together were amabilis in the centre, followed by stricta and terminalis, with an outer ring of Guilfoylei. In this bank there must have been several hundred plants. The sides and background of this tent were decorated with *Palms*; falling to the front there were grouped numerous varieties of *Dracenas*, all splendidly coloured and well finished. This tent was altogether effectively arranged, and fully displayed the wealth of M. Truffaut's establishment. M. L. Duval, Versailles, was a great exhibitor. His collection of *Gloxinias* was one of the most striking features in the Exhibition. There were about 160 large plants arranged together on an oval mound with the pots slightly plunged in the soil; a few small *Adiantums* were dispersed amongst them, and near the edge was a ring of *Selaginella formosa*, with an outer ring of cut blooms of *Gloxinias* placed in small bottles. They were for the most part new varieties representing every colour and marking imaginable. We noticed the following as particularly worthy of further cultivation—Mont Blanc, Boule de Feu, La Charme, Delicatum, Madame Cardozo, L'Éclair, Harry Veitch, Sarah Bernard, Madame Duval, M. Truffaut, and Richard Wallace. On the opposite side to these was a similar bank of *Achimenes* from the same exhibitor, and several meritorious collections of ornamental and other plants.

From M. Poirier, Versailles, came exceedingly well bloomed collections of both double and single-flowering *Pelargoniums*, pyramid *Heliotropes*, collections of *Petunias* and *Verbenas*. The banks of double *Geraniums* arranged by this exhibitor were composed of well-grown plants of dwarf dense habit with excellent foliage, each plant having from six to a dozen good trusses of flowers. Deputé Berlet, Guillaume Mangilli, Lucie Lemoine, Deputé Viox, Madame Thiers, a salmon *Emilie Lemoine*, Asa Gray, and Litre were amongst the most noteworthy. Near this collection were two banks of *Tuberous Begonias*, one on either side, with a smaller central mound of well-flowered *Gloxinias*. The whole of the plants were plunged in the soil to the depth of the pots, an arrangement that has much to commend it. Some beautifully coloured *Amaranthuses*, *Coleuses*, *Petunias*, *Caladiums*, and *Asters* were arranged in bays and curves around the sides of the large tent. One very striking feature in the centre of this arrangement was a collection of well-bloomed *Neriums* (*Oleander*) *Madoni grandiflorus*, *Augustine*, *coccinea Mabirki*, *Hacvile*, *alba maxima*, *roseum*, *aurantium*, *Single White*, and *Madame Peigre*. This old-fashioned plant, which was once a great favourite in England, is well grown in France, and may be seen in quantities in the markets, where it makes a most effective display.

Roses were very poor, and the style of exhibiting them was most unattractive. The blooms were arranged in long tubes affixed in a kind of framework with about ten bars across, and when filled with cut blooms forms a dense sloping mass; when empty it resembles a hurdle. Paul Neyron was conspicuous for its size, but all the rest were very disappointing to English growers. The best blooms came from M. Margottin, Bourg-la-Reine. Some of the collections were arranged in bottles—a very primitive method. *Gladioli* were very fine and numerous exhibited, but the spikes were exhibited in bottles of water. *Zinnias* and *Dahlias* were excellent; the flowers were very round, even, and massive. The same remarks apply to *Asters*, which were much finer than are generally seen in England.

FRUIT.—Both Apples and Pears were extensively shown, and nearly every variety was legibly named. The fruit was large and well coloured. Grapes were very inferior to those we are accustomed to see at home exhibitions. The varieties were those grown principally for making wines. Figs were very large and fine, especially a collection of *Rouge de Figue* and *Grosse Violette*.

VEGETABLES.—These were very poor excepting Tomatoes, which were of prodigious size. The Beans looked like semi-dried specimens, and would not be tolerated in England, but it is the French custom to eat them partly ripe. Potatoes were numerous, staged, but lacked the smooth clean appearance of English-grown tubers.

A special feature of the Exhibition was an extensive assortment of specimen *Coniferae* lifted and plunged in groups out of doors; the shrubs were very healthy, and superior to those usually seen at English exhibitions. There were also several collections of fruit trees lifted and planted again in groups to illustrate the cordon, pyramid, and other systems of fruit culture. These, with a great variety of horticultural appliances, made an extensive and interesting outdoor display, amongst which the visitors could ramble and listen to the excellent band of over sixty performers of the Garde de Paris regiment.

Lady Dorothy Nevill sent some skeleton leaves of *Ficus religiosa*, grown and prepared at Dangstein; also various articles in oak wood, showing in place of the natural colour a green tint produced by a fungus (*Peziza aruginosa*), which were much admired, and for which a medal was awarded.

The site selected for the Exhibition was very suitable. The Show was a good one, enhanced as it was by the collections from England. The arrangement of the various groups was tastefully and admirably executed. Nearly all the pots throughout the Exhibition were buried in the soil, so that each separate collection had the appearance of growing in its fixed position. The visitors were very numerous notwithstanding the excessive heavy rains on the first day. But though the arrangement of the plants was admirable, we regret to say that the system, or want of system, for placing the prize cards was extremely faulty. The judging commenced between 9 and 10 A.M. on Saturday morning, and up to 3 P.M. on Sunday there was not a prize card nor scarcely a name of the grower affixed to the collections, consequently the great point of interest to the majority who visit horticultural exhibitions on the first day was comparatively lost. Our good friends would do well to adopt the system of the Royal Horticultural Society of England, and instead of placing an ugly stick in the front of each collection, with three cards affixed about 8 inches long and 2 wide, with a simple number on one, exhibitor on the second, and the number of the class on the third, they should simply place one card with the name and address of the exhibitor on one side, and the number and class on the reverse, and allow the judges to affix the awards; they would then confer a great boon on the public and the press, and would save an immense amount of time and trouble to the hard-worked executive. What should we say in England to an exhibition being open for thirty-six hours without being able to ascertain the name of the exhibitors or the winners of the prizes?

NOTES AND GLEANINGS.

THE thirty-ninth anniversary meeting of the ROYAL BOTANIC SOCIETY was held in the Gardens, Regent's Park, on Saturday, Mr. James Heywood, F.R.S., in the chair. The annual reports of the Council, Auditors, and Secretary were read. From these reports it appears that the affairs of the Society are in a satisfactory state; the receipts in each of the several items had exceeded those of 1877, the balance being some £600 better. The number of new Fellows elected was 112. Four hundred and eighty-one free students' orders for terms of two to six months each had been issued, including sixty-three to artists. The number of cut specimens given to students, professors, and teachers at the several medical and other schools was 63,414—an increase of 20,000 over last year, and 40,000 more than in 1871. The usual exchange of plants and seeds has been maintained with vigour; valuable contributions to the Society's collections were received from correspondents, including the Botanic Gardens of South Australia, Mauritius, Dublin, &c., and also from the Royal Gardens, Kew.

—A CORRESPONDENT who has recently visited Mr. Treseder's nursery at Cardiff states that the thousands of ROSES there are remarkable for strong, clean, luxuriant growth. Mr. Treseder seldom uses rooted Briars, but inserts cuttings, and in this way he not only finds them to root freely, but the roots are much superior to what are produced by the old club style of Briar root which is lifted from the hedgerows.

—THE EAST TOWER HAMLETS FLORICULTURAL SOCIETY held their fourteenth annual Flower Show on the 24th and 25th inst. This Society, Mr. Cole of Kensington Gardens, who was one of the Judges, informs us, is entirely local in its operations; it was founded and is sustained by a number of

working men who call themselves amateur florists, and in most cases the only leisure time they have to devote to flower culture is in early morning or late at night. The exhibition days are the only days that remunerative labour is given up for the plants; and agreeable must be the change to those lovers of flowers when they pass from the noisy dusty streets to tables and banks of choice and beautiful flowers. A Show provided under such circumstances proves what may be done by perseverance, and it affords encouragement to others to cultivate plants and beautify their homes with flowers. We are glad to learn that great success has attended the efforts of this useful Society, for the members are on the increase, and it has liberal support from the public of the district. The exhibitions improve every year, and that just held was a credit to all connected with it. Besides prizes offered and well competed for Fuchsias, Geraniums, Dahlias, Asters, &c., the Show was rendered additionally attractive by a valuable collection of plants from Victoria Park.

— CAPTAIN HANKEY informs us that there is to be seen in the garden of Mrs. Fuller, Rokefield, near Dorking, seven plants of *LILIUM AURATUM* of great size and beauty. No. 1 is 8 feet 6 inches high, and has sixty-four blooms on one stem, eight others on two other stems. No. 2 is 8 feet high, about twenty-six blooms coming. No. 3 is 7 feet 2 inches high. No. 4 is 7 feet high, eighteen blooms all out. No. 5 is 6 feet 6 inches high. No. 6 is 5 feet high, eleven blooms out. No. 7 is 5 feet high, eleven blooms coming. One bloom has petals 7 inches long.

— THE finest flowers, and one of the most beautiful displays of *NYMPHÆA DENTICULATA* that have come under our notice, are in the aquatic house in Sir Henry W. Peek's garden at Wimbledon. Seen towards the evening when dozens of large flowers are expanded the appearance of the tank is most attractive. Amongst other plants elevated above the water is perhaps the oldest plant in England of *Tabernaemontana coronaria*, the pot being quite hidden by a luxuriant mass of *Panicum variegatum*, which in this position, just above the water, has a charming effect. Overhead the profusion of golden blooms of *Allamandas* render this house additionally ornamental; but the *Nymphæas* have of late been the chief feature of the house.

— ADJOINING the aquatic house above referred to is a house devoted to BANANAS, and the growth the plants have made this year is altogether extraordinary. In the spring they were small plants about 2 feet high, and they now have stems nearer 3 feet than 2 in circumference. The foliage is majestic, and grand clusters of fruit are showing—clusters having ten or eleven whorls. The fruit will be ripe about Christmas, and if the plants do not receive any check we shall not be surprised if some of the clusters do not approach 100 lbs. in weight. As an instance of luxuriant tropical vegetation these sturdy and exuberant Bananas are worthy of mention and of inspection.

— MR. HENRY BOOTHBY, Holme Cottage, Louth, writes to us as follows about the FRUIT CROPS in the Fen district of Lincolnshire:—"Apples generally are a complete failure, Normanton Wonder, White Quarrenden, and Stamford Pippin (Laxton's), a fine kitchen Apple, and especially Golden Pippin, have been exceptions. Pears also are a greatly deficient crop, except some new varieties—notably the Hessel, which is bearing enormous crops. Several large-sized standards and bushes of Marie Louise and Louise Bonne of Jersey have been without a single fruit. Red, White, and Black Currants have yielded well; but not so the Gooseberry, which has been very deficient. There have been a few exceptions, and I herewith send a small branch of one of my seedlings, bearing this year for the first time, as a specimen of overloading. The small tree is crowded in every part. The American Blackberries, such as Lawton, Picaninny, and some others, are bearing abundant crops of more than usually fine large fruit."

— FORMERLY the LAVENDER PLANTATIONS of Surrey were confined to the parish of Mitcham, but of late years, to keep pace with requirements of the manufacturers, it has been found necessary to considerably extend the area, and plantations of vast extent are now to be met with in Beddington, Wallington, Sutton, and Carshalton, and it is computed that in this district there are at least three hundred acres under Lavender. It is now about eighteen years since the first plantations were formed in Beddington, and from thence the culture has extended to the adjoining parishes.

— IT may be well to remind those who are proposing

to grow GLOXINIAS FROM SEED that fine flowering plants are produced much earlier by sowing the seed now than by the usual custom of sowing in the spring. If the seedlings are potted in small pots and placed on a shelf close to the glass in a stove they continue growing steadily throughout the winter, and very early in spring are ready to be shifted into larger pots. By that mode of culture fine flowering plants in 5 and 6-inch pots are produced early in June. Seed sown in spring affords plants which yield a valuable succession of flowers later in the season.

CAPE HEATHS.—No. 8.

AUGUST.

ALL those having *Ericas* standing in the open should now endeavour to give them some protection from heavy and continual rains. More especially is this necessary where the plants are placed upon a wet or undrained bottom. Where shelter cannot be given in this temporary situation let them be removed to frames or to their winter quarters; the former is preferable.

Fig. 25.—*Erica infundibuliformis*.

where the accommodation can be given. Here they should have a cool bottom to stand upon, for we have frequently seen Heaths, more especially the softer-growing kinds, go quite blind (that is, lose all the flower) through being suddenly removed from a cool standing place to an open greenhouse stage. Wherever they are placed, however, all the air possible must be given. Look carefully to the watering; see that none are only half watered, as this is a fertile source of mildew. Should this pest put in appearance dust the plants affected with sulphur; use it carefully, because it does not improve the appearance of the plants, and the less waste the better.

Erica Uhria pilosa.—An extremely showy plant. Leaves arranged in threes, linear, and densely clothed with ciliated hairs, dark green. Flowers produced upon the apex of the small branches, mostly in couples; these are tubular and clavate, furnished with short hairs; colour deep reddish purple, green at the ends. Whole flower gummy.

E. nitida.—This is a perfect little gem, and should be more frequently found in amateurs' collections. Leaves obtuse, linear, spreading, arranged in threes and dark green. Flowers terminal, on short footstalks, in small umbels of three to six, globose, with a recurved limb, clear snow white.

E. metulaeflora bicolor (fig. 24, see p. 167).—A charming free-flowering variety, free from the pest mildew, which is such a plague to the old *metulaeflora*. Leaves arranged in fours, linear, smooth, and light green. Flowers in terminal umbels

of six to twelve, tubular, erect and oblong, soft rose colour, with a white neck and limb.

E. ornata.—This is a superb garden hybrid. Leaves arranged in fours, linear obtuse, hairy at the margins, and deep green. Flowers arranged in terminal whorls of six to twelve: they are large, tubular, with an inflated base, where the colour is soft rose or rosy carmine passing into white, and with a pale green band round the neck; segments of limb reflexed, white.

E. lateralis.—A slender-growing species, much branched. Leaves arranged in fours, linear obtuse, erect and dark green. Flowers globose, set upon long coloured footstalks, arranged in terminal umbels of six to twelve, and deep purple.

E. cubica minor.—A slender, dwarf, much-branched plant of great beauty. Branches arranged in whorls of three to five. Leaves linear obtuse, arranged in fours, shining dark green. Flowers in whorls near the ends of all the branches, bell-shaped, and deep reddish purple.

E. Aitoniana Turnbulli.—A slender-growing plant of great beauty. Leaves broadly linear, spreading, slightly recurved, dark green. Flowers an inch or more in length, in umbels of six to eight, tubular. Flowers white, changing to flesh colour or pink by exposure to the sun and air; segments of limb large and spreading, white.

E. infundibuliformis (fig. 25).—This is a dwarf-growing and very elegant species. Leaves arranged in fours, linear obtuse, smooth, erect, and dark green. Flowers in large terminal whorls upon all the branches; tubes long and slender, bright red; limb white; calyx imbricated, leafy.

E. effusa.—This together with *E. ornata* are garden hybrids which originated with the Messrs. Rollisson & Sons of Tooting, and they cannot be too highly recommended, for they are of good habit, large flowers, fine colours, very distinct and profuse bloomers. In this variety the leaves are dense, linear obtuse, dark green. Flowers produced in large terminal whorls of six to twelve, large, tubular, with an inflated base; colour wholly bright reddish crimson; segments of the limb reflexed, straw colour.

E. cerinthoides (fig. 26).—A strong and vigorous grower, although somewhat lax, and therefore requiring more support than many other kinds. Leaves in fours, linear oblong, acute, and profusely clothed with long light-coloured hairs; whorls terminal, many-flowered. Flowers tubular, with a slightly contracted neck, about an inch long, hairy, bright scarlet throughout. In the variety coronata the leaves are shorter and more erect, whilst the whorl of flowers is larger and spread evenly round, forming a corona or crown upon the ends of the shoots.

SUBTROPICAL BEDDING.

THE observations I propose making on this subject were suggested by a transient visit to the small but admirably arranged grounds and houses of W. D. Hemphill, Esq., M.D., Oakville House, Clonmel. Now that gardeners and others will be speculating on what they shall have in their beds and grounds next year good examples of garden decoration cannot be otherwise than appropriate.

Subtropical gardening I take to mean the substitution of bold striking foliage and beauty of form with diversity and brilliancy of colour during the summer months, for the unvarying regular lines and circles of Geraniums, Calceolarias, Verbenas, &c. At Oakville the entire effect is produced by foliage plants, and excellent it is. All love variety in garden embellishment, especially when the display is lasting. Foliage lasts longer than flowers as a general rule, and hence one great recommendation for subtropical plants where they can be used. It would evidently be useless to attempt to bed out tender fine-foliaged plants in an exposed situation and with a poor shallow soil. Given a well-sheltered aspect, deep rich soil, and superior taste, there can be little doubt that the following subtropical foliage plants will enhance the beauty of a garden. A trial has been given in many places in this locality to such plants as Caladiums, Cannas, Begonias, Aralias, Coleuses, Wigandias, Ricinuses, Nicotianas, New Zealand Dracænas, Acanthus, also Beets, Centaureas, Yuccas and Aloes, the numerous family of Solanums, Ornamental Gourds, Kales, &c. All have more or less bold, brilliant, and striking foliage, and some have pretty flowers too. That such plants can be well grown and effectively arranged on a small scale Oakville is an illustration. Arranged with taste in four corner beds, with due regard to height, colour, and effect, are Caladiums, Begonias, Cannas, Ricinuses, Nicotianas, Aralias, Yuccas, and several others. Artistically converging from a central foun-

tain are beds of many rare and novel plants. And here I should specially draw attention to the desirability of a fountain when at all practicable where subtropical bedding is resorted to. Its cooling and refreshing vapour can be readily realised.—W. J. M., Clonmel.

AMARYLLIS GROWING MADE EASY.

IN reply to a correspondent ("W. D. P.") who wants to know more on the above subject than is given at page 447 of your last volume, I have to say that I alluded to what are

Fig. 26.—*Erica cerinthoides* (see opposite).

popularly known to gardeners as Amaryllises—Hippeastrums I believe botanists call them. The plants named by your correspondent are mostly hardy and need no special culture beyond planting in a well-drained border, with the exception, perhaps, of the Guernsey Lily, and that I have never seen cultivated very successfully in this country. What are popularly called Amaryllises are generally grown in stoves part of the season and kept dry another part, all of which I tried to point out was wrong in principle.

The best guide as to the depth a bulb ought to be in the soil is the position it naturally assumes while remaining healthy after being left two or three years without being disturbed. I find that my bulbs are quite on the surface of the soil, rather more so than an Onion is. A bulb 15 inches in circumference (and I have several that size) is in an ordinary 9-inch pot, and measures 8 inches from the surface of the soil to the top of the neck where the leaves are visible. One 12 inches in circumference is in a 7-inch pot and measures 5 inches to the top of the neck; but the different varieties vary considerably in

their measurements, some being wide and flat and others comparatively long and thin. All, however, are alike in their disposition to get on the surface of the soil.

Drainage, of course, is very important with plants which have to remain a long time in one pot; but I never place a great deal of it at the bottom, preferring rather to use lumps of charcoal or something equally lasting mixed with the soil throughout.

The plants flower in a warm greenhouse in March and April, and may be had all through the winter from November with a little more heat, but they are not then so good as they are if allowed to come on more naturally and flower in the spring.

—WILLIAM TAYLOR.

ON THE CYCLAMEN.

[By S. JENNINGS, F.L.S. Read at a Meeting of the Royal Horticultural Society, and extracted from the last issue of the Society's Journal. The first portion of Mr. Jennings's paper appears on page 285, of vol. xxxiv.]

III. *C. VERNUM*.—As its name indicates, a spring-flowering species, in bloom during March and April. There is much controversy as to the identity of this plant, arising from mistakes, afterwards corrected, made by early authorities; so much so that in some catalogues a distinction is drawn between the true *vernum* and the *vernum* of Sweet, which, as I have already pointed out, is really *ibericum*, a winter-flowering species, and in support of this statement I quote Mr. Atkins. Writing to me, he says: "See 'Bot. Mag.' t. 1001, figured as *hederæfolium*; this is the true *vernum*, called *repandum* in the 'Flower Garden,' and various other names here and abroad. The name *repandum* does not appear to have been used before Sibthorp, who associated the plant he thus names with Clusius' *Cyclamen verno tempore florens*."

On the other hand, Colonel Trevor, Clarke, a botanist whose opinion is entitled to the utmost respect, writes thus to me:—"The plant that occupied the name of *vernum* for many years was scarcely distinguishable from *Coum*, except by the leaf. I think it was a pity to disturb *repandum*, which was already muddled up with the autumnal *hederæfolium*, whilst the latter was confused with the summer-flowering *europæum*."

The flowers of *C. vernum* are very fragrant, in colour bright rosy purple, less frequently light rose, rarely white. Leaves broad, angular, and deeply lobed; the upper surface bright green, shining, and broadly marbled with silvery bands. Corm smooth, dark yellow, the roots proceeding from the centre of the under side of tuber.

M. Tyerman remarks:—"This interesting species is quite distinct from any other. The leaves and flowers somewhat resemble those of *hederæfolium*, but the flowers are longer, more slender, and destitute of the teeth-like projections formed by the reflexed segments of the corolla." The flowers and leaves are produced at the same time. This species is a native of Greece and Italy.

[NOTE.—Since writing the above I have prosecuted my inquiries amongst the great *Cyclamen* growers on the Continent, who, while freely admitting the inaccurate nomenclature which holds amongst them, explain that it would be almost impossible to adopt the more strictly correct names, as the former are now so generally used that the utmost confusion would ensue on any attempt to effect a correction.

As regards *repandum*, however, it would seem that the weight of continental evidence is to the effect that the irregularity of the growth of the root and leaves from the corm noticed by me on page 79, together with an irregularity in the form of the segments of the corolla, are distinctive features of this species, which I am assured are constant. If this be so it would certainly justify specific distinction between *vernum* and *repandum*.]

IV. *C. EUROPÆUM*.—Figured in Sweet, p. 176. A summer-flowering species, blooming from June to September, or even later. In cultivation this plant is by no means a free bloomer, but it is valuable as one of the most delightfully scented of all the *Cyclamens*. It is very distinct both in form and habit, and there should be no great difficulty in recognising it. The flowers vary in colour from a pale pink to a deep carmine; the mouth of the corona is wide and slightly angular. Leaves orbicular or reniform, somewhat denticulate, marbled on the upper surface. The tubers are irregular in shape, and grow frequently to a great size; rough, dark in colour, compressed. Roots proceed mostly from the under surface, but more or less from all parts of the tuber.

In habit it differs from other *Cyclamens* in forming short

gouty stems, which produce leaves and flowers; these stems if cut and planted will again strike root and produce plants. The growing shoots for leaves and flowers have a way of stoling horizontally underground for some distance before seeking the surface and developing, a habit likewise of *hederæfolium*, so that in pots when the spring growth is commencing the plant assumes the appearance of a nest of shoots.

V. *C. HEDERÆFOLIUM*.—This is the autumn-flowering species, that to which I have before alluded as found growing wild in some woods in Kent; but its native home is on the mountains of Switzerland, as well as in Italy, Greece, the Ionian Isles, Algeria, and elsewhere. Under this species should be classed a few others which have been described under different specific names; they are, however, only geographical forms of the same species. *C. africanum* or *macrophyllum*, a large coarse-growing variety, and *C. græcum* or *latifolium* is another, so also is *C. neapolitanum*, and on the Continent this species is also known as *C. autumnale*.

There is considerable variety both in shape and hue of the foliage as in the colour of the flowers, the former being sometimes dark green and almost free from marbling, and at other times really beautiful with bright silvery bands and markings. In the leaf this species most nearly approaches *C. vernum*, with more or less prominent lobes. The flowers vary in colour from pure white to the deepest rose; the reflexed sections of the corolla display at each edge a tooth-like projection, giving to the corona of the flowers a peculiarly diadem-like appearance. The tubers are very large, sometimes as much as 12 inches in diameter, round, compressed, dark brown, very rough, the roots proceeding from all parts of the corm.

Regarding *C. hederæfolium* the Hon. and Rev. Mr. Boscauwen writes to me that he has had it planted in the open ground for the past fifteen years, where it flourishes, so that we may say it is quite hardy, having been unaffected by 20° to 30° of frost.

VI. *C. PERSICUM*.—Of this well-known species it is unnecessary for me to say very much; it is the *Cyclamen par excellence* for fragrance, colour, and display, and it is upon this plant that the cultivator has spent his most earnest devotion. The finest specimens grown come to Covent Garden Market, and so great is the demand that one firm alone sends out from fifteen thousand to twenty thousand plants annually; but in proportion as the flowers are improved in size it appears certain that they lose in fragrance, because in its natural condition *C. persicum* is so fragrant that a single plant of it in bloom will fill a large room with its scent.

Mr. Boscauwen writes to me:—"I have had *C. persicum* in the open air for five years or longer. The plants are some of them under slight shade, others exposed on a north bank; they are, when in a north aspect, evergreen. I send you leaves that are over a year old. When evergreen they do not blossom so well in winter. The frost does not seem to injure them: the blossom sent stood 10° of frost last week. I do not think since I have had *persicum* out we have had over 16° of frost; however there has been skating within a few yards of the bank where they were growing."

It is to this species that my remarks on the cultivation of the *Cyclamen* mostly apply, all other species being hardy, or at least half-hardy. There is one peculiarity which distinguishes *persicum* from all the other species of *Cyclamen*. In all the rest, as soon as the flower has been fertilised and the seed-pod formed the peduncle commences to assume a spiral form, and as the seed ripens it is thus carried as on a contracting corkscrew down to the ground, and eventually under the surface, where it may germinate. *Persicum* is an exception to this rule.

(To be continued.)

HARDY PERENNIALS.

I WISH to thank Mr. Taylor for the useful article on herbaceous plants which appeared in the Journal on pages 121-2. May I ask him to give us a list of plants which bloom in the first half of the year? I am commencing to grow these most interesting plants, and any hints I can get from your columns will be much valued. At present I have very few, only such well-known species as *Phlox*. I would ask him to give a list of all the best *Aquilegias*, *Campanulas*, *Hepaticas*, and, above all, *Delphiniums*. I intend to purchase the varieties he names, and I shall be glad if anyone who knows the value of these plants will give me an idea of the cost of forming such a collection.

I have no catalogues of any herbaceous plant-growers, and so am a little at a loss as to the expense. I do not want any

alpines at present, only herbaceous perennials.—JOHN B. M. CAMM, *Charmouth*.

{The following are amongst the best hardy perennials flowering during the first half of the year. The prices range from 6d. to 3s. 6d., and would probably average 1s. to 1s. 3d. all through.

Anemone apennina
A. stellata fulgens
Anthericum granifolium
A. Liliago
A. Liliastrium
Aquilegia chrysantha
A. cærulea
A. cærulea alba
A. Witmanniana
Campanula carpathica alba
C. pulia
C. pumila alba
C. turbinata
C. turbinata albidia
C. Van Houttei
Centranthus ruber
C. ruber alba
Cheiranthus alpinus
Convolvulus mauritanicus
Delphinium Agamemnon
D. alopecuroides
D. atro-vioacea
D. azureum plenum
D. Barlowi perfectum
D. Belladonna
D. Felix Poulet
D. cardinale
D. cashmerianum
D. conspicua
D. Emperor of Prussia
D. formosum
D. formosum celestinum
Dielytra spectabilis
D. spectabilis alba
Erythronium giganteum
Gentiana acaulis
G. alpina
G. asclepiadea
G. bavaria

Gentiana gelida
G. verna
Hemerocallis flava
H. graminea
H. japonica
Hepatica angulosa
H. triloba alba
H. triloba cærulea plena
H. triloba rubra fl.-pl.
Iberis corifolia
I. gibraltaria
Iris iberica
I. susiana
Linum flavum
Lithospermum prostratum
Lychnis chalcidonica fl.-pl.
L. chalcidonica alba fl.-pl.
L. Haageana
Michauxia campanuloides
Mimulus moschatius Harrisoni
Myosotis palustris semperflores
M. dissitiflora
Nierembergia rivularis
Oenothera macrocarpa
G. riparia
Paeonia anemonæiflora
Papaver alpinum
P. bracteatum
P. orientale
Primula cortusoides amœna
P. cortusoides amœna alba
P. japonica
Spiraea aruncus
S. japonica
S. palmata
S. Filipendula flore-pleno
S. venusta
Viola cucullata
V. pedata

—WILLIAM TAYLOR.]

CHOICE GARDEN ORCHIDS.—No. 3.

ÆRIDEES, Lour.

(Continued from page 486, Vol. XXXIV.)

Ærides Houlletianum, Rehb. filis. Syn., *A. Mendellii*, Hort.—This rare species in habit of growth appears to be intermediate between *A. virens* and *A. falcatum*. Leaves strap-shaped, slightly recurved, tightly clasping the stem at the base, 6 to 7 inches long, light shining green in colour. Racemes simple, pendant. Flowers resembling in shape those of *A. falcatum*. Sepals and petals buff, shading towards the base into creamy white. Lip large, deep purple in front, white towards the base. Summer months. Cochinchina. 1868.

A. nobile, Hort. (Warn. Select Orchid. 1st Series, t. 11).—A very handsome species, by some considered a form only of *A. suavisimum*; it differs, however, in the three lobes of the labellum being nearly or quite equal in length, and the middle lobe being very slightly bifid. Leaves ligulate, obliquely emarginate at the apex; colour pale green, with darker dots both on leaves and stem. Raceme 2 to 3 feet long, branched, many-flowered. Flowers very fragrant. Sepals and petals spreading widely, white suffused with rose. Lip three-lobed; the side lobes large, creamy yellow; middle lobe tongue-shaped, slightly bifid, with entire margins, white, freckled with rosy purple. Spur conical, incurved, yellow dotted with red. June to August. Java.

A. crassifolium, Rehb. filis.—This extremely rare species has only flowered a few times in this country, but it lays claim to rank amongst the very finest in the genus. It is a dwarf dense-habited plant. Leaves closely imbricating at the base, lorate, obliquely bilobed at the apex, coriaceous in texture, dark green, freckled with purple dots. Raceme pendant, longer than the leaves, many-flowered. Sepals and petals oblong obtuse, deep pink, white towards the base. Lip large and spreading, deep pink. May and June. Moulmein. 1872.

A. Lobbii.—A fine species, of which we, however, have failed to find any figure to refer to. Leaves closely imbricating, lorate, obtusely bilobed at the apex, some 8 to 10 inches or more long, and bright green. Raceme pendant, very much longer than the leaves, frequently branched, many-flowered. Sepals and petals about equal, oblong obtuse, white suffused with rosy pink. Lip spreading, acute, rosy pink and white with frequent spots. June and July. Moulmein.

A. Lobbii, Hort.; var. *Ainsworthii*, Hort.—This variety is

probably represented in this country by only one plant, and therefore unique. It is a grand form, in which the raceme is wonderfully developed and the flowers wholly rich purplish crimson. June and July. Moulmein. 1818.

WEEDS.

A CORRESPONDENT, "A. B.," requires to know the best way of getting rid of weeds, and for answer one might naturally reply, "Chop them up." But this is a matter of such importance in the economy of a garden that I cannot lose this opportunity of drawing more particular attention to it.

Weeds are a source of vexation for many reasons. They entail a positive loss by exhausting the supplies of nutritious matter stored up in the soil for the benefit of the legitimate crops; they are offensive to the eye, and above all—and this is my point—the larger they grow the more loss do they entail and the more difficult are they to eradicate. Taken in their infancy as they first spring from the soil hundreds of them may be destroyed every time a light sharp hoe is drawn over the surface, and in a brief half hour as much work is done, and done, too, to far better purpose, than could subsequently be effected under several hours. Frequent surface-dressings, moreover, are highly beneficial to growing crops; it is a well-known fact that the metropolitan market gardeners find it profitable to have the surface often stirred with hoes among growing crops, which are thus brought earlier to maturity than when left alone with soil drawn up to the stems after the ordinary fashion.

There is no saving, no economy, in leaving weeds to grow at random for a month or two and then taking on extra labourers to clear them away, for then heavy hoes are required and they must be wielded with considerable power. Nor can the weeds be left to die, most large weeds retaining sufficient vitality after they are chopped up to start again into growth after the first shower, so there is nothing for it but raking them off and wheeling them in barrows to the rubbish heap, all which work is a great waste of time and money. Let me therefore advise "A. B." and every reader of the Journal to keep the size of their gardens well within the scope of their means, so as to be able to keep down the weeds; and, by affording an ample supply of labour power to thoroughly cultivate the soil, secure crops more abundant and finer than ever can be had under the wasteful method that is now much too prevalent.—EDWARD LUCKHURST.

NATURAL PRODUCTIONS OF CYPRUS.

A CORRESPONDENT has forwarded us the following remarks on Cyprus, taken from Franz von Löher and Mrs. A. B. Joyner:

"The principal productions are cotton, hemp, silk, corn, opium, tobacco, turpentine, liquorice, madder, several dye woods, gum tragacanth, and colocynth. Fruits of all kinds, in particular Grapes, Oranges, Lemons, Pomegranates, Olives, Walnuts, Figs, Mulberries, Apricots, &c.; the Carob Tree (*Ceratonia siliqua*) abounds in some districts. There were once extensive plantations of Sugar-cane. Large quantities of fine vegetables are grown. Cyprus was celebrated for Roses; Hyacinths, Anemones, Ranunculuses, Narcissus, Poppies, &c., grow wild. Trees and shrubs of all kinds grow luxuriantly, including Pines, Firs, Cypressess, Ashes, Oaks, Beeches, Elms, Myrtles, evergreens, Oleanders, &c. One of the most important plants of the island is *Ferula græca*, of the stalks of which the Cypriotes form a great part of their household furniture, and the pith is used instead of tinder for conveying fire from one place to another.

"The peasantry distil rose, orange, and lavender waters, myrtle and ladanum oil.

"Climate.—The climate is generally healthy, excepting on some parts of the coast, but this is entirely due to the neglected state of the country; if the much-needed drainage was properly carried out the most satisfactory result would ensue. As in most eastern countries, the rain falls at stated periods, commencing about the middle of October and continuing until the end of April, with the exception of February, which is often quite dry; after June slight showers fall from time to time, but have little power to modify the heat, which is, however, tempered occasionally by a cool wind. In September the great heat sets in, but does not continue for any length of time. The climate is, of course, cooler in the more mountainous portion of the west than in the flat eastern side.

"General Cesnola lived ten years in the island; his summer

residence was in the village of Dali, about halfway between Nitrosia and Larnaka, a small white cottage in a grove of Orange and Lemon trees. 'This simple abode became our summer resort for several years. It was surrounded by about six acres of ground laid out in alleys of Lemon and Orange trees and the favourite Caistrà, a delicious species of Nectarine. Two noble Walnut trees overshadowed the traditional alakah (the oriental or common well), and extended their shade to our out-of-door saloon, where we sat the day long reading, writing, and chatting, with the grateful breeze at all hours coming through the long verdant alleys hung with luscious fruit. A small rivulet of the purest water found its way from cold sources to the feet of these Walnuts trees, the broad leafy branches of which formed the ceiling of our drawing-room, and being blocked by a pile of rough stones, and tumbled, cascade fashion, into a basin scooped out to receive it, which served as our wine-cooler and refrigerator. We soon adopted the housekeeping system of the peasants and hung our plate baskets and table linen among the trees, and spreading out the thick mats of the country, with a wooden settle dining-table, where our Turkish attendants served us with as much attention as if at a state dinner, though not with quite the same ceremony. A little further on a few Turkish rugs and divans formed the reception room of state for the notables of Dali, consisting of an old cadi, an illiterate Greek priest, and three wealthy Turks of Potamia, who inhabit what was once a royal palace and the summer residence of the Lusignan queens.'" I wish I dare write what he says further of the charms of this beautiful island, but I must not trespass on your time longer.—S. S.

BOSCobel.

UNDER the above title we have received a pamphlet by Rev. Henry G. de Bunsen, M.A., Rector of Donington, and published by Simpkin, Marshall, & Co., London, which gives a full account of the Royal Oak, Boscobel House, and Whiteladies. To all who are interested in this historical old place we commend the pamphlet as being highly entertaining, as the following extract will show:—

"Boscobel House is the same house, and very much in the same condition, as when King Charles II. visited it and took refuge there on September 6th, 1651, after the battle of Worcester. It would appear that this house was built for the express purpose of hiding so-called 'recusants'—that is, those who, being Roman Catholics, refused to take the oath of supremacy. Hence the different hiding places where priests and others who were members of the Church of Rome could find an asylum from persecution, and worship God after their own fashion; for there was an 'oratory' in this house. There hangs over the chimney-piece of the dining-room an excellent portrait of Charles II.

"Adjoining the dining-room there is a small inner room. Upstairs, on the first floor, there are two contiguous bedrooms. A secret door in the wainscoting of the first bedroom opens into the large chimney stack which runs up from the bottom of the house to the top. Through this door you enter into a recess or closet having a trap door in the floor, by means of which formerly people could descend to the bottom of the chimney stack, where there is a door opening into the garden. It was through this perpendicular passage that Charles could pass unobserved from the garden into the house and to his hole, or escape from the house through the garden to the adjoining wood. In this room, just above the staircase and close to the window, there is a loose piece of board in the floor, and by lifting up this the hole (3½ feet by 4½ feet wide and 5 feet 2 inches deep) may be seen in which the king, it is said, passed one night in hiding. A short ladder gives the visitor an opportunity of going down into it, and enables him to realise in the total darkness of that small place what the king's feelings must have been during the twelve or more hours which he spent there in that dark and narrow space.

"THE ROYAL OAK.—Not far from the garden, in the field adjoining it, stands the Oak tree which is shown as the Royal Oak, surrounded by a substantial iron palisading. Whether this is the identical Oak in which Charles II. took refuge during his stay at Boscobel or whether it is another tree, which, when the 'poor remains of the Royal Oak (as Mr. Plaxton says), were fenced in by a handsome brick wall at the charge of Basil Fitzherbert, Esq.,' stood by its side, or has sprung up since within the same enclosed space, is one of the disputed points of the present day; for by some authorities the present tree is said to be between 400 and 500 years old, by others only 160 or 170 years. The author of the pamphlet gives all the authorities he has been able to collect, which seem to point to the present tree as not being the Oak in which Charles II. took refuge, and then gives the account of a living witness, in whose family the tradition has been handed down from father to son, that the present tree is the identical

Royal Oak in which Charles II. was hidden for a time. This later testimony is from the present Earl of Bradford, whose estate, Weston Park, adjoins the Boscobel property. His lordship's account, which is dated 'Weston Park, May 6th, 1878,' is as follows: 'The account I have been accustomed to hear all my early life from my father about the Boscobel Oak is that after the king had been for some days confined to the house at Boscobel they could not dissuade him from going out to get fresh air, or even from going sometimes further from the house than was prudent. On one occasion, when he was out with one or two of the Penderils, sounds were heard of horses' feet not very far off. There was not much time for consideration, but his attendants thought he might not be able to get back to his hiding place in the house quietly, or perhaps thought that even if he did he might be discovered there, and recommended him to go into a thick part of the wood (it was early in September and the trees and underwood still in full leaf), where they helped him up into an Oak tree (not a decayed but a growing Oak tree), and implored him on no account to come down from the tree until they should return to him and tell him all was safe; they then went as if to their work or ordinary occupation. The troopers of the Parliament fell in with them, made all sorts of inquiries about the house, and its inmates, and its neighbourhood, and ultimately rode on without discovering how near they were to the king. The Penderils returned in due time and conducted the king back to the house.

"The tree was from that time well known to them and doubtless to the owner, Mr. Giffard, and other loyal friends in the immediate neighbourhood; and after the Restoration, which was only nine years afterwards, probably numbers of people visited the tree, although at that time in a thick coppice with only woodman's paths or very bad cut roads in the neighbourhood. The coppice was subsequently cleared, I apprehend in the time of the Fitzherberts, who inherited from the Giffards, but the tree into which the king climbed was left standing, and regarded with pride and affection. It has been known from father to son by succeeding generations from that time to this. As to its being a substitute of any sort, least of all an acorn from the original tree, I discard the idea as ludicrous and absurd. I have known the tree myself for half a century; it looks now very much as it did then; and nearly as long ago as that I remember my father speaking of the absurdity of the stories then current as to the owl flying out of the decayed tree, the present tree being an acorn from the old one, and such like. He used to say that he had heard his father and, I think, his grandfather, speak in the same sense, and the recollection of the tree by his grandfather, my great-grandfather, would easily carry him back as far as 1740, which would be less than ninety years after the king sat in the tree.

"I may mention with respect to Oak trees and Oak wood in this neighbourhood, that there are trees still alive in this park estimated to be 1100 or 1200 years old; there are others reckoned to be 600, 500, and 400 years old. Sometimes a smaller tree is known to be considerably older than a larger one, and I should myself estimate the tree at Boscobel to be 400 or 450 years old; but it would have been equally capable of affording a hiding place for a man, in the middle of a thick wood, whether it was then some 220 years old, as I estimate it, or whether it were 100 years younger or older.

"I further remember my father speaking of hearing from those who went before him that some of the labouring men on the estate had pointed out the tree from father to son as the tree which the hander-down of the tradition himself remembered as the Royal Oak. It is mentioned in some of the histories and guide books that great quantities of branches and pieces of the Royal Oak had been from time to time broken off and carried away by visitors. Now it so happens that the appearance of the tree at present looks exactly as if a great many of the lower branches had been broken or cut off, and no doubt they were; but it must be remembered that visitors were comparatively few before the days of railways, excursion trains, and cheap guide books, and that since these things were invented, and indeed before, the tree has been protected by a wall, and later by a high railing."

WORK FOR THE WEEK.

KITCHEN GARDEN.

PULL the main crop of Onion as soon as ready, and have them thoroughly dried before storing them away, freeing the bulbs of roots and adhering soil, but do not peel them, as is too frequently the case, or they will not keep sound and heavy. The ground upon which the Onions have been grown will be available for early Cabbages, which as a spring crop is one of the most important, indeed it is the most generally valued of spring and early summer vegetables. The ground should be well and deeply dug; if in good heart from recent manuring none need be applied, and in very light soils forking over the surface will be sufficient, as in such soils the Cabbages go much to leaf, and do not produce hearts so early, nor withstand the weather so well, as those in firm soil. We like to

give the ground before planting a dressing of salt, lime, soot, and wood ashes—half a peck of salt, half a bushel of lime, half a peck of soot, and a peck of wood ashes—which may be applied to 30½ square yards in the quantity named. The plants should be kept free of grubs, caterpillars, slugs, &c., by dusting them with quicklime or dry wood ashes, and they should be planted before they become gross and leggy, planting them 18 to 20 inches apart, as they will not be allowed to stand long after coming in. Plantations of Globe Artichokes should be gone over and have all useless stems cut away and any decayed leaves removed, so as to admit light and air to the base of the crowns. Remove the leaves from over the clusters of Tomatoes, and keep the shoots well stopped so as to aid the swelling of the fruit, watering well in dry weather. The fruit when it changes colour may be placed in a house or upon slates in a frame or pit to ripen, where it will do so perfectly.

FRUIT HOUSES.

Figs.—In Fig houses the trees not unfrequently grow rampantly, and consequently produce thin crops of fruit. In that case root-pruning may be resorted to, and the roots be confined to a border of from 3 to 4 feet in width. If the drainage be defective it will be necessary to lift the trees in the autumn so soon as the leaves commence falling and replant in fresh soil. Place 9 to 12 inches of rough stones or brickbats for drainage, and over it a covering of rather rough lime rubbish, using the finer parts for mixing with the compost in the proportion of a tenth to turfy loam, and a twentieth of crushed or half-inch bones, and in replanting ram the soil well about the roots, for short-jointed fruitful wood cannot so well be secured by any other means than by a solidified compost. The border should be 30 inches deep. Should the drainage be good it will only be necessary to confine the roots to the narrow border and removing some of the old soil from amongst them, top-dressing with turfy loam with an admixture of lime rubbish and crushed bones as above stated. See that those in pots placed outdoors do not root from the base of the pots; cut off all such roots, top-dress with decayed manure or rich loam with a sprinkling of crushed bones, and afford a good watering, after which afford no more than to keep the foliage fresh.

Pines.—Suckers obtained from the summer-fruiting plants will soon be ready to repot. It is well to divide the plants into two batches; one, the strongest, should be shifted into their fruiting pots as soon as ready, employing 10-inch or 11-inch pots according to kind, affording them a position near the glass in a light airy house, keeping them gradually growing on through the winter. The plants so treated will be readily excited into fruit next May or June, and will afford a good supply in late summer or early autumn. The other plants, suckers from the summer fruiters, not large enough to shift into fruiting pots, winter in the 7 or 8-inch pots, transferring them to the fruiting pots as soon as ready in the spring, which with suckers of Smooth-leaved Cayenne that were started last March will provide a successional supply of fruit through the winter months. A re-arrangement of the plants should now be made in order to separate the fruiting from the non-fruiting plants, as many of those that were started from suckers of last summer's fruiters will have fruit swelling off. Those plants not fruiting will have completed the growth, and should have air very liberally for the next six weeks when the temperature exceeds 80°, maintaining the bottom heat steady at 80°; and all plants well established—i.e., well rooted, should have a bottom heat of 80° to 85°, but recently potted plants, or those not having roots well established in the fresh compost, maintain at 90°. Plants swelling off the fruit should have moderate atmospheric moisture, admitting air just a little at the top of the house early in the morning, so as to allow of any superfluous moisture escaping before the sun's rays act powerfully or directly upon the fruit. Any fruit it is desired to retard should be moved to a rather cool or shady house, affording an abundance of air.

Melons.—In pits and frames the last batch of plants will have set or be setting the fruit. Ours are well set, the atmosphere having been kept dry, and are swelling away freely. We now sprinkle the plants with tepid water and close early in the afternoon at 80°, admitting air at 75°, increasing with the advanced sun heat to 85° or 90°. Those in frames should be attended to as required with linings of sweetened fermenting material as the nights become cold, so as to prevent the temperature falling below 65° in the morning; and if mats are placed over the lights after the sun leaves the frames, and removed shortly after the sun has risen, very much greater success will be had with late Melons than usually results from frames. Maintain a night temperature of 70° to 65° at night and 75° by day in Melon houses heated by hot water. As the days are shorter lessened supplies of water will be required; yet give sufficient to keep the soil in a moist state whilst the fruit is swelling, but after it is full-sized or ceases swelling afford no more than to maintain the foliage from flagging. Keep the laterals well stopped to one leaf and rub off superfluous shoots as they show, allowing nothing to interfere with the principal leaves or to retard the swelling of the fruit. Plants with fruit advanced for ripening should be kept dry at the roots and have air very liberally, with, if practicable, an advance of temperature, avoiding a close moist atmosphere, which invariably results

in cracking of the fruit or inferior flavour. The last batch of plants will have been planted in houses and will be growing freely. The leader must not be stopped until it reaches the trellis, when it may be pinched out if more than one leader is wanted, or may be allowed to grow two-thirds of the distance up the trellis if only one leader is wanted and then be stopped, removing every alternate lateral directly they can be handled. Maintain a moist and warm atmosphere—70° to 75° by artificial means, with the bottom heat at 80° to 85°. Keep a sharp look-out for canker at the collar and upon the stem, rubbing quicklime well into the parts affected, striving to maintain a clean growth and healthy collars to the last.

Cucumbers.—The autumn fruit should be encouraged to make a strong growth by earthing-up betimes, affording plenty of water at the roots, and in the atmosphere during bright weather, syringing at 3 to 3.30 P.M., damping two or three times a day, closing at 80°. Maintain a temperature of 70° to 75° from fire heat, and attend well to thinning the shoots and training. There must be no want of attention to thinning-out old growths in fruiting plants, training and stopping, and the removal of bad leaves. Plants in frames that have fruited for some time will be restored to vigour by a good thinning-out of the old shoots, and the addition of a little fresh loam as a top-dressing, laying some of the young growths in the loam, giving a moderate watering, and a sprinkling overhead on bright afternoons, closing at about 3 P.M. With linings and the protection of mats over the lights Cucumbers will be produced for a lengthened period. Houses that are intended to be used for a supply of fruit at Christmas should be cleared with dispatch, so that the needful cleaning, repairs, or painting may be done thoroughly before the house is wanted.

PLANT HOUSES.

Stove.—*Clerodendron fallax* is one of the brightest of stove plants, and is best raised from seed, which will now be ripe, and should be sown at once in small pots, the plants not transplanting well. Place the pots in a shady part of the stove until the seedlings appear, when they should be put on a shelf near the glass, shifting into 6-inch pots when they have made a pair of leaves. They must be kept near the glass, and in spring shifted into 8 or 10-inch pots. They thrive well in turfy loam with a fourth of leaf soil and a free admixture of sand. Old plants which have ceased blooming may have the shoots shortened back a little, which will induce some growth, but before winter they must be headed-back rather closely. If kept warm and damped with the syringe every evening they will soon break, when they may be turned out of the pots, the ball being partially reduced, and potted in smaller pots for the winter. *Luculia gratissima* is not a stove plant and not exactly a greenhouse plant, but it does best in an intermediate house or a cool stove. The plants should now be afforded plenty of light, and be kept rather cool and well ventilated so as to induce flowering, for if kept moist and warm they will continue growing. Too much water must not be given at the root, and by subjecting a portion of the plants only to this treatment at present, and a batch later on, a succession of bloom will be obtained. *Amaryllises* will now be fast completing their growth and should have a lessened supply of water, but avoid anything like a parching dryness at the roots. The evergreen kinds, of which there are too few, must have sufficient water to keep the foliage fresh, and be placed in a light airy situation in a cool stove to solidify their growth. Winter-flowering *Begonias* must not suffer by want of pot room, yet afford sufficient soil to secure a good growth with healthy foliage, assisting plants that are required to flower in small pots with weak liquid manure frequently. *Euphorbias* that have been placed some time in cooler quarters must not remain too long or the roots will suffer, particularly if the watering be excessive, in which case they will be of little value. They should have a house or pit with plenty of air and all the light practicable. *Poinsettias* should not be kept too long in frames or pits, or they will when moved to warmer and drier quarters lose the lower leaves. They with the *Euphorbias* should have a night temperature of about 55°. *Ixoras* that have been employed in conservatory decoration must be returned to the stove—placed in the warmest part, cutting off all their old flowers. *Medinilla magnifica* should now be kept rather drier and have a light airy situation, ceasing to syringe overhead. *Clerodendron Balfouri* and *Bougainvillea glabra* which have been for a time in cooler quarters must be returned to the stove, but the coolest and most airy part should be selected, and water should be gradually withheld, yet not so as to destroy the foliage prematurely. *Æschynanthuses* coming into flower must be well attended to with water, especially those grown in baskets, or the flowers will be of short continuance. Any varieties of *Gloxinias* it is desired to increase should have the leaves inserted four or more around the sides of a 6-inch pot well drained and filled with sandy loam and peat, with half an inch of sand upon the surface. Any scarce sorts may have the leaf laid flat on the surface, previously severing the midrib three parts through on the under side, placing a pebble on the upper side of the leaf over each incision. See that the plants that have ceased flowering are not dried off too quickly, but are afforded light, air, and the requisite

warmth until the growth is completed. Similar remarks apply to Achimenes.

TRADE CATALOGUES RECEIVED.

William Paul & Son, Waltham Cross, London, N.—*Catalogue of Bulbs, Camellias, &c.*

T. Bunyard & Sons, Maidstone, Kent.—*Select List of Hyacinths and other Bulbs.*

TO CORRESPONDENTS.

* * All correspondence should be directed either to "The Editors" or to "The Publisher." Letters addressed to Mr. Johnson or Dr. Hogg often remain unopened unavoidably. We request that no one will write privately to any of our correspondents, as doing so subjects them to unjustifiable trouble and expense. Correspondents should not mix up on the same sheet questions relating to Gardening and those on Poultry and Bee subjects, and should never send more than two or three questions at once. All articles intended for insertion should be written on one side of the paper only. We cannot reply to questions through the post.

REFERENCES (J. S.).—The writings to which you refer are scattered over a long period. See page 158, vol. xxix., and page 398, vol. xxxii., as examples of what you require.

CARPET BEDS IN BATTERSEA PARK (J. T., *Huntingdon*).—We have seen the beds to which you refer, and have admired their chasteness and general high finish. Your suggestion shall have our attention.

GRAPES SHANKED (A *Young Gardener*).—The shoulder of Tróvén Frontignan is seriously shanked, the leaf of Mrs. Pince much scorched, and the berries, what few of them that have set, spotted. In all probability the roots of the Vines are in a bad state, owing either to stagnant or otherwise unsuitable soil; and we also think that you have kept the house too close and moist, and the temperature generally too low, the Tróvén Frontignan thriving best in what is known as Muscat heat. You cannot arrest the decay of the present crop, but you may improve the condition of the Vines and have better results in future years. Presuming that the viney is heated we advise you to keep up a minimum night temperature of 65° with a proportionate rise during the day, giving also abundance of air, and not entirely closing the house at night. This will accelerate the ripening of the Grapes and promote the maturation of the wood. As soon as the crop is cut we should renovate the border by first draining it well and then removing a good portion of the old soil, which is probably sour, and applying fresh soil to the roots. The best soil is turfy loam, but it is not always procurable, and it is well to remember that good Grapes can be grown in ordinary garden soil, provided it is well drained and in a fertile state. If crushed bones, a bushel to each cartload, or wood ashes, or charred vegetable refuse, also a little soot, can be mixed with the soil they will greatly improve it. Raise as many of the roots of the Vines as you can without injury, and cover them 4 or 5 inches deep, placing a heavy top-dressing of rich manure on the surface of the border. If you can do this quickly while the foliage is still green you can induce the formation of fresh roots before winter, especially if you keep the house warm, close, and moist, so as to preserve the foliage as long as possible. If you cannot renovate the border early in the autumn you may do it in fine weather after the Vines have been pruned. First secure healthy root-action, and then carry out the instructions as to temperature, ventilation, &c., that are given in "Work for the Week," and you will succeed in your attempts to grow good Grapes.

FREED POTTING SOIL OF WORMS (K. T.).—The most certain method is to subject it to heat—char it lightly over a good fire or heat it upon iron plates over a fire, but not so highly as to burn it; or the compost some time before it is used for potting may be turned over in layers of about 3 inches thick, sprinkling each layer with soot in the proportion of about a twentieth of that of the compost, and turning it over in about a week. Lime water may also be applied, which will drive the worms from the compost. A peck of lime to thirty gallons of water, stirred well up, allowing to stand forty-eight hours, and then saturating the soil with the clear lime water. The soil will require to be placed in a shed to dry some time before use, as it does not answer to pot plants in wet soil.

AMARYLLIS TREATMENT (W. M.).—They should be moved to a light airy situation in the stove, keeping them moderately supplied with water. See notes in this week's "Work." They will flower next spring or early summer provided the growths be well matured. Turfy loam with a fifth of well-decayed manure will grow them well, good drainage being afforded.

WINTERING ALLAMANDAS, CLERODENDRONS, AND BOUGAINVILLEAS (Idem).—They are deciduous, losing their leaves in winter, and should now have the supplies of water gradually lessened, and when the leaves fall afford no more than to keep the wood plump. Prune in February, removing the weak wood, cutting the Allamandas and Bougainvilleas back to two joints if the plants are as large as desired, or shortening the strong shoots so as to induce shoots for the covering of the trellis. The Clerodendrons must not have more than the weak shoots thinned, and any of the unripe points of the long last-year growths shortened to firm wood. Turfy loam, with a fifth part of well-decayed manure, will grow them perfectly.

PRUNING PASSIFLORAS (Idem).—Prune them in spring or before they commence growth, cutting back the side shoots to within two or three joints of their base, and any shoots required for extension should be cut back to firm well-ripened wood. The flowers are produced upon the current shoots, some few producing cymes of flowers from the old wood, as P. princeps and P. Madonna.

CLIMBERS FOR GREENHOUSE (An *Old Subscriber*).—We presume you require them for the roof or rafters. Habrothamnus fascicularis, Jasminum grandiflorum, Kennedyia inophylla floribunda, Passiflora Imperatrice Eugénie, Tecoma jasminoides splendens, Tacsonia insignis, Rose Maréchal Niel, Clematis Lucie Lemoine, Lapageria rosea, Rhynchospermum jasminoides, Plumbago capensis, Mandevilla suaveolens. Those marked with a star are the most suitable for roofs, the others for pillars or short rafters.

SELECT PHLOXES (J. Pearson).—The following will probably suit you,

but to do well they require liberal treatment:—Jessie Laird, D. P. Laird, Croix d'Honneur, Souvenir de Berryer, Mrs. Balfour, William Blair, Madame Marie Saison, Roi des Roses, Mons. Hock, Madame Ladonette, Lamartine, and Lothair.

LILIUM AURATUM NOT EXPANDING (F. W.).—We do not think the slight shade from the Pear tree will account for the buds not opening, but should attribute it either to the drought at the early part of August, which, for want of a surface dressing, destroyed the stem roots; or the poisons of cow dung, one-third to two-thirds water, having caused the roots to decay. The fungus on the Elm stump is Sphaeria mammillaris.

CLEMATIS JACKMANNI MILDEWEED (Idem).—This is a result of the late drought—dryness at the roots. Water copiously at the roots in dry weather and overhead before flowering, dusting with flowers of sulphur for the destruction of the mildew. Clematises are not particularly subject to fungoid attacks.

MARECHAL NIEL ROSE NOT THRIVING (J. V. U.).—The Rose planted in March and allowed to flower freely the same season has become exhausted. It ought to have been cut back for the purpose of encouraging the growth of young wood. Keep the plant healthy by watering it as required and syringing, and early in the spring prune it rather severely, and you will probably obtain healthy growth.

WASPS EATING GRAPES (C. J. W.).—Stretch the hexagon netting made by Haythorn of Nottingham over the openings of your ventilators, and so exclude the wasps from the Grapes. You may obtain the netting direct from the maker or through any nurseryman.

PROTECTING PEARS FROM WASPS AND FLIES (E.).—There are two ways in which this can be thoroughly done—either erect a light framework of timber over the pyramidal trees and stretch some of Haythorn's hexagon netting over it, or tie a loose bag of gauze over each fruit. The netting is altogether preferable, because you can more readily watch the progress of the fruit. We consider this the best of all garden netting, excluding as it does insects as well as birds from fruit, and it is very durable, lasting nine or ten years with care.

TRANSPLANTING PYRAMIDAL FRUIT TREES (Idem).—They may be removed as early as September, removing their leaves at the same time, but, of course, you would not touch the roots of a tree till its crop of fruit was gathered, and some sorts require to hang much longer than that.

VARIOUS (Idem).—Cherries for a succession are Early Purple Glean, May Duke, Governor Wood, Elton, Kentish, and Morello. The best red Raspberry is Prince of Wales, and the white so called is Yellow Antwerp. The goodness of Asparagus depends solely upon culture. Procure strong roots of the sort common to gardens, such as respectable nurserymen supply, afford it high culture, and you will have what you require. The Ivy, if kept within moderate bounds, will not injure the Elm tree.

TECOMA RADICANS MAJOR NOT FLOWERING (A. B.).—Encourage the formation of stout shoots by a judicious system of pinching and pruning. Keep the shoots well apart, so as to admit plenty of light and air among them. Let your plant have ample space to ramble, and you will in due course be rewarded with rich bold flower clusters. The most flowers we ever saw of this upon a single plant were obtained by letting the growth run wild along the top of a wall.

ROSES MILDEWEED (Idem).—Encourage new strong growths by giving liquid manure to the roots plentifully and scatter flowers of sulphur upon the affected foliage, renewing it again and again if washed off by rain before a cure is effected. The malformation of the flowers is, we think, an indication of debility. Well shorten and thin the wood at the time of pruning, and apply a heavy dressing of rich manure to the soil as soon as possible.

MATRING GLOXINIAS (A. A. M.).—Place the plants on the shelf of a cool stove or warm greenhouse, and water them just sufficiently to prevent the foliage flagging. The leaves will gradually decay, when the pots may be placed in any dark place having a temperature of about 45°. The plants that are now showing flowers must be watered regularly. They should be grown in a house where the minimum temperature is not below 60°. When they have ceased flowering gradually reduce the water supply and mature the combs as above described.

FERNS IN ROOMS (Constant Reader).—Plants of Maidenhair Ferns will continue fresh for a considerable time in the window of a living-room, especially if the plants are shaded from the sun and are copiously watered. They will be further refreshed by placing them outdoors during an occasional gentle shower. If no rain falls sprinkle them once a week through the rose of a watering pot, so as to keep the fronds free from dust. A window having a north aspect would be a suitable position for the plants. The soil must never be dry.

GRAPES CRACKING (W. Dinsdale).—The cause of your Grapes cracking is an undue quantity of water at the roots after they are colouring or approaching ripeness. Never let your Vine roots suffer by want of water while the berries are swelling, and when they are fully grown keep the border rather dry till the fruit is cut. Let there be no mistake, however, about the watering, but when it is done always let it be thorough. If you cannot give and withhold water at will, then cut down your Muscat Champion and replace it with a Black Hamburg.

CUTTING AND PRESERVING EVERLASTING FLOWERS (F. R. D., Cardiff).—Cut off the flowers when they are not more than half open, tie them up in small bunches, and suspend upon a line in a cool dry shed, and when thoroughly dry keep them in a box or drawer to preserve them from dust, and see that they do not suffer from damp. Xeranthemums are best dried in a dark closet, and afterwards kept from the light till required for use, as they are apt to lose colour. The same precaution may be adopted in drying your Helichrysms and Rhodanthes should you experience any difficulty in fixing the colours.

FUCHSIA FLOWER TUBE SPLIT (Ecce).—Splitting of the tubes usually arises from the atmosphere being too moist or from moisture coming in contact with the flower, and often follows a period of very bright weather, and as a rule is confined to the white-spalled varieties, especially those of robust growth. There is no remedy but more uniformity of temperature and atmospheric moisture.

STORING VEGETABLE MARROWS (F. J. I.).—They should be cut as soon as the rind becomes hard and yellow. Choose a dry day for collecting them, and store them away in any dry but not very warm place.

LIQUID MANURE FOR ROSES (E. B.).—You may use guano at the rate of 1 lb. to twenty gallons of water. Soot also makes a good application at the

rate of a peck to thirty gallons of water; but liquid manures, good as they are, do not compensate for efficient manurings and surface dressings of rich material. These, with thorough waterings in dry weather, produce good Roses and good foliage.

DENNSTEDTIA DAVALLIODES YOUNGII (R.B.).—You do not state the nature of the particulars required. Perhaps the following extract from Veitch's catalogue, page 22, 1877, will afford you the desired information:—"For this splendid Fern we are indebted to the kindness of J.R. Young, Esq., of Sydney, N.S.W., with whose name it is associated. It is a native of the New Hebrides, of very robust habit and vigorous growth. The rhizome is creeping; the fronds are of noble proportions, attaining a length of 10 feet and upwards, and have stout erect or sub-erect stipes, quite smooth, rounded on one side, and flattened on the opposite or upper side with a furrow running along the entire length. The leafy portion of the frond is arching, bi- and tripinnate, broadly lanceolate, and acuminate. The pinnae are sessile or subsessile, spreading. The rachides furrowed on the upper side like the stipe. The pinnules are finely cut and of a light cheerful green. The aspect of the whole frond is very airy and graceful. It is a grand Fern for a warm conservatory. For a central subject in grouping, where bold and spreading foliage is required, it will be found a great acquisition to our decorative resources, and as an exhibition Fern it will be invaluable."

BOILER FOR HEATING (W. W. E.).—We cannot advise you. Consult some practical gardeners in your neighbourhood or some large nurserymen.

OYSTERS (South Hants).—We have no knowledge of the Acts.

NAMES OF FRUIT (R. T.).—Calebasse Grosse. Let us know what soil it grows on, and where, and we will endeavour to suggest a cause for the fungoid attack. (W. Allingham).—Duchess of Oldenburg.

NAMES OF PLANTS (James Shearer).—1, *Empetrum nigrum*; 2, *Achillea Millefolium*; 3, ditto; 4, *Equisetum arvense*; 5, *Caulis Anthriscus*; 6, *Galium aparine*. (G. O. S.).—1, *Saponaria officinalis*; 2, *Lobelia sp.*; 3, *Melilotus leucantha*; 4, *Phygelius capensis*. (Type).—*Abutilon Darwinii tessellatum*. The Begonia is, we think, *B. nitida*, but it is difficult to determine from a single pip. (W. R.).—We cannot identify from leaves only. (Rev. Dr. P. H.).—We think it is *Cordylina indivisa*. (J. Bale).—1, *Pteris monstrosa*; 2, *P. cretica*, var. *albo-lineata*; 3, *P. cretica*; 4, *Asplenium fecundum*; 5, *Adiantum pubescens*; 6, *Aspidium falcatum*; 7, *Adiantum cuneatum*.

THE HOME FARM:

POULTRY, PIGEON, AND BEE CHRONICLE.

THE CULTIVATION OF RYE.

THIS has always been a crop of importance not only in this country but abroad. In many continental states it is almost the only crop grown. In parts of Russia, Hungary, and other countries, and in some of these districts abroad, it enters largely into consumption as food for the poorer sort of people, but it makes coarse dark flour, and is deficient in nutritious properties as compared with that of wheat. It is, however, sometimes in this country made into meal with barley, &c., where the price of the grain makes it profitable in admixture; but since we have had such large importations of Indian corn it is not often that the price will enable it to compete with Indian corn as a feeding material for cattle, pigs, &c. At present rye is chiefly used for sowing to produce an early fodder crop; and upon the large stock farms, where numerous flocks of sheep are maintained, it is of the utmost consequence to provide a good supply of early food in the spring, and particularly in those seasons where there is a partial or serious failure of the root crops. As soon as this failure can be ascertained, which is usually soon after harvest, it is well to look forward and provide for scarcity in the spring by sowing a good breadth of rye to fold off with sheep. It not only provides for them in the spring, but the land after rye is fed off is left in the best state for the growth of roots to follow, our own experience of this matter being that Swedes and common turnips are both more sure to take and certain to plant regularly after the rye crop than after a long winter fallow. When fed by sheep eating cake, &c., the land will not require any further manuring for the root crop, especially if it is a kind soil suitable for the growth of roots. It is advisable at sowing time to ascertain as near as possible the acreage required, and to sow no more than can be consumed within a given time. If it is required for soiling horses and cattle it will only be in season for about fourteen or sixteen days before the trifolium will be ready for feeding; but when the rye is required for hurdling off for sheep it can be commenced ten or twelve days earlier than for cutting up to feed animals at the stalls.

Upon the home farm the growth of rye will often have to be considered in quite another way now straw is so dear. Rye may be sown unusually early in the autumn and receive a liberal dressing of guano, say 2 cwt. per acre at the time of sowing, or a

dressing of 1½ cwt. of nitrate of soda in February or March, so that not only the heaviest but the earliest crop may be obtained. The produce, instead of being used as food for stock, may be reserved for the sake of the straw, and may remain until it comes into ear. This it will do in ordinary seasons on kind land under the before-named treatment about the first week in May. It may then be cut and tied into sheaves and set up on one-third of the land, when the other two-thirds may be cultivated and sown with mangold, carrots, Swedes, &c., the rest of the land being finished off when the sheaved rye has been carted and stored away for use as straw only. It may, however, be carted loose somewhat earlier and partially dried in order to make hay of, like the Americans do with wild oats, and in this way it makes capital fodder if not too much heated in stack.

Rye is usually grown upon poor sandy or gravelly land, and it pays very well to harvest the crop, as there is always a demand for it for sowing; but it should be drilled and hoed if the land is subject to weeds, because it does not meet with a ready sale if the sample contains the seeds of weeds. It may, however, be grown upon the better sorts of land, when it will pay well as a cereal crop, especially if the object is to obtain a crop of stubble turnips after the rye is harvested, for it not only comes ripe a fortnight before the wheat crop, but on good land it will yield a large produce, the value of the grain being generally higher in price than barley for grinding purposes. The preparation of the land is of the greatest consequence, because the succeeding crop being of necessity put in immediately after the rye is cut, it is therefore essential that the land should be perfectly free from couch grass at seed time. It often happens that there are only a few bunches of grass to be seen, which should be forked out before ploughing, as it saves the expense of more ploughing, harrowing, rolling, &c., and also saves time, for it is very important that rye should be sown early; and as it generally follows a wheat crop it may then be put in immediately the land is cleared of wheat. The quantity of seed required is from three to four bushels per acre when the crop is intended for early cattle food; but from two to three bushels is quite enough when the rye is to remain and harvest the grain if the land is in good heart and condition. It is also very desirable that the seed sample should be clean and free from the seeds of weeds, which is not always the case, for generally speaking no cereal crop is taken less pains with by the farmers than rye. Although rye will succeed well on very poor soil if properly tilled and manured for, still it is best sown where the climate is dry and warm, and is therefore not often grown in cold, late, and exposed districts, because oats would answer better and produce a more valuable crop in backward situations and high altitudes. If grown under such circumstances for feeding purposes rye would come too late, as the chief value of the crop depends upon its adaptation for early feeding.

There are two sorts of rye—the common or ordinary sort, which is usually met with in the market, and the Giant or St. John's-day rye as it was called when it was first introduced upwards of thirty years ago. The common sort is a small and thin grain, whereas the Giant rye is a much longer and stronger grain, being stouter in sample and particularly distinguished by a roundness or plumpness on the back of the grain. The Giant rye is also stronger and earlier in growth, with longer and stouter straw, but it is not considered so hardy as the common sort, and therefore not so well suited for poor land and exposed situations. It is, however, worth notice on account of its productive qualities, and will yield a heavier bulk of fodder to cut up for cattle at the earliest period; it should, however, be sown earlier than ordinary rye to obtain the full advantage of the sort. The grain, being larger than common, will necessitate a full allowance of seed; and in order to prevent the lodging and twisting of such a bulky produce it will be desirable, when the crop is intended to be harvested for the grain, that it should be drilled at 12 inches apart in the rows. It will stand up much better, and be more likely to yield a full crop of the most valuable grain and give a full crop of long reedy straw, so valuable at the present time for various purposes either for use

or sale. This sort of rye, when drilled at the wide distance, offers a capital opportunity for being seeded in the months of February or March with broad clover. The best plan of so doing is to sow the clover seed and hand-hoe or horse-hoe between the rye, which will effectually bury the seed and prevent the necessity of harrowing or rolling; and this is important with a crop like rye, which makes such an early leafy plant in the spring. The object of seeding with broad clover is a valuable one, and similar to that which we have often carried out with early white oats. By reaping the corn above the clover as soon as the corn is carted away the clover in ordinary seasons will make quick growth, so much so that in many seasons we have cut up for foddering a heavy produce down to the first week in November without injury to the clover plant in the following summer.

WORK ON THE HOME FARM.

Horse Labour will still be employed in carting the corn and pulse crops to the stack or barn. At intervals, however, other work must be found for them, and this will depend very much upon the style or system of farming adopted. If the ordinary four-course rotation of cropping is pursued it will be wise, seeing that stubble turnips will be seldom sown, to go on with the autumn tillage of corn stubbles upon land coming in for root crops next season. This will be necessary upon the mixed soils, which are often more or less infested with couch grass; but on many of the chalk-hill farms in various counties, and also upon some of the light-land farms not given to couch, the horses will be employed in laying out farmyard dung upon the lea ground intended for wheat. It is, however, sometimes imagined that laying out and spreading dung thus early that it loses some of its properties, but on chemical analysis this is not found to be the case, and it then becomes a question as to whether it would be best to proceed and plough in the dung without further delay. This must, however, in a busy time like harvest, be a question of opportunity, for such-like work in fine weather must not be allowed to interfere with stacking the corn crops.

The odd horse or horses will still be required in horse-hoeing the late turnips and carting of green fodder daily for the horses, cattle, and pigs; and in case proper foresight has been used the green fodder of the home farm will be available for a long time yet. Although the second growth of clover will be rather old and dry, the other crops provided, such as late vetches and oats mixed, spring-sown trifolium, and the third cutting of lucerne, will each in turn be found in good condition for soiling cattle and horses at the stalls.

Hand Labour will still be employed principally in harvest work, for although in the early districts the wheat will have been stacked and the ricks thatched, the barley will still require attention, and be cut and tied into sheaves or carted as loose corn according to the condition and growth of the straw. We have at the present time barley so laid and twisted and so broken by storms that it would be difficult, and probably impossible, to cut with the machine and tie into sheaves. We have, therefore, no alternative but to cut it with the scythe or fagging hook, whichever may be safest, to avoid cutting off the ears of corn, and harvest it as loose corn. Much of the oat crop is found to be in some districts in the same laid and twisted condition, and must be treated accordingly as circumstances may require. At any rate, it seems advisable in such a stormy harvest as we have hitherto experienced to put up ricks in the fields where the corn has grown, in order that a larger extent of land may be cleared of the crop in the shortest time and secured in the best condition. This is particularly the case with barley, for it cannot take much rain after being cut without injury to the grain as malting barley.

Upon the home farm it will also be necessary to attend to the pasture and park lands, and, if it has not already been done, the grass and weeds which are often found in patches after the cattle have been feeding during the summer should now be cut over with the scythe, and the grass and weeds immediately raked up and carried away in order to prevent injury to cattle by their eating the heads of grass seed which may happen to be ergoted. There are various weeds which if not carried away as fast as cut will leave the seeds. We have especially noticed in different dry pastures the yellow-flowered ragwort, which is the worst weed we know of. It sheds its seed in a most extraordinary manner, and more than any other weed will be well described by the old lines, "That one year's seeding makes seven years' weeding." It is also necessary in some meadows, particularly those which require to be drained, that the rushes will now be strong and should be cut down and carried away for littering of cattle and pigs. This will weaken the rushes and give a better chance for the after-grass to grow, and a better opportunity for the cattle to feed upon it.

The shepherd will now be required to give particular attention to the sheep which have been recently purchased, as they often fall lame from foot rot in consequence of driving to and from the sheep fairs, and in treating them it is necessary to attend to them every day and dress the feet as fast as the disease appears, and after applying the usual remedies the animals should be allowed

to stand for several hours by themselves in a pen littered with clean dry straw.

CHICKENS DYING.

IN answer to "TWELVE-YEARS READER," we rear many hundreds of chickens. We do not lose two per cent. For four days they are under the hen. They are then put out on the grass, the hen being under a rip. The birds are fed on groats, ground oats, bread and milk, chopped egg, and boiled greaves. They always do well. Failure is the exception, at intervals of some years. This, of course, assumes they are not provided with or tempted with food sufficiently poisonous to cause death. Young chickens are not to be benefited by nostrums. It is very nonsense to suppose sufficient knowledge in any man to prescribe for a chicken. You have made a connecting link between two centuries. In the last century the administration of a peppercorn was held to be a sovereign remedy. The sacrifice of a cock to Esculapius was a panacea, and in our own time we have heard a "wise woman" say, that for a dislocation the white of a new-laid egg laid on with the wing feather of a hen was a remedy.

Hatch your eggs under hens. When hatched keep them a few days in confinement, then put the hen under her rip on the grass. Feed the young on bread and milk, soaked greaves, boiled egg chopped fine, and bruised corn. They will want neither help nor medicine. Observe common-sense rules. If the previous meal is not eaten give no more. If, in spite of this feeding, the chickens still droop, give them stale bread steeped in strong ale. The last we believe would have saved all your chickens.

DURHAM COUNTY SHOW OF POULTRY, &c.

THE annual Show of the Durham Agricultural Association was held at South Shields on the 21st and 22nd inst. An excellent marquee was provided for the poultry and Pigeons, and this proved a great boon.

Poultry was about a repetition of the Ryhope Show, but in consequence of the birds being under canvas a few of the awards were reversed.

Pigeons were a capital entry, almost all classes being well filled, although the Carriers were to some extent an exception, and Short-faced Tumblers had no entry. Tumblers, Long-faced, were very good. Pouters were a grand class, every bird deserving a prize, and two extra prizes were awarded. The first, second, and third were Blues, and extra second and third Yellow and Red. Dragons were good in both classes, and all the six prizes were carried off by the Mansfield loft. In Nuns many were severely trimmed, and in consequence left out of the list. Owls were a very good class; first and second Silver English, and third White African. Turbits were an uncommonly good class, almost every bird noticed, and the prizes awarded to Blues and Reds. Barbs were poor, and Jacobins a moderate lot, as also the Fantails. In Magpies were three of the best Reds that have been seen in the fancy. The Selling classes were well up in quality, and most of the birds quickly changed hands.

There were three classes of *Rabbits*, the best being the Lop-ears, and one of *Cats*.

JUDGE.—Mr. E. Hutton.

CANARY MANAGEMENT.

It is not of uncommon occurrence that accidents happen to Canaries through the want of a little proper management; for instance, a too hurried mode of catching a bird from a cage or fly,

and also allowing the claws of a bird to grow to such a degree that the bird cannot freely hop from perch to perch or on to the wires of the cage without the danger of its sickle-shaped claws becoming trapped. The consequence is that many a valuable pet songster is brought to a premature death.

Respecting the catching or handling of birds I will quote from a chapter in Mr. Hervieux's old bird treatise. He says, "Canary birds sometimes suffer much for want of a little precaution. Sometimes a Canary bird is put quite out of order by being handled too roughly. You will hear him when he is in your hand make a noise like the snapping of a finger. This cry or noise is followed by some drop of blood coming from his beak, and then you may see the bird as it were stunned and not able to extend his wings. You must put him again immediately into his cage, cover him with some thin transparent cloth, and hang him in some place out of any noise of people that he may not be disturbed, set his meat and drink on the bottom of his cage, taking away the perches, and give him good food; if he survives twenty-four hours there is hope that he will not dye [die] of it, but will only be gaunt and thin. This generally only happens to Canary birds that are wild and unruly, being commonly those that have been reared by both cock and hen. To prevent this accident you must use precaution, drawing near the cage out of which you would take the bird by degrees; you must give him notice at a distance either with your mouth or hand, for if he be taken by surprise, though he does not fall into the danger I have spoken of, it often happens that when you miss taking him at first he flutters about the cage till he breaks his head or wings. When you would take a Canary bird that is in a volery [a fly] you may use a sort of little net made purposely to catch them. Some make a little sort of trap cage, which they set into the volery with some sweet eatables in it, as simnels or biscuits; the Canary birds soon run into it, one after another, and sometimes several of them together. Those that are taken in it you put into a cage and return the trap to the volery till such time as the bird you would catch is in it, and then you return all the others you have no occasion for into the volery."

The hand net and trap cage are good ways of catching birds from a large fly or from a room, but in place of the spring "trap cage," which Mr. Hervieux evidently intended for the purpose, I would suggest the use of a cage with a swing door (one of which kind I have adopted), so situated upon the floor of the fly or room that with a length of thread attached the swing door can be pulled to when many birds have hopped therein. I prefer this method to a spring trap, which might in its action break a bird's leg.

Mr. Hervieux certainly had an eye to the danger of a spring trap, for further on in the same chapter he says, "I find this a very convenient way of taking Canary birds out of a volery, and must own this method does not scare them, and consequently they are out of danger of those accidents above mentioned, which happen when taken or caught by hand; but I am sensible of an accident which may happen, and therefore discourages me from practising this way, and that is that as the trap is falling to shut in the birds others may be hopping upon and about the trap door, which falling in the meantime quick and before the birds that are on the edge can be gone they are in great danger of having their claws broken, and sometimes the birds killed; therefore I leave the curious to make choice of what they shall think most for their convenience and being least hazardous for killing their Canaries when they are to take any out of their voleries." The old work in many respects is not only really practical, but somewhat quaint in its style.

Overgrown claws or beaks may be kept down by carefully operating upon the same with a sharp penknife, but not so to pare away the horny substance until there is a danger of blood coming forth. The termination of the thin vein of blood running along each claw may easily be seen by holding up the claws before a strong light, and it is mostly at the extreme point of the beak that the horn will require to be cut away. Respecting the latter operation not one in twenty birds will require its beak reducing, still I have had several instances where the upper mandible has overlapped the end of the lower one by more than the eighth of an inch, and thus hindering the birds from picking up their seeds. The use of plenty of grit sand will tend to keep down the growth of claws, and a piece of the cuttle fish suspended inside the cage will keep down the beak. When handling a bird do so with some care and confidence with the thumb of your left hand over the neck, and so holding the bird that it has not too much play, for I have known many instances of blood vessels breaking when the birds have been held too loose.—GEO. J. BARNESBY.

VARIETIES.

ALTHOUGH a month has elapsed since harvest commenced only a comparatively few fields are cleared of the crops. For miles the grain is still exposed, the great bulk being in stook, but much has perforce remained on the ground untied on account of the heavy rains. In some districts the corn is sprouting, and unless bright days recur and continue for a week or ten days much injury will result. Already the quality of the barley has

suffered considerably, the grain being stained, and not in the bright condition coveted by the maltsters. The crops in well-farmed districts are generally heavy, and more straw is produced than has been the case for some years.

— IT is estimated that 5,000,000 sheep, valued at £2,500,000, were destroyed, directly or indirectly, through the lack of pasturage consequent on the drought that has lately prevailed in Australia.

— WE never saw the root crops on the various farms in Lincolnshire and Yorkshire look more promising than at the present time. The heavy and frequent recurring rains that followed the drought of July have caused turnips and mangold wurtzels to grow with great rapidity, and the crops are in most instances not only full but quite cover the ground. Should the winter prove mild the crops in all probability will be too large for the requirements of the stock, especially as the pastures also contain an unusual quantity of green food. Late potatoes are also looking well, but are in extreme danger of being overtaken by the disease, which is certain to be virulent if the rains continue much longer; already some fields are affected more or less seriously.

— THE "Veterinarian" says that not less than ten thousand head of cattle have been attacked by the cattle plague in the province of Smyrna. It also exists in other localities in Turkey, both European and Asiatic, as well as in Russia in the government of Bessarabia, Volhynia and Podolia. In Italy, the disease prevails in the province of Naples, but the whole of the Austro-Hungarian Empire is free with the exception of the Cattaro district.

— A TRANSATLANTIC contemporary says a farm sixty miles long and ten wide in one tract, mostly fenced, is that of Miller and Lux, cattle monopolists of California. They have 80,000 head of stock, own 700,000 acres of choice land, and are rated as worth \$15,000,000.

— ACCORDING to the recently published agricultural returns for Ireland the number of holdings in the Sister Kingdom is 600,000. The total acreage under crops is 5,203,000 odd, showing a decrease of 62,196; the decrease in cereals was 31,174; in green crops, 87,249. The number of acres under grass is 10,124,745; fallow, 16,971; woods and plantations, 330,816. There is an increase in live stock—that is, in horses and mules, 9953; sheep, 106,721; goats, 13,324; and a decrease in cattle of 12,847, and in pigs of 199,372. The number of scutching mills in Ulster is 1162; Leinster 13, Munster 20, and Connaught 17.

BAR-AND-FRAME HIVES.

UNDER the above heading your correspondent "HARDY OF THE HILLS" gives an interesting account of his visit to his Dunoon friend, and I quite agree with him that pure honeycomb from the super is the best if not the only form it should be put on the table. He must, however, bear in mind that the bees store the various honeys methodically and distinct. His recommendation to sling the contents of the black broodcombs (best given to the bees for their own support) to fill supers is a very questionable procedure. Besides the double labour, waste and loss of time to the bee, such mixed blend could never compare with pure virgin honeycomb collected and stored naturally.

That the first-cross Italian is more irascible than the black or yet pure Italian is a fact familiar, and cannot be gainsayed by any with the requisite experience, which, did your correspondent possess, would readily agree with me that such first-cross Italians store more rapidly and defend it better than the pure bees of either variety.

It is rather fallacious to estimate the value of a district from a single visit, and the comparative merits of bees and systems of management are obviously best obtained by their being wrought side by side in the same district.

Every intelligent bee-master ought to have his bees thoroughly in command by the contents of his hives being moveable. It does not necessarily follow he should be continually pottering and smoking amongst them. During the honey flow the less disturbed they are the better, save giving empty and removing completed supers.

Cottagers of our district working on the swarming system complain bitterly this season of the loss of time watching their bees, and after all the trouble and expense of feeding find that their swarms fly off to people the dead skeps and enrich their careless neighbours who let theirs perish from want. A labouring man when once taught can well appreciate improved management. I remember some years ago one at a job here telling me of an immense skep he had meant to "smeek." To save them from the brimstone pit, for a consideration he consented to let me have the bees provided I would show him how they could be driven. The skep turned out to be the largest straw I ever saw. Comb after comb was cut out, and the loaded tops he carried in to his wife for to run, and on my asking him what he meant to do with the long stretches of brood and empty combs, he said the children would have them to play with and then would be thrown on the

dunghill for the fowls to peck at. He evidently thought me very foolish when I offered him a like sum for the combs as the bees, but rather changed his mind when he saw on fetching them the ease with which they were cut up and fitted into the frames of a Stewarton set of boxes, and his bees introduced, a new and better colony arising phoenix-like from the ruins of his old. It so interested and delighted him that I could not resist presenting him with an improved hive. This he peopled the following season, and he afterwards told me the couple of supers it yielded realised him between £3 and £4, with the stock left over to boot, and that he was for ever done with the old skep plan.—A RENFREWSHIRE BEE-KEEPER.

APIARIAN JOTTINGS.

RETURNING home after a six-weeks absence in Jersey and Brittany I was eager to see what my bees had done, and full of hopes from all I heard and saw elsewhere that a really good honey season might be chronicled at last. Nor on the whole have I been disappointed, for although doubtless had my apiary been planted elsewhere, or had I been at home (which I never am during the greater part of July and August), a greater success might have befallen me, still I have no reason to complain. Of honey certainly there is more than enough for home consumption, and for the surplus I must seek a market.

At page 20 of the current volume of the Journal will be found a statement of the condition of my apiary when I left home. Every possible super had been given to every hive, and everything to tempt the bees up into them; still I found that "the very general complaint this year that bees would swarm" continued to be verified in my apiary, in that "the one strong hive" then recovering from the effects of the tedious spring, which had as yet not swarmed, had sent out a fine colony on the 3rd of July, two days after I left home. The loss of the swarm aggravated the misfortune, as there was no one at home at the time to follow it or hive it. I left the bees in first-rate condition, working in two large supers, filling both with their numbers and every cell below as cram full of brood as it could be. It was also one of my largest hives not bar-framed. In spite, however, of this loss I found one of the supers beautifully filled with honeycomb, sealed throughout, and weighing over 30 lbs. net. The bees had also begun operations in the other super, and laid up a sufficient store in the hive below for winter. I have no means of knowing certainly whether they sent out a second swarm, but it is at least probable they did so.

One of the other "weaker hives" alluded to at page 20 had filled up its hive with comb and sealed up a large portion of it. I took off it also a nice super containing about 17 lbs. of pure honeycomb, and some sealed dronecomb below with over 5 lbs. of honey in it. The other had contented itself with filling up the hive and working a little in a super. They ought to have done more, as the hive was overstocked with bees; but I suppose, owing to the too small passages communicating with the super, they preferred to hang about outside the hive in masses rather than work diligently in it. This hive contained one of my last autumn's best imported Italian queens, so that I have had no advantage from it as yet. It does not appear to have swarmed, and yet it is one of the few hives in my apiary which has retained its drones August 17th.

Since writing the above, it having occurred to me that its drones might be utilised for the production of a race of pure Italian queens, I resolved to remove the queen and give her to another hive, while compelling the bees to rear some queens from her brood; but after driving and failing to find any eggs or brood in open cells it became evident that the old queen must have led off a swarm at no very distant period, for there were still some hundreds of cells occupied by brood sealed in, and several royal cells appeared to have been tenanted quite recently. The queens also refused to be caught, taking wing immediately and flying home straight as a young queen would, entering a temporary hive put there to catch and occupy the attention of homeward stragglers. It is matter of regret that my imported queen was thus lost, having evidently gone off with a swarm; but this young queen ought to be very pure, as there have been very few impure drones in my apiary for a long time. It was also a good opportunity for breaking up a very old hive and transferring the bees to a bar-framed hive, which accordingly we did, intending to feed them up this autumn with sugar.

The same day (17th) I also examined the large bar-framed hive, which had given me two swarms, as recorded, on the 13th and 17th of June. I had cut away a quantity of royal cells having two or three, and a young queen was seen by me at the time perambulating the combs. For all that I found no queen in the hive, only some few hundreds of old bees, and absolutely no honey at all. This hive accordingly was immediately broken up, and after its bar frames had been re-arranged and comb-deviations corrected it was given to the bees, dealt with as described in the foregoing paragraph.

I may mention that in dealing with my bees this autumn my plan is to rob them of every possible pound of honey; accordingly this morning the bar-framed hive into which we hived the prime

swarm, described at page 20 as issuing on the 15th of June (pure imported Italian), was taken in hand. It had given me a perfect little super with about 9 lbs. of honeycomb. Every comb was now taken out except four combs in the centre, which contained brood. These combs alone will remain, but as they run pretty true I purpose putting an empty bar-frame with guide comb between each, and encouraging the bees by liberal feeding during the next six weeks to fill up the intervening spaces with fresh worker combs. They will doubtless breed largely this autumn, as there is a very large population, many of them vigorous young bees.

The extracted comb, after removal of honey by slicing the comb, will be adjusted in another bar-framed hive, and the population of another old hive driven into it to be treated in a similar manner.—B. & W.

OUR LETTER BOX.

INSURING LIVE STOCK (B).—We do not know of any society that insures stock against disease or death.

STRAW HIVES (Wm. Burch).—Mr. James Lee of Bagshot sold straw hives at one time, and for aught we know may do so now; but Mr. Samuel Yates, seed merchant, Manchester, has always a good stock of straw hives on hand, and sells hundreds of them annually. We obtain ours from him. We advise you to accept the condemned bees, which are one-third of a mile from your garden, put them in empty hives, and place them beside your hives for a week or two, and then unite them. If you were to unite them at once the strange bees would likely fly back to the old place. Keep them alive by feeding till they forget their old home.

HIVES (W. H. Hudson).—Write to Messrs. Neighbour, High Holborn, for the information you need.

A HIVE WITHOUT BEES (A. G.).—Your bees, which clustered outside so much in summer and filled a super 12 lbs. weight, while at the present time your hive has not more than half a pint of bees, probably swarmed in July once or twice without your knowledge. The queen which was hatched in it after the first swarm left might be lost on her marriage tour—a common occurrence, and the queenless bees would gradually dwindle down to their present weakly state. Your hive being without queen and without brood, and with very few bees and little honey, makes us think it has come to its present condition in the way indicated above. The price of the best Scotch straw hives in the Manchester market (Mr. Yates') ranges between 4s. and 6s. each, according to size; and English-made ones 2s. each. We use the Scotch-made hives.

REMARKS.

- 21st.—Fine day, but not very bright, and rather cool; very slight shower in evening.
22nd.—A rather dull day; a little sun in the morning, overcast in the afternoon, wet in the evening, and heavy rain at night.
23rd.—Overcast in morning, rain at 11.30, thunder at noon, 0.31 of rain fell between 0.15 and 0.35 P.M., when the sun began to shine, but the thunder continued almost incessant till 1.30 P.M.; heavy showers with blue sky at intervals and distant thunder all the afternoon.
24th.—Dull morning, thunderstorm between 11 A.M. and noon; heavy showers at intervals all day.
25th.—Fine pleasant morning; heavy clouds at 1.30 P.M., making it rather dark, heavy rain from 2.5 to 2.40 P.M., showery during afternoon; fine evening.
26th.—A dull, close, gloomy day; a little sunshine in the morning; fine
27th.—Fine in early morning, but it clouded over and became dull with a good deal of heavy rain; early in the afternoon it cleared up, and the rest of the day was fine and bright.

The weather during the week was unsettled and showery, the amount of rain being considerable. Temperature rather below last week, sun temperature very much below. Barometer low.—G. J. SEMONS.

COVENT GARDEN MARKET.—AUGUST 28.

OUR market has been heavy, and clearances have been hardly effected, all classes of goods being low. Kent Cobs and Filberts are selling freely.

From observations taken near London during forty-three years, the average day temperature of the week is 69.2°; and its night temperature 46.8°.

ROSES IN AUTUMN.

SURELY at no time of the year can the queen of flowers be more appreciated than at the present. It is true that the lordly Dahlia holds high festival in our gardens, that she appears to challenge attention by her splendid bust and form, and to ask, "Can any fault be found with me? My teeth are even, my complexion is slightly dull, is even in colour, and I am always free from spots. Look at me all round and say, Am I not lovely?" We own freely her beauty of form, but we think she is a little stiff—too much like a milliner's block in a shop window, and then indeed her colours are dull. The dews may come and go, the autumn rain may descend upon her choicest blooms, and the sun may come out and try and light up her colour, but in vain. No dewy shades of colour, no softness, no sheen as of a satin, is there. And as to fragrance, well, the less said about this the better. In fact we shall be far more complimentary to the Dahlia if we say she has no scent, than to speak of her fragrance.

Then there is the splendid *Gladiolus*. No words can aptly and fully describe the varied beauties of this glorious flower, but it again has the same essential lacking to make it perfect—fragrance. Asters, with their somewhat ragged blooms, and Stocks make our parterres gay, but still do not compensate us for the lack of fragrance in the flowers of autumn.

Then there is the lovely *Lilium*, the queen of autumn flowers; here we have indeed all we want in form, and colour, and fragrance, but the very sweetness of these beauties is almost too much for us. It is a cloying perfume partaking too much of the nature of the *Narcissus*; and once more we turn to the Rose to give us all we want. And here again as much if not more, as in summer, the glorious Rose repays us tenfold for all the love and labour we lavish upon her. She may not bloom so freely, it is true, but that makes her flowers all the more precious in our eyes.

The giant "Hercules" can no longer walk through his lines and cut twenty or thirty fine blooms of *Marquise de Castellane* at a time as he does in June, but he can wander about and find here and there a bloom which will bring back to his mind the past glories of his summer victory, and stir up grateful feelings in his heart.

The blooms may not be so large, it is true, but they are quite large enough for what we want now. A few blooms for the autumn shows and the rest for the decoration of our houses, this is all we want, and this in August and September we can have. As to fragrance, I assert without fear that the bouquet of Roses in autumn, when the heavy dews descend at night and morning, and the frequent rain refreshes the hot earth, is much more sweet and delicious than in summer.

I have been in the lucky and privileged position of late to visit some of the largest nurseries where the Rose is cultivated, and have made it my special object to take notes on autumn Roses. The result of these notes I hope to

convey to the readers of the Journal; and if there is any difference of opinion as to the judgment I have formed I can only say that I have taken notes from four gardens of the greatest rosarians in the country, and there is an old saying which surely may be considered true in this instance, that seeing is believing.

The first nursery that I visited was that of Messrs. Thomas Rivers & Son of Sawbridgeworth. This old firm, once the very foremost in the Rose tournament, and almost the *fons et origo* of the Rose Show, now no longer exhibit; they are content to rest upon their well-won laurels and leave the course to other and younger firms. A most extensive nursery, or rather nurseries, is that at Sawbridgeworth, and one that would afford material for many articles in the Journal were I competent to write on fruit and other choice gifts of Nature; for there are but few flowers which Mr. Rivers does not cultivate largely.

It was on a very stormy morning in the last week in August that I paid a visit to Sawbridgeworth, but I could not defer my visit till the weather improved, as my stay in London was very limited. I cannot hope to do justice to any department of that great nursery, but can only give a few impressions which the place made upon my mind.

I went very carefully through the Roses with a view to discovering the best autumn bloomers, but I did not find so many blooms as I expected. The late stormy weather no doubt accounts for this, but the plants seemed to be ripening very fast. The leaves were disappearing, and the plants appeared to be almost ready for removal even at this early date.

The freest bloomers were undoubtedly the Tea Roses. This is a most valuable section for autumn blooms; far more flowers can be cut from Teas than from four or five times the number of Hybrid Perpetuals. Adam is a very free bloomer in the autumn, and Céline Forestier also. *Souvenir d'un Ami* and *Marie Van Houtte* also are good bloomers at this season. *Triomphe de Rennes* and *Madame Falcot* both come to the front in August and September. I do not remember to have seen any blooms of *Souvenir d'Elise*; but *Madame Willermoz* and *Souvenir d'un Ami* were both well represented. After the Teas and *Noisettes* I place the *Bourbons*. Nearly all the old favourites of our fathers are to be found giving good blooms at this season. *Souvenir de la Malmaison*, *Catherine Guillot*, *Sir Joseph Paxton*, *Queen*, *Baron Gonella*, *Aimée Vibert* were all covered with blooms and doing as well or better than they do in the summer.

Of Hybrid Perpetuals the best I could find was my old favourite *Boule de Nègre*. *Capitaine Christy* ran her very close, however; and *La France*, *Mrs. Rivers*, and the *Baroness* were good stable companions. Of coloured Roses perhaps *Jules Margottin* and *Paul Neyron* were the freest bloomers; but that excellent variety *Sultan of Zanzibar* proved to me that she possessed another virtue hitherto unknown to me—viz., that of a good stayer or autumn bloomer. *Prince Camille de Rohan*, *Duke of Edinburgh*, *Duchesse de Cambacères*, and *Alfred Colomb* were all doing well; while that little gem *Elise Boëlle* held up her tiny head as perky as if she was as big as *Paul Neyron*. *Annie*

Wood, Marquise de Castellane, and Souvenir de Dr. Jamin showed many good blooms.

Now I must try and say a few words about the fruit trees. I was perfectly astounded with what I saw. House after house full of Peaches and Nectarines and Apricots, and above your head Grapes of all kinds. It was a case of Peaches to the right of you, Peaches to the left of you, and Peaches above you. Wherever you looked you saw this delicious fruit. Peaches trained to wires and growing like Grapes; Peaches in toy pots bearing twenty or thirty apiece; standard Peaches planted out and weeping over your heads. I always heard that Mr. Rivers was the father of Roses in this country; but, bearing in mind what he had done for fruit, I think he might adopt a new motto to his coat of arms—"Fons et origo *Mali*."

I saw one house 375 feet long filled with upwards of twenty varieties of Grapes, the grandest and most prolific of which was Madresfield Court. I was shown a corner of the nursery where there were nearly seven hundred seedling Plums, every one different. I saw Apples, Pears, and Plums trained as cordons in the simplest and yet most cunning manner. One device was a most ingenious one. It was a double cordon: the Pears were trained obliquely on one side, and on the other side in the opposite direction, thus taking a double advantage of the sun and winds at the same time.

Every now and then we came to a patch where the Pears had not done equally well. Mr. Rivers accounts for this in what to me is a most novel idea. He thinks that there are waves of frost as there are waves of the sea: that there are currents of cold air which go over the ground in waves, so that one place is frozen, another left cold. If it is not so, how do you account for Pears of the same variety, in the same soil, and treated in exactly the same manner, showing such different results? With regard to the old Rose Gloire de Dijon I omitted to say that Mr. Rivers told me he was the first to see this grand old Rose at Dijon before it was sent out. It was at the nursery of M. Jacotot that he found it.

I was most kindly received and most hospitably entertained by Mr. Rivers; and I can best conclude these somewhat rambling notes and most inadequate description of his really splendid place by saying how much I enjoyed my visit and how grateful I am to him for the kindness which he showed to a—WYLD SAVAGE.

THE POTATO CROP IN ESSEX.

DURING the present season I have grown about twenty varieties of Potatoes, and in recording my experience with them generally shall be well repaid if my remarks may help to induce others to give theirs. The Potato is undoubtedly the most popular vegetable grown, consequently any information, however slight, cannot fail to be interesting to the majority of the readers of this journal. In taking charge of this garden I was informed that the Potatoes usually grown in it were unfit for use, being, in fact, when cooked little better than "lumps of soap;" the greater part of the supply had therefore to be bought. I certainly found the soil in the garden the reverse of a good Potato soil. It was naturally a stiff clayey loam on a cold gravelly clay subsoil: it had not been double-dug for thirty years, and had been literally poisoned with manure, no corrective in the shape of hot lime having been administered. Where such treatment is given (and this is not a solitary instance) it is no wonder that "soapy" Potatoes are obtained. The remedy successfully applied was the often-described process of double-digging (not trenching; that will not do here), which, however, to be explicit I will briefly describe. The top spit and shovellings of the width of the trench are taken out and wheeled to the end of the length, the bottom spit is then broken up, a liberal quantity of manure added, and the next top spit and shovellings are turned completely on to this, &c. No manure was added to the top spit, the only thing needful being to well fork it over to incorporate the "shovellings," which are in fact almost virgin soil, with the rich soil underneath. Shallow planting was resorted to, placing the rows a good distance apart, according to the habit of varieties, and moulding-up pretty heavily. Last year but few complaints were made, this year none, instead of which the quality of the tubers has been highly commended.

My object in growing so many varieties is for the twofold purpose of being able to select the most suitable varieties for growing here and on similar soils, and also for exhibition purposes.

The best variety for forcing I found to be Veitch's Improved

Ashleaf, and in cold frames for succession Mona's Pride. Porter's Excelsior and the American variety Alpha are both well adapted for forcing, but the quality is inferior to the foregoing kidneys. On the early borders Mona's Pride proved the best, being the hardiest, most productive, and of good habit and quality. Veitch's Ashleaf is slightly superior to it in quality, but on the whole is scarcely its equal. The Early Hammersmith is another excellent variety, and will become very popular. The habit is good, and the tubers very shapeable and of good quality. Rivers's Ashleaf does not do well here, although near here on a lighter soil it is remarkably prolific and good.

For a second early Snowflake is a great favourite, and is undoubtedly one of the handsomest and best varieties grown. A variety known as Badsaye's Kidney will be largely grown another season, being good in every respect. In all probability it is grown under another name. I had my stock from Shropshire. Waterloo Kidney produced a good crop of clean shapeable tubers, but the quality is inferior. Early Rose crops heavily, and the tubers are of good shape; the quality, however, renders it unfit for the table. This and other American varieties should be grown in moderate quantities only, as should a wet season ensue they are comparatively useless; on the other hand, should it prove a dry season they are almost invaluable, cropping heavily, and the tubers of the best shape and quality. These remarks are particularly applicable to the American variety Breadfruit. It was equal to the Snowflake for appearance and quality, and more prolific last season, and is quite as good this season. Sutton's King of the Potatoes is a good variety, the haulm is short, and the tubers are produced freely, of good quality and shape. A peculiarity of this variety is that it produces both kidneys and rounds on the same growth. Lady Paget and Lapstone are very similar, and are yet dissimilar. The former variety proved the best last season under the same treatment, and the latter this season. Both are heavy croppers, and for either quality or shape are unsurpassed. Prince Arthur is a good variety, and ought to be in every collection however limited. It is one of the heaviest croppers tried here, and the tubers are very clean, shapeable, and of the best quality. Magnum Bonum is, as far as quality is concerned, the best late kidney, but unfortunately it is of much too robust a habit, the crop being scarcely proportionate. It crops well in poor and rather dry positions (under Apple trees, &c.), which is a good recommendation. The foregoing are all kidney-shaped, given in order of succession. The following are rounds, similarly arranged:—

Fox's Seedling proved the best early, and is undoubtedly a good old variety, quite worthy of resuscitation. Alpha, an American variety, is decidedly the earliest round tried here, but, like Porter's Excelsior, is scarcely at home on our soil; neither variety, however, will be quite discarded. Rector of Woodstock is rather small, but is in every other respect an excellent variety. It makes but little haulm, at the same time the rows ought at least to be 2 feet apart and well moulded up, the roots being very much inclined to ramble. Model is a really good variety, and is rightly named. A good companion is a variety known as the Scilly Red or Carter's Main Crop; both are very productive, handsome, and the quality good. Schoolmaster is a decided acquisition to the late varieties; it is good in every respect, and, what is a great desideratum, matures early, very late-growing varieties being comparatively worthless in this immediate neighbourhood. A good selected strain of the Victoria Regent does well, and the quality is unsurpassed. This season, unfortunately, it is very much diseased, The Red-skin Flourball is grown principally for baking, but it is rather too coarse for boiling. Large quantities of it are grown in the fields, and is by the growers considered an excellent variety—not exactly disease-proof, but less liable to it than many varieties. Most of the Potatoes now in the ground are badly diseased, but we took the precaution of lifting early and before the bad weather set in. The Victoria Regent matured late, and half the tubers have the disease; the others are almost free of it. Lapstone, Model, Prince Arthur, Breadfruit, and Magnum Bonum commenced growing afresh, or supertuberating. This is the case with most of the late crops in the fields, and will apparently be allowed to go on—a practice far from being commendable, as the growers will be benefited at the expense of the consumer. The crop will undoubtedly be heavier, but the quality will be sacrificed.

As before stated late-maturing varieties are comparatively worthless here, simply because usually experiencing dry summers, the crop from light soils being very poor, and on the

other hand if planted on heavy soils it is usually spoilt by disease, this season being unfortunately no exception to the rule. If limited to eight varieties I should select *Mona's Pride*, *Bad-saye's Kidney*, *Snowflake*, *Model*, *Carter's Main Crop*, *Prince Arthur*, *Schoolmaster*, and *Magnum Bonum*.—W. IGGULDEN, *Orsett Hall*.

THE AURICULA APHIS.

I AM in despair, and am almost tempted to say I must give up my favourite flower, for I find this abominable pest as rampant amongst my plants as ever. When I repotted them I took every precaution. All the plants were well cleaned, the loam I used came from Hampshire, and the leaf mould from a distance, and I am sure there was nothing in the soil. The plants thrived well, the pots soon became full of roots, and I thought I was rid of the plague; but on my return from Scotland in July I was told it was on one of my plants at the crown. I then turned out some others, and in one form or another it was, I am sure, in nine out of ten plants; but, strange to say, they exhibited no outward trace of suffering. The foliage was healthy, and where it was otherwise they were evidently out of sorts from some other cause. In my trouble I wrote to my friend Mr. Llewelyn, who told me that he had found some of it at the time of repotting, but that by using a solution of soft soap and tobacco powder, and plunging the pot, plant and all, into it, he had got rid of it. This was good news to me. I adopted his formula, dipped my plants, but to my disgust I find the aphid alive and prospering under the treatment.

The question now arises, From whence has come this fresh invasion? Is it the result of some nidus left on the plants, or does the same cause exist to produce the infestation as that which caused it at first? I am afraid the latter is the true state of the case, for I have found the same aphid (at least so far as I can judge) on the roots of the Lettuce and even the Sowthistle. Hence I am afraid the place is full of it, and do what I can I shall not be able to keep the plants free from it; for if it can fasten itself on the roots of a plant which has only a few weeks of life, how much more likely is it to effect a lodgment on a perennial like the Auricula?

But then comes another question, What is its effect on the plant? I have said as yet I see no marked change in mine. I have examined the roots, and find that where the aphid is clustered on one of the long fleshy roots that still it seems to grow on, and I do not find any of that set appearance which Mr. Horner speaks of and which I found on some of my plants last year. Some weeks ago when I first rediscovered it, and before I knew that so many of my plants were affected, I placed a plant of General Neil on which I found it apart, and have watched it from day to day. The plant grows and looks vigorous and healthy. I have therefore determined not to repot my plants, to try some other remedy, and if it fails to let them remain until the spring. As soft soap has failed I shall try Gishurst. By the way, the plants did not seem to dislike the soft soap at all.

I have mentioned the name of my friend Mr. Llewelyn, and I am sure all who know him will deeply feel for him in the great domestic sorrow he is suffering by the loss of one of his sons, accidentally drowned while bathing on Caswell sands near Swansea on Tuesday last.—D., *Deal*.

THE WARS OF THE ROSES.

I MUST decline to accept the position assigned to me by "WYLD SAVAGE" among exhibitors of Roses when he says, "It is almost a certainty that these two (Messrs. Baker and Jowitt) are first and second at any show; then comes Canon Hole." At the last Exhibition of the National Rose Society, held at Manchester, I took the first prize offered to amateurs (£10 for forty-eight varieties), Mr. Jowitt the second; Mr. Baker telegraphing that his bloom was over.

I cannot, as a rule, exhibit my Roses in their integrity before the 6th or 8th of July; but when they are at their best, and not injured by vernal frosts, to which I am much exposed, I fear neither "Gog" nor "Magog" (not happy titles for amiable rosarians!), and hope to be where I found myself not many weeks ago—at Manchester and Spalding. The Rev. E. N. Pochin, placed fourth on the list, has shown Roses unsurpassed for symmetry and size, and may possibly repeat the performance when he has removed from the disadvantages of a change of residence; and I know some other rosarians who, not possessing

at present the extensive collections of my friends at Exeter and Hereford, would produce Roses of equal, if not superior, merit in smaller quantities. I may mention, for instance, the Roses exhibited by Mr. Soames of Irnham Park at the Crystal Palace, Maidstone, and Manchester.—S. REYNOLDS HOLE.

LOOK TO THE FRUIT TREES.

THE reason why the failure of the fruit crop has been so general has been asked repeatedly. Two reasons have been given—cold and wet in the autumn of last year, cold and wet in the spring of this year; the first preventing the ripening of the wood, the second the development of the fruit. Everywhere blossom was abundant, but in most cases when the fruit came to be looked for it was not to be found, and we were invited to consider and show cause for its so-called mysterious disappearance. Well, I suppose nobody is prepared to gainsay the reason why as I have explained it, and if that is granted let us then inquire if we have no remedy for such a lamentable state of things. I for one think we have no perfect remedy, but am convinced that much may be done to ameliorate the present state of things. A few weeks ago, when driving through the Weald of Sussex near the foot of the South Downs, I saw several Apple trees heavily laden with fruit in many of the snug cottage enclosures and orchards which I passed, affording proof that the trees derived important benefit from the sheltering belts of trees and hedgerows by which they were enclosed. Driving with Dr. Hogg about a year ago through another part of the same district, we went past a small garden open to the road, but completely shut in by trees on the north and east, in which the fruit trees were literally bending beneath their load of fruit. "There," said our Doctor, "see the value of shelter." I might adduce other examples, but the fact of the value of shelter is so well established that my object is rather to urge the application of such knowledge in actual practice than to convey information about that part of my subject.

For the present moment let me advise care and caution in pruning, for I much fear that the immature condition of the wood in spring is often traceable to late summer pruning. To prune a tree hard now is to induce buds that would otherwise remain dormant till spring to start into growth, and, however fine the weather may be throughout autumn, such growth cannot possibly become mature. If, then, the growth is so much crowded as to darken the interior of the trees prune the shoots, but leave them 5 or 6 inches long, so that when growth ceases you may shorten them to full plump buds near the base and upon firm well-ripened wood. When an undue amount of shade is not thrown upon the centre of the tree, then I prefer giving the shoots a twist about 3 or 4 inches from the base and turning the tips downwards, thus imparting a check in the flow of sap to such a nicety that the bottom buds swell almost to bursting, but do not burst until next spring, the mutilated "twist" being pruned away in winter.—EDWARD LUCKHURST.

BATTERSEA PARK.

MUCH as Battersea Park has been admired during past years, and numerous as have been the visitors, it has never been more attractive than during the present summer, nor so largely patronised. The park has been brighter in brighter years, but this year the intense greenness of the lawns and the exuberant growth of trees, shrubs, and ornamental-foliaged plants have abundantly compensated for the absence of glowing masses of Geraniums which could not be produced, or at any rate could not long continue, during such dripping weather as has recently been experienced. Flowers earlier in the season were numerous enough—spring flowers and early summer flowers, flowering shrubs, herbaceous flowers, and bedding plants; but the season for many of these has passed, and foliage tall and stately as in the subtropical plants, and bright and lowly as in the carpet beds, is now in the ascendant.

Yet there are flowers now. The bushes of *Althæa frutex* in the shrubberies richly laden with fine Hollyhock-like blooms are very beautiful. Masses of Dahlias, glowing "Pokers" (*Tritoma Uvaria*), charming groups of that fine autumn herbaceous plant *Anemone japonica alba*, Lilliums, rows of *Chrysanthemum frutescens*, *Salvia patens*, and *Pentstemons*, also *Calceolarias*, *Ageratums*, and a remnant of Geraniums and *Lobelias* are represented, so that there is no lack of cheerfulness. But the foliage plants constitute the chief charm, and

some of these also have attractive flowers—notably the Cannas, which are unusually luxuriant and fine.

Four distinct kinds of garden embellishment are well represented in this park—namely, mixed borders, which are almost always attractive; flower-bed massing with Geraniums and kindred flowers—very gay for a time, but transient, this year very transient; subtropical gardening, which is highly imposing; and carpet bedding, which to the great majority of visitors is perhaps the most attractive of all modes of decoration.

The mixed borders contained the first flowers of the year, and will yield the last. They are not herbaceous borders strictly, but include all sorts of flowers that will flourish in them, and are thus not merely interesting, but are gay, bright, and sweet. To take away these mixed borders would be to deprive the park of one of its chief charms, and certainly the most fragrant: there is, however, no fear of such a calamity, for each year the borders appear to be better than before, and it is evident they receive the attention that they so well merit, and for which they give such a satisfying return. No masses of flowers in the park surpass, if equal, the fine groups of *Anemone japonica alba* now flowering in the mixed borders.

The bedding-out section (flowers) has this year been the least satisfactory of all. The plants were as fine as plants could be, and about 65,000 Geraniums alone were bedded-out, and proportionate numbers of *Calceolarias*, *Ageratums*, and *Lobelias*. These were gay, very gay, for about a month, but the late rains have despoiled them of their beauty. A few of the best bedding Geraniums are John Gibbons, rich crimson scarlet, fine; Edward Sutton, scarlet, very good; Mrs. Lancaster, perhaps the best pink; Lady Sheffield, pink, fine; Capt. Harrison, scarlet; Mrs. Russell Gurney, scarlet, white eye; and Miss Wakefield, cerise scarlet, fine truss. The best silver-edging Geranium is Princess Alexandra, and the best dwarf golden bicolor is Earl Rosslyn. The best *Lobelias* are Ebor, very dark, dwarf, and rich; and Kaiser Wilhelm, stronger grower, fine for large beds.

In striking contrast to the flower beds referred to are the stately and commanding groups of subtropical plants. Some of the beds of these are now splendid, and equally so are the isolated specimens on the lawns of *Musas*, *Palms*, *Aloes*, &c., while the Fern dell and vista are quite charming. Perhaps the finest bed in the park is a large oblong planted with *Canna Van Houttei*, edged with *Amaranthus melancholicus ruber* mixed with *Abutilon niveum variegatum*, and margined with *Dactylis glomerata variegata*. The bed is raised above the level of the lawn, and the *Dactylis* droops down the slope like a fountain of silver. The mixture of the *Abutilon* and *Amaranthus*, too, is strikingly effective, and associates well with the rich mass of *Cannas* which occupy the centre of the bed. *C. Van Houttei* has purplish bronze foliage and produces its bright crimson-scarlet flowers freely. It is one of the most effective of the dark-foliaged varieties for large beds. A few other of the more useful of the *Cannas* may be appropriately noticed here. The old green-leaved variety, *C. Annei*, is one of the most luxuriant in growth of all, and is represented by grand masses 8 feet high; it has small pale yellow flowers. Much finer as regards flowers, indeed the best of the yellow-flowering varieties, is *C. Annei grandiflora*, the flowers of which are very large and bright. The best green-leaved variety of moderate growth is perhaps *C. peruviana*, and the richest dark-leaved sort is *Adrian Robinii*; this has remarkably rich foliage, and will probably be more extensively grown in future. *C. Prince Imperial* is perhaps the best of the dwarf-growing varieties. The sorts named all possess merit, and are well adapted to the various positions in which *Cannas* are grown. Another grand bed in this section is planted with *Polhymnia grandis*; the plants are unusually luxuriant, and show plainly that this is one of the finest subtropical plants in cultivation. *Wigandia caracasana* has an undergrowth of variegated *Veronicas*, crimson *Lantanas*, and *Plumbago capensis*—both stately and pretty. Of a totally different character is a bed of *Buonapartees*, fine specimen plants, one of them flowering; each plant having a green carpet of *Sedum lydium*, the general groundwork of the bed being of Golden Chickweed. Another bed of the same nature is planted with tall *Cordylines*, having a groundwork of *Iresine Lindenii* intermixed with *Gnaphalium lanatum*, and a belt of *Chamæpuce diacantha* in a carpet of *Sedum glaucum*, the bed having a margin of *Alternantheras* and *Echeveria glauca metallica*. Totally different, again, and one of the most pleasing beds in the park—

one which combines elegance with brilliancy in a remarkable degree, is a raised bed of Tuberous *Begonias* dotted thinly with *Jacaranda mimosæfolia*. The *Begonias* are laden with flowers, and their bright colours shine attractively through the graceful foliage of the *Jacaranda*. These *Begonias* evidently require a somewhat raised position, yet sheltered, to display them to advantage. Another *Begonia* flowering freely in association with fine-foliaged plants is *B. ricinifolia*; it has leaves, as its name suggests, almost exactly resembling those of the Castor-oil Plant, and flowers not unlike those of *B. manicata* but larger. Another bed near contains *Eurya latifolia* and *Fuchsia Sunray* as a groundwork, but not closely pegged, and a canopy of *Acacia lophantha*: it is very chaste. *Fuchsia Golden Treasure* is the best of the yellow-foliaged varieties, and affords a cheerful belt to such plants as *Ricinus*. *Cannabis gigantea*, *Ferdinandias*, *Solanums*, *Grevilleas*, and *Ficus* are represented, and the distinct *Polygonum Sieboldii* has a stately yet graceful appearance: a newer variety, *P. sachalinense*, has larger foliage, but is not more generally attractive than the old favourite. A bed containing healthy and well-coloured plants of *Pandanus Veitchii* attracts notice, as also does a fine group of *Brugmansias* with pendant trumpet-shaped flowers; and another group, totally dissimilar, of the Coral Plant *Erythrina Crista-galli*.

"Fern Hollow" is every year one of the most admired portions of the park. The most striking plant this year is a splendid specimen of *Pritchardia pacifica*, than which a finer example is seldom seen at exhibitions. Another conspicuous plant under the Tree Ferns is a massive specimen of *Pothos acaulis*, which in the distance resembles a huge Bird's-nest Fern. In the background are large *Philodendrons*, *Bananas*, *Cycads*, &c.; trained to the trunks of the trees is *Monstera deliciosa*, and in the foreground stumps covered with *Platyceriums* produce an unique effect. The long vista opposite has a similarly cool and refreshing appearance, the smooth undulated lawn and banks being overshadowed with the fronds of *Palms* and *Ferns*, resembling a tropical forest scene in miniature.

Many isolated specimen plants dotted on the lawns must be passed, but one demands notice—a grand example of the Abyssinian *Banana*, *Musa ensete*. This is the terminal plant of one of the picturesque nooks with which the park abounds. This nook, near the Fern and Palm groups alluded to, is flanked by fine masses of *Cannas* edged with *Funkias*; but the terminal plant is the chief object. The principal leaves including footstalk measured a few weeks ago 11 feet 6 inches in length; they are enhanced in beauty by their deep red mid-ribs. It is feared that this imposing plant has grown too large for its winter quarters, which cannot but be regretted. It is such plants as these that distinguish the London parks from the majority of private gardens, and it would be well if the Government could feel justified in providing structures suitable for preserving such valuable specimens. The admirable manner in which all the parks are managed, the suggestions they afford, and the lessons they teach in decorative art, also the real enjoyment they contribute to thousands of visitors from all parts of the country, are reasons why all the aids possible should be afforded not only to sustain but to increase the fame and prestige of these important public gardens.

The carpet beds yet remain to be noticed. The notice must be brief, because it is next to impossible to render the appearance of the beds intelligible without giving diagrams of every bed. It is noticeable that blue *Lobelias* are quite dispensed with in carpet-bedding designs. They are too uncertain in growth to be relied on, and they are only in beauty during a limited period; for this reason no flowering plants are employed in carpet beds, nor none are needed. Beds of plain outline are the most suitable for this mode of embellishment, such as circles and oblongs, beds of fantastic shape not permitting designs being well displayed in them. In this style of bedding a great effect can be made with a few varieties of plants. Thus the largest carpet beds in this park are occupied with Golden Feather and *Alternanthera amœna* arranged somewhat after the pattern of a Turkey carpet, and the combination of these two colours is highly effective. The beds have an edging of *Antennaria tomentosa* margined with *Sedum acre elegans*. A round bed has central mass of *Alternanthera amœna*, narrow scrolls of Golden Feather enclosing masses of *Alternanthera amœna*, the angles and edge being occupied with *Leucophyton Brownii* margined with *Sedum acre elegans*. Another circular bed has a central diamond of *Alternanthera paronychioides* major; four designs of *Alternanthera amœna* enclosed with

Golden Feather, and angles of *Veronica repens*, a green carpet plant of much promise and employed for the purpose for the first time. Those beds are very beautiful, the *Alternanthera amœna* being especially rich. But the favourite beds, judging by the manner in which the public crowd around them, are what are popularly termed the "coffin beds," a somewhat gloomy yet withal an expressive term. There are two beds each nearly 20 feet long and 6 feet 3 inches wide near the broad end, tapering to 4 feet 6 inches at the narrow end. The two beds are divided by a circular bed 6 feet 6 inches in diameter. A diagram of this circle is submitted to show the extreme simplicity of the planting; also of one of the long beds (fig. 27), the other being an exact counterpart.

Fig. 27.

- 1, Raised edging, *Echeveria glauca* (double row).
- 2, *Alternanthera amœna* (double row).
- 3, 3, 3, Golden Feather (narrow line).
- 4, *Mentha Pulegium gibraltaria* (groundwork).
- 5, *Sedum glaucum* edged with *Kleinia repens*.
- 6, *Alternanthera paronychioides major*.

The whole of the centres are planted with *Alternanthera* surrounded with narrow lines of Golden Feather. These impart colour, lines of the same plants being arranged near the margin of the bed forming an admirable balance; but perhaps the chief charm consists in the 6-inch band (5 in the diagram), of *Sedum glaucum*, with an edging next the Golden Feather of *Kleinia repens*, the erect growth of which appearing above the *Sedum* is highly effective yet extremely chaste. The colours are well displayed by the green groundwork of *Mentha*, and the whole arrangement evinces taste in conception and skill in manipulation, for in point of finish the beds are as

near faultless as we can imagine beds to be. The round bed (fig. 28), has a margin (1) of *Sedum acre elegans*, a band (2) of *Leucophyton Brownii*, and an inner line (3) carried round the rays of the star and circle of *Alternanthera amœna*, the rays and centre (4) being planted with *Sedum glaucum* dotted with *Pachyphyton bracteosum*, and the angles (5) with the same *Sedum* dotted with *Cacalia tomentosa*. The appearance of this bed is quiet and sober, and shows to advantage the two long beds which it divides, and with which it is associated.

Fig. 28.

Other portions of the park deserve notice, but only one can be alluded to—the Alpine Garden, and this only because it places under the eye at a glance five green carpet plants—namely, *Pyrethrum Tchihatchewi*, excellent for large banks and dells; *Leptinella scariosa*, with its much-toothed leaves, and well adapted for the same purpose; *Cerastium arvense*, too dull in colour and unlevel in growth to be recommended; the *Mentha* above referred to, admittedly one of the best green carpet plants; and *Veronica repens*, dwarf, rich, green, the only real rival the *Mentha* has, and likely to be heard of again. To make a sixth green carpet plant there is in an adjacent bed *Herniaria glabra* of low slender growth and graceful, yet somewhat dull in colour. The two most useful plants of this nature are the *Mentha* and *Veronica*.

It is pleasing to hear that, while it is not unusual for 25,000 visitors to assemble in the park during Sunday evenings in summer, it is very rare that any injury is done to plants, shrubs, or flowers—the best proof that the excellent work of Mr. Roger, the Superintendent, and his assistants is appreciated.—J. WRIGHT.

GRAPES SHANKING.

Is the shanking of Grapes more than usually prevalent this year? It is so with me, not because the Vine roots are too dry, for abundant supplies of water have been given to the inside borders, and to outside also during hot dry weather; nor is it because of stagnant moisture at the roots, for the borders rest on the limestone rock and water gets away quickly; nor is it on account of overcropping last year or this, for the Vines which bore the lightest crops both seasons are the worst shanked.

The Vines (planted in a span-roofed house 40 feet by 20 in the spring of 1874) are very strong, the foliage large, leathery, and clean. They are Black Hamburg, fine in bunch, berry, and colour, and scarcely a shanked berry; Alicante, good bunches, no shanking; Madresfield Court, good bunches, large berries, a few bunches shanked at the tips; Dr. Hogg, fine long bunches, some few shanked at the tips; Buckland Sweetwater, large loose bunches, very large berries, many shanked in every bunch; Muscat Hamburg grafted on Black Hamburg, splendid bunches, but more than half the berries gone—this has always behaved badly; Ferdinand de Lesseps, no shanking; Golden Queen, a strong three-year-old Vine with only three bunches, which look as if they would go altogether; a Black Hamburg and Madresfield Court planted in a narrow border in the middle of house, which cannot get a drop of water except from the can, have each a good crop with not a berry shanked, and quite up to the mark in size and finish, though densely shaded by the roof Vines.—BLACK HAMBURGH.

THE TRANSFUSION OF ESSENCES.

HAVING recently read your remarks on the transfusion of essences in the Journal of the 15th ult. leads me to believe that other cases of it may interest you, though perhaps the one I have to record is a more common occurrence.

In January last I inserted buds of last year's growth of the White Sweetwater Vine into the main stem of a Black Hamburg. Three of them grew; two are bearing fruit, and are

now ripe, one bunch on each. The one is true to character in every particular, so also is the other except in colour, which is as black as the Hamburgs. They have been seen and tasted by our friend Mr. Robson of Linton and others; but the bunches, though somewhat reduced in size, still remain on the Vine to be seen by any who may like to look at them. I hardly like to cut them, or I would send you a few berries of each in proof.—W. B., *Preston Hall, Aylesford, Kent.*

SANDY HORTICULTURAL SHOW.

AUGUST 30TH.

A PLEASANT and appropriate site for a show, with good approaches and convenient railway accommodation at the junction of the Great Northern and London and North-Western lines in the midst of a fertile market gardening district studded with gentlemen's seats, a liberal subscription list, a well-organised Committee, and, above all, energetic Secretaries, form a combination of advantages which have enabled the Sandy and District Horticultural Society to hold in a small village one of the best of local shows. The Society is indeed fortunate in being thus privileged, and had it not been for the frowns of Jupiter Pluvius in the early part of Friday last I might have recorded the Exhibition as a perfect success.

The Show was held in the stately little park of Sandy Place, kindly lent for the occasion (as is his custom) by J. N. Foster, Esq. The site was within five minutes' walk of the two railway stations, and notwithstanding unfavourable weather the Show was attended by many thousands of visitors, and it is hoped may prove a financial success. The whole affair is usually carried out on such a scale and with such spirit that only those who have not been to the Sandy Show previously need be surprised. The Society embraces under its fostering wings not only plants, flowers, fruits, vegetables, and dinner-table decorations, but Mangolds and other roots, cereals, Beans, big Gourds, live and trussed poultry, honey, butter, cage birds, live bees, needlework, and darning!—a tolerably wide field with scope for most tastes, and to judge from the earnestness of the attendant visitors each department had its zealous admirers. The excellent band of the Coldstream Guards under the leadership of Mr. F. Godfrey, and a public dinner under the presidency of J. Shuttleworth, Esq., the Society's President for the year, served as agreeable counter-attractions.

The Show altogether occupied nearly a dozen large marquees, and the magnificent plants exhibited by Mr. J. House of Peterborough and Mr. Parker of Rugby, who divided honours in the open class, and by Mr. John Cook, gardener to Col. Stuart of Tempsford Hall, and Mr. Rabbitt, gardener to Major-Gen. Pearson of The Hassells, Sandy, who were each successful exhibitors in that department, were a great attraction; but, as might be expected in a market gardening county, fruit and vegetables were the strong points of the Show. The former occupied nearly the whole of the centre table of a marquee nearly 100 feet long. For the open collection of six varieties of fruit in baskets there were nine competitors, the first prize falling to Mr. Tillbrook, gardener to B. Brown, Esq., of Houghton, who had good Black Hamburg and Muscat of Alexandria Grapes, Peaches, Melon, and Golden Drop Plums, all thoroughly ripened; Mr. R. Waller, gardener to J. Howard, Esq., Bedford, coming in a good second. Several good collections were also shown in the amateurs' and cottagers' classes. As the highest prize offered for any collection of fruit was only 15s., it appears that large prizes are not always necessary in order to procure a good show; indeed it is a healthy sign, and it is fair to presume that, in this district at least, exhibitors are not always worshippers of Mammon, and that advancement of the craft has more weight with many than the desire for gain. For black Grapes the first prize was awarded to Mr. J. W. Shepherd, gardener to F. Martin, Esq., Great Staughton, Hunts, for two extremely fine bunches of Black Hamburg, but which were slightly wanting in colour; and the second to Mr. G. Claydon, gardener to J. H. Astell, Esq., Woodbury Hall, for two smaller but well-finished bunches. In white Grapes Mr. Redman, gardener to — Goodgames, Esq., Eynesbury, was first with good Muscat of Alexandria. Mr. G. Clutton, gardener to Mrs. Percival, The Bury, Arlesey, was first for Scarlet-fleshed Melon with Duke of Edinburgh, and Mr. W. Rachelous, St. Neot's, for a Green-fleshed with Eastnor Castle. Peaches, Nectarines and Plums were also shown remarkably fine, the latter especially so; the first prize for kitchen Plums going to Mr. George Vigne, gardener to J. H. Thornton, Esq., Kempston Grange, for twelve Kirke's, and for twelve dessert Plums to Mr. Parker, Waresley Park, for Reine Claude de Bayay. In the cottagers' class, too, Goliath was shown large and well ripened.

Vegetables were shown in open, market garden, amateurs', and cottagers' classes, and an immense display was the result. For the collection of eight varieties, open to all, the basket shown by Mr. R. Waller, gardener to J. Howard, Esq., was almost faultless, and a better basket of cleaner stuff all just fit for table has rarely been seen at more important shows; Mr. Robinson, gardener to F. Howard, Esq., Abbey Close, Bedford, being a good

second. Creditable collections were also staged in the amateurs', market gardeners', and cottagers' classes. Of course, in Bedfordshire Onions were an important feature and almost a study—they might indeed be said to vie with the "noble tuber" for supremacy; but the latter being represented in strong force did not seem inclined to bow to the claims of its more fiery compeer, for notwithstanding the recent rains and state of the atmosphere an immense variety of clean, smooth, and well-ripened Potatoes free from disease were shown.

The first prize in the open class for twelve round Potatoes was awarded to Mr. Waller for a very good type of the Schoolmaster, and the second also for Schoolmaster. All through the Exhibition this Potato was shown remarkably well, and it fully justifies the award of a first-class certificate made to it by the Committee of the International in 1876. Nearly all the specimens consisted of clean though rough-skinned, almost perfect balls of good size. It is not only a Potato to look at but a Potato to eat, and, if I am not mistaken, it will do credit both to Mr. Bennett, the fortunate raiser, and to Mr. C. Turner who sent it out. For twelve kidneys Mr. J. Hills, the Sewage Works, Bedford, was first with fine specimens of Fenn's International; Mr. Rodwell, Biggleswade, being second with Myatt's. For the collection of Potatoes, six sorts, three round and three kidney, six of each, there was a very strong competition, several good collections having to be placed under the tables. Mr. R. Waller was first with a well-matched lot, very clean and sound, and not too large, consisting of Schoolmaster, Late Rose, Model, Bresee's Prolific, Snowflake, and Brownell's Beauty. In the market gardeners' class for a collection of Potatoes, twelve of each variety, Mr. George Kirby, Arlesey, was first, showing very good specimens of Early King, Extra Early Vermont, American Breadfruit, Model, Myatt's Prolific, Rector of Woodstock, a good unnamed red kidney, apparently Red Fluke; Early Rose, and Giant King, not unlike Early King, but with a few more eyes; Red Peerless (fine) and Challenger, a variety in appearance much like Schoolmaster. Mr. John Cox of the Three Counties Asylum, Arlesey, was second with larger specimens, but not quite so clean. The following varieties were also noticeable as useful exhibition sorts—viz., Radstock Beauty, round, splashed red, something like Marchioness of Lorne; Peach-blow, very good; Snowflake, shown both as round and kidney; Alpha, very smooth and white; Blanchard, Vermont Beauty, and Sutton's Early, which appeared to be Magnum Bonum.

Onions were good, especially the White Spanish, of which two different types were shown, the majority of exhibitors having the ordinary variety with a pale greenish skin, whilst in two collections a variety not quite so perfect in form, but equally large, with a pinkish yellow-tinted skin, was exhibited. Good specimens of the Blood-red and White Globe were also staged, the latter varying in shape from an urn to a perfect globe.

Cucumbers were largely exhibited, some of the field-grown ridge varieties reaching 16 inches in length, but nearly all showed a tendency to swell at the point, being evidently free seeders. For the best brace of frame varieties Mr. Rabbitt and Mr. Tillbrook were placed equal first, the former with a matchless but well-matched brace of Tender-and-True, the latter with a very fine black-spined variety unnamed; and Mr. Waller was close up as second, again with Tender-and-True. Peas for the season were also good, the best shown being Ne Plus Ultra, Omega, British Queen, Criterion, and Fillbasket. Intermediate Carrots, called in the Schedule "St. James," were well shown. Turnips also, especially a White Globe variety staged by Mr. R. Facey, cottager of Goldington, were remarkably white, sound, of perfect form and yet good size; but upon the whole roots showed a tendency to fork, a complaint which is general and attributable to the season.

The heaviest Gourd showed by Mr. Joseph Holmwood, gardener to J. N. Foster, Esq., weighed 154 lbs. There were also some immense but perfect specimens of the Large Red and Drumhead Cabbage which attracted considerable attention. Tomatoes were also good and well coloured, those shown by Mr. R. Facey in his collection of vegetables would not disgrace the best growers.

The show of cut flowers was good, and included Roses; Mr. John House of Peterborough being first with some fine autumn blooms, including Auguste Neumann, a Rose which always stands well; Duchesse de Vallombrosa, clean but small; Star of Waltham, fine; Hippolyte Jamain, and Baron Hausmann. In the twelve varieties, amateurs, Mr. D. Sewell, St. Neot's, was first, having neat blooms of Niphetos, Pierre Notting, Duke of Edinburgh, Hippolyte Jamain, and Mlle. Victor Verdier; Mr. John Burton of Sawtry was second with a very creditable stand well set up, including Pierre Notting, John Keynes, Devienne Lamy, and Mlle. V. Verdier. The Rev. E. Fellowes, Wimpole Rectory, Royston, was third, having fresh blooms of Souvenir d'un Ami, Marechal Niel, and Etienne Dupuy. A good stand not for competition, mounted on black velvet and with ample foliage, from Mrs. Sewell, showed to much advantage. Gladioli were not largely shown; a good six, however, came from Mr. P. Meyer, Orwell. For Dahlias (twelve Show varieties) the Rev. E. Fellowes was first, and for six Fancies Mr. P. Meyer,

Asters were remarkably good, especially the incurved or Chrysanthemum-flowered, for which Mr. Fellowes was first, Mr. Tillbrook second, and Mr. Redman third; for twelve Peony-flowered Mr. Tillbrook was first with a very fine stand, Mr. Redman second, and Mr. Meyer third; for German Globe varieties Mr. Fellowes was first with some distinct and well marked varieties. Double Zinnias were the finest I have seen, and all the usual colours seem now to be represented in large and perfectly double flowers, an immense advance having been made in this attractive flower during the past decade. Mr. Meyer was first, and Mr. Tillbrook second. African Marigolds were shown very large and fine by Mr. Meyer, and Mr. Tillbrook was first for French. Verbenas were unattractive, being principally staged as single blooms. Coleus, Caladiums, Fuchsias, and Zonal Geraniums included some well-grown plants, and a very brilliant specimen of Coleus Duchess of Edinburgh attracted much attention.

In a very good competition for dinner-table decorations Miss Pearson of The Hassells, Sandy, was deservedly first, the delicate flat blue of *Plumbago capensis* being considerably used with good effect; Miss A. Raye of Tetworth Hall was second; and Miss H. Astell, Woodbury Hall, third. All the exhibits in this class were meritorious and showed good taste. For bouquets Mr. H. Rempton, Ely, was first; Mr. R. Parker, Waresley Park, second; and Mrs. Sewell third. For button-holes Mrs. E. T. Leeds Smith, the wife of the energetic Honorary Secretary, was first with a very prettily mounted trio.

An exhibition of live bees, notwithstanding the once-feared pains and penalties, drew crowds of interested spectators at 3d. each; and if in the twentieth century suffocation is still in vogue amongst bee-masters it will not be the fault of the Rev. H. R. Peel, Hon. Sec. of the British Bee-keepers' Association, to whom humanity owes so much. The exhibition of bees was conducted by Mr. Baldwin of the Alexandra Palace, the expert to the Association, kindly assisted by Mr. Huckle of King's Langley. It was here where one of the first exhibitions of the kind was held. Honey as shown in the comb was free from brood, but several supers were rather dark in colour from having been kept too long in the hive, whilst that shown in glass jars in a liquid state by Mr. S. Hone of Ashwell was of a brilliant light golden colour, and very clear. The first-prize Kohl Rabi from Mr. T. J. Cranfield of Roxton were large and perfect in shape. The best Barley was shown by the Rev. J. Richardson of Sandy Rectory, and the best Wheat by Mr. John Cox of the Three Counties Asylum, and Mr. G. Matthews of Beeston.

The show of poultry and cage birds was also a success.

The management at Sandy is unusually good. Open showing is in vogue, and the names of the exhibitors are printed in red ink on the class cards; but in consequence of the absence of the description of the class which is usually written or printed on the cards, and the insignificant size of the number as written on the cards, some confusion followed, the exhibitors rarely placing the proper card on their exhibits. A good plan of having blue cards for first prize and red for second is followed; and where there is so much good it appears like cavilling to point out a defect, but the exhibiting of large stove and greenhouse plants on lofty staging is a terrible eyesore, and must add much to the labour of the exhibitors as well as to the risks and expense. The Society would do well also in future to discourage, especially amongst cottagers, the showing of unripe fruit and vegetables, and to encourage the correct naming of the specimens—a palpable defect at this Exhibition, and one which takes away much of the educational advantage to be derived from a horticultural show.

The Society and the public are much indebted to Mr. Foster for the use of his pretty and admirably adapted grounds, and to the Rev. J. Richardson for throwing open the attractive rectory gardens; the tasteful bedding-out, however, in both places showing unmistakeable signs of the early autumn season and the late rains. At the rectory visitors were much struck with the beauty of a magnificent old plant of *Plumbago capensis*, which covers the whole back wall of a large conservatory and is a glorious sight.

The Society seems altogether admirably appointed and supported, and the Exhibition is a credit to the neighbourhood.—T. LAXTON, Bedford.

DRESSING CARNATIONS.

I DO not grow Carnations either for exhibition or for the decoration of the garden, for the simple reason that unless I wire every bed I should not be able to preserve a single plant from the rabbits; but I am very fond of the plant, and I know several of the largest growers both amateur and professional, and I have exhibited Roses at a sort of joint show where Carnations were shown. I had never seen florists dressing their flowers before, and I must express my opinion that it was a very unedifying sight. The lovely flower was seized by the scruff of its tender throat, much like a poor victim is seized by the dentist, and a pair of ivory tweezers were employed in pulling every single petal out of its place. "I say, old fellow,

have you seen these Carnation fellows dressing their flowers?" said a brother rosarian to me. "They are like a lot of ladies' maids," I answered, "preparing their mistresses' heads for a ball."

It was most amusing work watching them; and certainly the difference they made to their pets, and the improvement or the reverse that they effected in Nature's handiwork, was so great that I am sure the dame herself would not have recognised her children. Now is this right and proper? If it is, how is it that this, so far as I am aware, is the only flower which is manipulated in this way? How is it that we rosarians are content to show our blooms as they are grown? What would be thought of a man who fastened down with gum or some cosmetic the inmost petals of the somewhat thin Etienne Levet, or of the operator who applied some sort of contrivance which held the Rose in a grip like a vice and prevented its opening? No end of a row would be made about it, and quite properly too.

If this practice goes on we shall come to this: It will not be the best florists or the best flowers that will win; it will be the most skilful operators and the most highly dressed and artificial flowers that will carry off the prizes. Such a result may be wished for by some florists, but it is altogether repugnant to the feelings of a—WYLD SAVAGE.

NOTES FROM KEW GARDENS.

STATICE ROSEA is a charming novelty in the Temperate house at Kew. It is a shrubby species with erect branches, and is in contrast to all others for pot culture in the merit of pink or rosy flowers. The one deficiency is that of dwarf habit, which might be improved by crossing. It is native of Natal. *Habrothamnus fasciculatus* in the same house is now the most showy of greenhouse shrubs. Every branch is terminated by a panicle of red flowers, and these after some time will be succeeded by beautiful berries of similar colour. Fuchsias here are a good feature; they are planted in the beds and trained to tall stakes, by which they form conspicuous floral columns, and admirably relieve the green shrubs around.

In the Palm house are several attractive plants. *Dichorisandra thyrsoiflora* is attractive on account of its deep purple flowers, which open in long succession, and in company with massive foliage makes an effective specimen. *Pancratium speciosum* is one of the best stove bulbs; it flowers freely, and is easily cultivated. The pure white flowers with long and narrow segments are perfect in their way. Another fine plant in flower is *Lagerstromia indica*; it makes a graceful much-branched shrub with small leaves, and now profusely bearing pretty pink flowers, peculiar in appearance from the long and slender claws of the petals. It is equally worth the trouble and attention to which the majority of stove flowering shrubs are indebted for their decorative value. *Crinum Moorei*, flowering in the cool end of the T range, is one of the best species; it has large well-formed flowers of the most delicate pink colour. Though nearly, if not quite, hardy, it is best grown under glass, attaining out of doors some slight degree of coarseness. For greenhouse decoration it is of great value, flowering well and keeping in good condition with the slightest attention. In this division are many varieties of the tuberous-rooted section of *Begonia*, affording good opportunity for selection. The largest flowers appear often in company with the worst habit, and probably much remains to be done in combining the several good points. This group appears to be more than ever popular, and the number of seedlings raised must be immense. An interesting hybrid, raised by Colonel Trevor Clark between the so-called genera *Ismene* and *Elisena*, is flowering here. It has much the appearance of *Ismene calathina*, one of its parents, and not partaking conspicuously of *Elisena*.

Flowering in the Succulent house is the rarely seen *Adenium obesum*, a gouty-stemmed Apocynad bearing handsome crimson flowers. *A. speciosum* has also been freely in bloom. This is nearly allied to the last, and it also grows in the desert, *A. obesum* coming from Aden, after which town the generic name is taken.

TROPÆOLUM SPECIOSUM.

WHEN, three years ago, I first saw this beautiful plant in Scotland and was so struck with its appearance, I was told that it would not do in the south, or if it did that it could only be grown on a north aspect; and this opinion concerning it is

so prevalent that one very eminent firm to whom I wrote, asking why it was excluded from their lists, replied that it was so disappointing that it would not grow except in a north aspect, and even then would not flower, and so they had omitted it from their catalogue. It is high time that these fallacies should be discarded. Two years ago Mr. Duthie, the gardener at Penninghame Castle near Newton Stewart, where I saw it in great perfection, kindly sent me some roots. I planted them in a bed under my dining-room window, the aspect being as nearly south as possible. Last year the plants grew and had a few blooms; they were left undisturbed, and this year they have grown and flowered most luxuriantly, in fact as freely as I saw them in Scotland at the same age. The truth is that all that it requires is to be let alone. As soon as it gets established it commences to flower vigorously, and each year more and more so. In passing through the Trossachs this year I saw the front of the manse, which stands high up and fully exposed to the sun, covered with it; and unless in very hot and dry situations I believe it will do quite as well with us southerners as in bonnie Scotland.—D., *Deal*.

[The small spray enclosed is admirably flowered and very beautiful.—EDS.]

ROSES IN POOR SOIL.

I HAVE read the sorrows of "WYLD SAVAGE," and should not have tendered advice unless he had requested it. I do not like tendering advice, for it seems to argue superiority, which I do not feel.

My advice to him is to trench a portion of his ground, and take out all the stones; then manure the ground and plant the Roses deeper than usual, and place the stones in a radius round the plants. Stones are an excellent mulching; as the ground under them is always kept moist by the evaporation being arrested. Roses suffer from evaporation. Properly the whole ground should be mulched.

Manetti Roses when planted should be covered 2 inches over the roots with soil; a trench should be dug, and soil and manure should be trodden as hard as possible against the stocks, the scion eyes in the stock having been cut out.

Instead of renewing the soil, sow now the Early Stone Turnip, and eventually chop them up and dig them in. The vegetable matter will do great good. I tried it some years ago and found it succeed. If "WYLD SAVAGE" can obtain cow manure, liquid and solid, he will find it advantageous to his Roses. I use it here chiefly liquid, and I never in twenty-seven years have known my Roses do so well as this year. They promise me a fine autumnal bloom. I can strongly recommend Star of Waltham and Queen of Waltham; they are two of the best Roses that I have bought for some years. They are of fine outline, are full to the centre, and abundant and free bloomers. In conclusion, I think Maréchal Niel and Louis Van Houtte to be the two finest Roses; to which may be added Charles Lefebvre, Alfred Colomb, Marie Rady, Madame Lacharme. The two first do better on the Giffraie stock than on Manetti.—W. F. RADCLIFFE.

CHOICE GARDEN ORCHIDS.—No. 4.

VANDA, *Lindl.*

ETYM.—*Vanda*, the Hindoo name.

This genus contains some of the most beautiful of the Old-World Orchids; they are all natives of tropical Asia. Until recently but few species were known; the rigid search for new plants during the last few years, however, has considerably increased our knowledge and added several beautiful kinds to our collections. Vandas are characterised by their coriaceous leaves, which are arranged in a two-ranked (distichous) manner, which, however, vary much in length in the different species. The flowers are for the most part large and highly coloured, the outer portion of the flower—that is, the sepals and petals, being usually alike both in shape and size, the labellum more or less saccate and three-lobed, the middle lobe being large and fleshy.

CULTURE.—The details given in our previous notes upon the genus *Aërides* will apply with equal force for the genus now under consideration. Special care must be taken that these plants do not suffer by want of water during the season of rest, or the lower leaves will at once turn yellow and fall off, to the great disfigurement of the specimen. They enjoy a high temperature, with the atmosphere well charged with moisture, saving the one or two exceptions which we have

noticed specially in describing the species. For further details see *Aërides*. Temperature—Summer, 75° to 85° day, 65° to 75° night; winter, 65° to 70° day, 60° to 65° night.

Vanda Bensonii, Bate. (Bot. Mag., t. 5611).—This is a very beautiful species, belonging to the same section or having some affinity with such kinds as *V. Roxburghii*, &c. Leaves channelled, obliquely toothed at the apex, coriaceous in texture, 6 to 8 inches long, and dark green. Raceme erect, longer than the leaves, twelve to fifteen-flowered. Flowers some 2 inches in diameter, lax, and borne upon long footstalks.

Fig. 29.—*Vanda undulata*.

Sepals larger than the petals; both are obovate, obtuse, furnished with a claw at the apex. Colour yellowish green, with numerous reddish brown dots, reverse side china white. Lip ovate in front, with a bifid apex traversed with three ridges, and having two small triangular side lobes, which are white, the centre lobe being deep violet. Spur conical, obtuse, white. It blooms usually in early summer. Rangoon. 1866.

V. cristata, Lindl. (Bot. Reg., 1842, t. 48).—A curious and beautiful small-growing species. Leaves channelled, recurved, truncate at the apex, and bright green. Raceme erect, shorter than the leaves, three to four-flowered. Sepals oblong, obtuse. Petals narrower and incurved, white tinged with green. Lip oblong, convex, traversed with furrowed lines, and curiously horned at the apex. Colour buff, striped with deep purple,

and spotted with brown. Spur short and conical. Early spring and summer. Nepal, Bootan, and Sikkim. 1840.

V. Denisoniana, Rchb. fil. (Bot. Mag., t. 5811).—This is a small-growing handsome species. Leaves ligulate, somewhat recurved, thick and fleshy in texture, unequally bilobed at the apex, about 8 inches in length, and dark shining green. Raceme ascending, five to six-flowered. Sepals and petals reflexed, cuneate oblong; the latter hastate, pure milk white, tinged with greenish yellow at the apex. Lip same colour, stained with orange round the mouth of the spur, bearing a bilobed callus at its base and five elevated ridges on its disc. Spur short, obtuse, downy on the inside. May and June. Burmah.

V. alpina, Lindl. (Bot. Reg., 1838.) Syn., *Luisia alpina*, Lindl.—A small-growing species, which when not in flower bears a great resemblance to *V. cristata*. Leaves channelled, recurved, two-lobed at the acute apex, frequently with a stiff point between the lobes, dark green. Raceme erect, two to four-flowered. Sepals and petals oblong, the former the largest, of a uniform pale apple green. Lip yellowish green, streaked with blackish purple, oblong, the hollow base intensely black, apex swollen and slightly notched. May and June. Khasia, at 5000 to 6000 feet elevation.

V. insignis, Bl. (Bot. Mag., t. 5759).—This is an extremely rare and very little known species, a variety of *V. tricolor* generally passing for it, from which, however, it is abundantly distinct. "Leaves channelled, linear, but slightly narrowed at both ends, closely imbricating below, obliquely truncate at the ends, 10 inches long and upwards of 1 inch broad, deep green. Raceme pendulous, shorter than the leaves, three to eight-flowered. Flowers spreading, 2½ inches in diameter. Sepals obovate spatulate, obtuse, and fleshy. Colour bright ochraceous brown, with darker brown blotches, reverse side white. Petals similar, but not so broad. Lip three-lobed; side lobes small; middle lobe fiddle-shaped, spreading out in front into a semilunar concave link of a rosy red. Disc furnished with two low ridges. Spur compressed, obtuse, and recurved." It blooms during May and June. Moluccas. 1868.

V. Roeburghii, R. Br. (Wight's Icon, No. 916).—A dwarf-growing plant, which on account of its not being so showy as some of the more recent introductions, has been to a great extent neglected. It is, however, a very handsome and desirable species. Leaves lorate, channelled and keeled below, oblique and three-toothed at the apex, deep green. Raceme erect, about same length as the leaves, bearing from three to eight flowers. Sepals and petals oblong obovate, obtuse at the ends, with slightly undulate margins. Ground colour white beautifully chequered with purple. Lip three-lobed; middle lobe convex, bluntly ovate, notched at the front, rosy red; lateral lobes acute, and about same length as the column. July and August. Assam. 1810.

V. Cathcarti, Lindl. (Bot. Mag., t. 5845). Syn., *Esmeralda Cathcarti*.—A rare and beautiful species somewhat remarkable from its lax habit of growth. It would seem to enjoy an exceedingly moist atmosphere. Want of attention in this matter has led to the inference that the cultivation of this species is beset with unusual difficulties. Leaves 6 to 8 inches in length, linear oblong; the apex oblique and two-lobed; the lobes rounded, not acute; surface of the leaves uneven and pale green. Raceme ascending, longer than the leaves, two to four-flowered. Flowers measuring 3 to 4 inches in diameter, thick and fleshy in texture. Sepals and petals about equal, roundish oblong, concave and sessile. Ground colour pale yellow, profusely streaked with horizontal lines of cinnamon brown, the reverse being white. Lip three-lobed, furnished with a short claw; lateral lobes very small, white streaked with reddish brown at the base, auriculate; middle lobe reniform with an incurved margin. Colour yellow within, outside white. Disc at the base furnished with two erect truncate calli. It blooms during spring and early summer. Native of hot, wet, shady valleys in Sikkim, at 2000 to 3000 feet elevation. 1866.

V. undulata, Lindl. (fig. 29). Syn., *Vanda Goveze*, Hort.—This very distinct and very little known species we believe we have the pleasure to figure now, for the first time in this country. It is a very slender-growing plant, and should be a valuable addition to the cool house, as it grows naturally at considerable elevations in the forests with *Pinus Khaysiana*, where snow frequently falls. Stem about the size of a goose quill. Leaves distichous, linear-oblong, obtusely bilobed at the apex, thick and fleshy in texture, dark green above, paler below. Raceme ascending, 6 to 12 inches long, and branching. Flowers numerous. Sepals and petals about equal, linear-lanceolate,

much waved on the margins, and pure white. Lip linear-acute, also white, stained on the disc with yellow. The flower much resembles a miniature *Cœlogyne cristata*. Winter months. Upper Assam. 1875.

V. testacea, Rchb. fil. Syn., *Aërides Usightianum*, Lindl. (Bot. Mag., t. 5138); *A. testaceum*, Lindl.; *Vanda parviflora*, Lindl.—A very distinct and pretty species, which, however, at all times has been a rare plant in collections. Leaves strap-shaped, oblique and bilobed at the apex, with a small sharp point between the obtuse lobes. Raceme erect, simple, longer than the leaves. Sepals and petals about equal, ovate, and soft apricot yellow in colour. Lip three-lobed; side lobes joined to the foot of the column; middle lobe somewhat cuneate, obtuse, and again three-lobed in front, bearing several elevated ridges on the disc. Colour rich violet and lilac. Spur short and conical. June, July. Ceylon and on the Lyamally Hills, Hindostan. 1843.

V. suavis, Lindl. (fig. 30). (Bot. Mag., t. 5174). Syn., *Vanda suaveolens*, Bl.; *Vanda tricolor*, var. *suavis*, Rchb.—This superb plant is now a well known and much appreciated species. Leaves channelled, lorate or strap-shaped, gracefully recurved,

Fig. 30.—*Vanda suavis*.

oblique at the apex and toothed, deep green. Raceme lax, shorter than the leaves, bearing seven to fourteen large deliciously fragrant flowers. Sepals and petals spatulate, reversed or twisted at the base, china white, beautifully streaked and spotted on the inside with rich purple. Lip three-lobed, deep violet or purple; the lateral lobes paler, erect and rounded. April to July. Java. 1847.

V. sawis, Lindl., var. *Hrubyana*, Rchb. fil. (Flore des Serres, t. 1604-5).—General habit of the normal form, but somewhat more robust. Flowers very large. Sepals and petals twisted at the base, china white, profusely blotched and streaked with confluent spots of red and dark purple. Lip large rosy purple. April to July. Java.

On page 173 the date of introduction of *Aërides Lobbii* Ainsworth was inadvertently printed 1818; it should have been 1878.

ARAUCARIA IMBRICATA CONES.

IN answer to your correspondent "T. C." I beg to say that I have just collected 195 seeds, which I believe to be good, under an *Araucaria imbricata*, such as I have sent for your inspection. I have raised plants from the seed that has been grown here. The *Araucaria* has coned here for several years. One tree at this present time has twenty-five cones on it about the size of a large Melon. We have one tree growing clusters of male catkins all over it. I should say there are from thirty to forty clusters. Mice are very fond of the

Araucaria seed. I have not seen the *Araucaria* having the male and female variety on one tree.—EDWARD COVENY, *Gardener, Kenfield Hall, near Canterbury.*

[The seeds received are very fine, sound, and good.—EDS.]

PERHAPS it may be interesting to the numerous readers of the Journal to know that the *Araucaria* does mature its seed in this country. Here (Old Warden Park, Beds) we have two good specimens about 30 feet high and well furnished. They have been planted upwards of forty years. We have both the male and female variety. Herewith I send you a cone from the male tree; I also send you seed just shed from the female tree, which has borne seed on several occasions. The seed-bearing cones are large and globular—as large as medium-sized cocoa nuts. I would have sent you one, but they are at the top of the tree and consequently difficult to get at. These trees by some people are called "monkey puzzlers." They are not only monkey puzzlers but man puzzlers also; their prickly nature prevents any very close acquaintance.—G. R. ALLIS.

[The male cone received is 7 inches in length and 2 inches in diameter. Some of the seeds are sound and well matured.—EDS.]

BISHOP AUCKLAND HORTICULTURAL SOCIETY'S SHOW.

THIS Show was held on the 30th ult. in the beautiful grounds of Auckland Castle, kindly granted for the occasion by his Lordship the Bishop of Durham. This Society has long held a high position in the north, whilst for attendance at its shows it would rank with any Society in England, as much as £1100 having been taken in one day in shillings. For miles round the Exhibition is looked forward to as the great gala of the year, and scores of special trains enter the town heavily laden with visitors. The locale of the Show is good, whilst the promoters have always endeavoured to produce a good prize schedule; and it is much to be regretted that the last two exhibitions were held under the disadvantages of bad weather, and as a consequence the schedule this year has been curtailed.

In fruit and cut flowers perhaps the Society have never held such a successful show, and the prizes were strongly competed for; indeed the fruit was much superior to the display at the International Show at Carlisle last year. The collections were arranged in three marquees. We think it would have been much better had the marquees run parallel to each other and the ends taken out, and greater space and effect would have been given and better facilities would have been afforded for judging.

PLANTS.—These have always been both extensive and superior, but this year they fell off very much in numbers. The Society's prize of £10 for six stove and greenhouse plants only brought out two competitors. First Mr. J. Wilson, Normanby Hall, Middlesbrough, who staged fine examples of *Dipladenias amabilis* and *Brearelayana*, *Allamanda Hendersonii*, *Ericas* *Eweriana* *superba* and *obata*, which were both fresh and good, and a fine *Phenocoma prolifera* *Barnesi*; and second Mr. Noble, Woodhorn, Darlington, whose best plants were *Lapageria rosea* and *Clerodendron Balfourianum*, very good.

In the class for six handsome-foliage plants there were four competitors. The plants were remarkable for good culture, and caused the Judges some trouble in awarding the prizes. First honours eventually fell to Mr. Noble for fine and well-coloured examples of *Crotons* *Johannis* and *interruptum*, *Dasyliiron serratifolium*, *Areca Verschaffeltii*, *Yucca aloifolia* *variegata*, and *Cycas revoluta*. The second prize went to Mr. Niel Black, gardener to Mr. Pease, Southend, Darlington; and the third and fourth to Mr. Westcott, Raby Castle; and Mr. E. Lazenby, Woodside, Darlington, in the order named.

In the class for twelve stove or greenhouse plants with fine foliage, or Ferns, in pots not more than 14 inches in diameter, there was a fine display, the first prize going to Mr. Noble, who staged excellent specimens. Mr. Westcott, Raby Castle, secured the first prize for six exotic Ferns with fair examples of *Davallia Mooreana*, *Nephrolepis davallioides* (a fine plant), *Cyathea dealbata*, *Dicksonia squarrosa*, *Adiantum trapeziforme*, and *Davallia polyantha*, fine. Mr. Noble had the same position in the class for six British Ferns; and Mr. Short, Hummersknott, for six *Lycopods*, the latter very good.

Mr. Westcott secured the chief prize for two Orchids with *Vanda tricolor* and a magnificent example of *Peristeria elata* with three spikes and fifty flowers expanded. Mr. Noble had the second prize, his noteworthy plant being a fine example of *Miltonia spectabilis*.

Zonal Geraniums have long been a leading feature at Bishop Auckland. Mr. Short won the first position in the class for six plants in 10-inch pots with floriferous examples, but trained very

flat. Mr. Henry Johnston, Elmridge, Darlington, was placed second with fresher plants, but not so well flowered.

CUT FLOWERS.—For twenty-four Dahlias the first prize was £5, and such a display (eighteen stands) was forthcoming as has never before been seen at Bishop Auckland. Many of the flowers were very large but a trifle coarse; the recent rains had no doubt made them outgrow themselves. First honours were secured by Mr. Boston, Moss Spring Nurseries, Bedale; his best flowers being *Criterion*, *James Cocker*, *Henry Walton*, *Countess*, and *New President*. Messrs. Edwards & Sons, Nottingham, were second; Mr. Henry Clarke, Rodley, Leeds, third; and Mr. J. Walker, Low Fell, fourth. The first prize for twenty-four Hollyhocks, dissimilar, fell to Mr. Thompson, Newcastle, a successful exhibitor of them. The first for twenty-four Roses to Mr. H. Frettingham, Beeston, Nottingham. The second-prize collection of Messrs. R. Mack & Son, Catterick Bridge, York, contained fresher flowers, but were somewhat deficient in size. Mr. Thompson, Newcastle, secured the first prize for nine *Gladioluses* with fine spikes of good varieties.

Bouquets were numerous and excellent. Fifteen hand bouquets were exhibited, thirteen of them being good, the first prize falling to Miss Atkinson, Sunderland; the second to Mrs. Cramont, Sunderland. Bridal bouquets were nine in number, Mrs. Cramont winning the foremost place with a bouquet in which the white *Lapageria* and *Pancratiums* were used with fine effect margined with *Adiantums*.

FRUIT.—This was the greatest feature of the Show; the quality was excellent, and the entries were numerous. For a collection of eight dishes there were four competitors. The first prize fell to Mr. McIndoe, gardener to J. W. Pease, Esq., Hutton Hall, Guisborough, with fine examples of Muscat of Alexandria and Black Hamburg Grapes, large and well shouldered; *Violette Hâtive* Peaches; *Bryanston Green* Gage Plums, very large; *Moor Park* Apricots, fine; *Brunswick* Figs, *Colston Basset* Melon, and *Elruge* Nectarine. Mr. Wallace, Kirby Hall, Yorkshire, was placed second, his best dishes being *Buckland Sweetwater* and *Black Hamburg* Grapes, and *Diamond* Peaches; and Mr. Westcott third with a good collection.

For six varieties of Grapes Mr. McIndoe was again first with *Duke of Buccleuch*, very fine; *Madresfield Court*, *Barbarossa*, *Waltham Cross*, *Canon Hall* Muscat, and *Black Hamburg*. Mr. Westcott was placed second; his Grapes were excellent in colour and beautifully finished, but lacked the size of the first-prize collection. The *Raby Castle* Grapes included *Black Hamburg*, *Muscat of Alexandria*, *Foster's Seedling*, *Gros Colman*, and *Golden Champion*. Those who write and speak disparagingly of *Duke of Buccleuch* and *Golden Champion* Grapes ought to have been at Bishop Auckland, to have been satisfied of the superior quality of those Grapes. They were indeed fine and a credit to both raiser and cultivators. For two bunches of black Grapes the chief prize fell to Mr. Brown, Bishop Auckland, with *Black Hamburg*, finely coloured and of good size of berry and bunch. For two bunches of Muscats Mr. McIndoe was again first; with fine examples, and Mr. Wallace second; whilst for two bunches not *Black Hamburgs* Mr. McIndoe was first with *Madresfield Court*; and Mr. Bruce, Chorlton, Manchester, second with *Lady Downe's Seedling*. For two bunches of white Grapes, not Muscats, Mr. McIndoe was first with *Golden Champion*. Three Pines were shown, the first prize going easily to Mr. Westcott, *Raby Castle*, with a good fruit of *Charlotte Rothschild*.

Peaches were a grand display of nineteen dishes, the first prize going to Mr. Daglish, Alnrough, with, apparently, *Lord Palmerston*; Mr. McIndoe being second with *Violette Hâtive*, which we were surprised the Judges did not place first, so fine were they in size and colour. Nectarines were fairly good, the first prize going to Mr. Wrather, gardener to E. Pease, Esq. Ten dishes of Apricots were shown, twenty-one dishes of Pears, and sixteen Melons. Dessert Apples and kitchen were also numerous and excellent, The Worcester Pearmain Apples with which Mr. Witherspoon won the first prize in the dessert class were greatly admired for their splendid colour.

VEGETABLES were remarkably fine and extensively exhibited. Mr. McIndoe taking the first prize for the collection of eight varieties, and first for a collection of Potatoes; also first for a *Cucumber* named *McIndoe's Verdant Green*, a variety of much promise.

Classes were provided for those who do not employ a gardener, and contained mostly the exhibits of working men in the district. These were indeed commendable, more particularly the vegetables, which received great eulogiums from the public. The Society is arduous in endeavouring to promote a taste for gardening amongst the working classes, and the results are certainly very gratifying.

Among exhibits not for competition we noticed superior examples of *Vick's Criterion* Tomato from Mr. Jackson, Kirkleatham; also splendid pods of *Culverwell's Autumn Prolific Red*, many of them being 6 inches in length. Messrs. Little & Ballantyne, Carlisle, exhibited a valuable group of choice and rare Conifers, including their new drooping *Wellingtonia*.

The Exhibition was well managed by Mr. Hendy the Secretary,

Mr. Sibbald the Superintendent, and an active Committee, all of whom discharged their duties with much tact and courtesy.

NOTES AND GLEANINGS.

WE find from a prospectus we have received that Mr. Laxton, who is so favourably known as a hybridist and the raiser of many excellent Peas, Roses, Strawberries, Geraniums, and other garden plants, is about to establish AN EXPERIMENTAL GARDEN in which to carry on the work of hybridisation in which he has already been so successful. In his prospectus Mr. Laxton says, "The plan has already received the approval and concurrence of many scientific horticulturists, agriculturists, and botanists. The whole time, experience, judgment, zeal, and energy of Mr. Laxton, who has been so many years successfully engaged in cross-breeding, selecting, and raising new fruits, vegetables, Roses, and other flowers and plants, will be brought to bear, and as the garden will also to some extent fulfil the only practicable objects of the mis-named acclimatisation societies of other countries, as applied to the vegetable kingdom, it is confidently anticipated that the proposal will meet not only with the approbation but the material support of all interested. It is desired as far as possible to make the garden self-supporting; but as experiments in horticulture and agriculture are always costly, and, although frequently precarious in their results, generally conduce somewhat towards the public weal, it will hardly be considered inappropriate that the means should be at least partly provided by the public. For the purpose of successfully carrying out the plan endeavours are being made to secure two or three acres of good staple garden land with a limited amount of glass in a central and sheltered situation, for which a moderate capital and some choice stock will be necessary. Donations in furtherance of the objects in view will be received by Mr. Thomas Laxton, 53, Tavistock Street, Bedford, who hopes also, so soon as a suitable site can be procured, to receive contributions of plants, stock, &c. The terms of subscription with regulations and full particulars will shortly be issued. The privileges to be accorded to subscribers will include a priority in the distribution of all novelties raised at or secured by the establishment, and a right to a copy of the reports of the work carried on in the garden, as published from time to time, and to a share of the surplus plants, seeds, &c." We wish Mr. Laxton every success, and we have no doubt that if he has the opportunity he will add very considerably to his other achievements in this branch of horticulture.

— WE are glad to learn that the ISLE OF THANET FLOWER SHOW, held on the 31st ult. in the grounds of Bromstone Park, kindly lent by G. E. Hannan, Esq., was a successful one, and was attended by a great throng of visitors. Plants, flowers, fruit, and vegetables were alike good and creditable to the several exhibitors. The arrangements were complete and excellent, and reflected credit on Mr. C. D. Smith, the Honorary Secretary, and the other officials of the Show.

— THE late excursion of the NORTHAMPTON NATURAL HISTORY SOCIETY to Rothwell, Rushton, and Lampport proved, says the "Midland Counties Naturalist," a very enjoyable one. The party first visited the gardens and grounds of Rushton House, in which is situated the Triangular Lodge where the conspirators met to concoct the gunpowder plot. The wilderness used to be the habitat of the Fly Orchis, but this was searched for in vain. Rothwell Church and Market House were then visited, the *miserere* seats in the former being very curious. After a pleasant drive through the Harrington Valley and Orton to Foxhall, near which occurs the almost sole piece of bogland left in Northants, the botanical section eagerly searched over this ground, which yielded among other plants *Pinguicula vulgaris*, *Eriophorum angustifolium*, *Carex pulicaris*,* *C. stellulata*,* *C. flava*,* *C. fulva*,* *Carduus pratensis*, *Pedicularis palustris*, *Pimpinella magna*, *Gymnadenia conopsea*, *Orchis latifolia*, *Ophioglossum vulgatum*, *Molinia caerulea*,* *Triodia decumbens*,* *Valeriana dioica*, and a very rare plant, *Blismus compressus*,* In the hedgerows nearer Mosely Wood *Rosa tomentosa*, *R. micrantha*, and *R. Doniana* occur. Rejoining the photographic section at Foxhall the party proceeded to Lampport, noticing on the way *Festuca Myurus*. At Lampport the grounds of Sir Charles Isham afforded some pleasant rambles, the rockeries being covered with some interesting alpine plants. The rectory pond is said by Rev. J. M. Berkeley to yield *Acorus calamus*. [Plants marked thus (*) are not included in "Topographical Botany."]

— A CORRESPONDENT writes:—"At this season of the

year the labour of sweeping becomes a serious matter where there is a large garden. Can you inform me whether there is any MACHINE FOR SWEEPING LAWNS AND PATHS, which would either gather up the rubbish as the mowing machine does, or even sweep it into lines as the machine used in the London streets does?" [Is not this worthy the attention of some enterprising horticultural engineer?—EDS. J. OF H.]

— IN another column Mr. Luckhurst adduces examples showing the importance of SHELTER FOR FRUIT TREES. We may add another instance that recently came under our notice of a splendid crop of Apples, the result in a great measure of a sheltering belt of forest trees on the north side of the orchard. This fruitful young orchard is at Wimbledon, and belongs to Sir Henry W. Peek. Many of the Apple trees are crowded with fruit, and afford a striking contrast to thousands of trees that in other places are barren. Since so much is written on the pruning of trees it may be mentioned that for two years the trees referred to have not been pruned at all, unless the removal of an occasional branch in its entirety can be termed pruning, and the trees are as handsome in form and fruitful in character as can be desired.

— A MEETING of the creditors of MESSRS. W. ROLLISSON AND SONS of Tooting was held on the 27th ult. at No. 8, Old Jewry, E.C., when a trustee was appointed. The meeting was largely attended, and at the close the chairman remarked that much sympathy had been evinced by the creditors present for Messrs. Rollisson whose business is still being carried on, and it is confidently hoped that an arrangement may be arrived at whereby the uninterrupted continuance of the firm, which has now existed for nearly one hundred years, will be ensured.

— IT is with much regret we announce the DEATH OF MRS. OSBORN of the Fulham Nursery, widow of the late Mr. Thomas Osborn, and mother of Mr. Robert Osborn, who is by this sad occurrence left with the sole responsibility of the business. Mrs. Osborn died on Friday last, the 30th of August, at the age of sixty-one, after having for the last six months been entirely confined to the house.

NOTES ON VILLA AND SUBURBAN GARDENING.

THE latter half of August has been excessively wet in the neighbourhood of London, if not pretty general throughout Europe. The barometer has risen during the past few days, which gives us hopes of a change to drier weather which is much needed. Flower beds are not so gay as we are wont to see them on the 1st of September. Geraniums have grown coarse, while many other plants are looking somewhat weedy. It has been a fine time for the kitchen garden crops, and the winter supply of vegetables has made rapid progress; the only drawback is that the heavy rains have in many places, especially on hillsides, washed deep holes in garden paths, involving extra labour in levelling and rolling.

The various seeds that were advised in a former calendar to be sown have germinated sufficiently, so that there promises to be an abundance of every necessary to carry us through the winter. Myriads of seedling weeds have also made their appearance, these we shall take an opportunity of destroying by running the hoe through them on the first dry and warm days. The spring-sown Onions are quite ripe and have been pulled and laid to dry. As soon as sufficiently dry they will be strung together in small quantities and hung up. We know of no better way of keeping them, for frost and dry cold winds do not appear to injure them. Look over Potatoes that have recently been taken up, for we fear there will be loud complaints about the disease; after lifting we find several diseased tubers amongst ours. Make the last sowing of Lettuce for this season of the Bath or Brown Cos to withstand the winter, which will give tender and crisp Lettuces next May, and prick-out earlier crops a few inches apart on a warm rich border, that they may be lifted in the course of a few weeks and placed under protection in frames, &c. Thin Turnips before they grow overcrowded. These ought to be plentiful and good this autumn; the heavy rains have prevented the fly attacking them as much as ordinarily.

The propagation of next season's bedding stock must now for the present absorb our attention, and the sooner the cuttings are now taken off and inserted the greater is the chance of success. Geraniums of all kinds are easily detached, but care should be taken not to disfigure the beds. It is a very good plan to allow the cuttings of Geraniums after they have been made to lay for a few hours to heal the wounds caused by separation. By exposure for a short time the sap partially dries up, and a callus is the quicker formed with less risk of decaying. Place the cuttings of Geraniums thickly in shallow boxes, which are usually made from 2 to 3 feet long, 9 inches to a foot wide, and from 4 to

6 inches deep. In this manner great quantities can be housed during the winter, and can be potted-off singly during February; but where there are no boxes, pots of all the smaller sizes answer equally well. Five cuttings may be placed in a 4-inch pot, a few more in the next size, and so on. After rooting takes place very little watering should be given them or they will damp-off.

Cuttings inserted thickly now of Coleuses, Iresines, and the various Alternantheras will, if placed in a warm close temperature, strike freely and make a stock to supply abundance of cuttings during spring, which is the best time to propagate the summer supply of these fine-foliaged plants. Heliotropes, Ageratums, Petunias, and Verbenas may be all increased in the same way, allowing plenty of air when they are found to be established. It is too soon yet to insert cuttings of Calceolarias. Notes on them will appear later on.

Repot show and fancy Pelargoniums that have their growths fairly started, into pots a size smaller. In order to do this the ball of old soil should be shaken out and some of the coarse rough roots considerably reduced, using a good staple loam with a portion of decayed hotbed manure, leaf soil, and silver sand. Give Cinerarias another shift, the forwardest may be placed in their blooming pots for producing an early display. Chrysanthemums are growing fast, and will require the help of liquid manure to maintain the foliage of those plants that are root-bound and have exhausted the soil. The bloom buds are also to be seen, and we have commenced "setting" the blooms, or in other words dis-budding. On examination a flower bud may be seen in the midst of three or four young growths all apparently about to start into growth at one time. If these growths are removed with the point of a knife the bud will swell and eventually make a large flower, but if the growths are left the central buds perish and the flowers from the surrounding growths are much smaller and later. Make secure all growths to prevent the winds from injuring them, and attend daily to the various modes of training the specimens.

The stock of Dutch bulbs may now be ordered. After potting place them in the open ground under a cover of a few inches of cocoa-nut fibre. By no means place them under stages or where there is any drip, which will cause them to speedily decay. In vineries that have Grapes fully ripe and hanging it will be necessary to watch for decaying berries. It is almost impossible with the late damp weather day after day to keep the berries from moulding; when they are seen remove them promptly before they do injury to others.

Many of our earliest outdoor fruits now require harvesting. The wasps and large blue flies are very troublesome, making small holes in the sweetest varieties, which allow the rains to collect and cause decay. All fruit should be carefully hand-picked and carried to the fruit room, those damaged to be placed for immediate use. Of Pears we have a fair crop, and have gathered Williams' Bon Chrétien, which is always best gathered at two or three different times. By this plan the supply of Pears lasts longer. Peaches and Nectarines on walls are ripe and must be gathered daily for the table. Any fruit not fully exposed to the light should have the leaves pulled away from it, and the trees themselves should be kept tolerably thin and free from breastwood.

WORK FOR THE WEEK.

KITCHEN GARDEN.

WHERE Lettuces are required very early in spring a warm situation should be chosen with a southern aspect; the ground should be well drained and the soil light, rich, and firm. The seed should be sown in rows 9 inches apart in such a portion of ground as can be covered with frames when the weather sets in cold and wet. The best varieties for this sowing are Early Paris Market and Commodore Nutt, a compact very close-hearted kind, which may be sown in rows 6 inches apart. A bed of Lettuces should be sown in a sheltered situation at the close of the first or beginning of the second week in this month, for standing the winter and for transplanting in spring. Plant at once a good breadth of early Cabbages as advised in a former calendar. Sow a little more Cauliflower seed about the 7th to the 10th inst., which will afford plants for transplanting into frames or in front of a south wall in November. Plant at the foot of walls with south or east aspects Endive from the latest sowings. Sow a good breadth of Radishes, none being better than Wood's Frame and French Breakfast. From the moisture and comparative coolness of the late summer and autumn, Radishes sown now are very tender and good and generally esteemed. Plant out a good breadth of Lettuces from the July sowings. If the autumn be mild they will come in useful. Tie-up Endive and Lettuce in dry weather, and earth-up Celery, but afford moderate earthing only to crops that will not be required for use for some time yet, as earthing a little at a time is not calculated to promote the vigour of the plants. A dusting of the plants with soot early in the morning whilst the leaves are wet with dew will do much to ward off the fly, to invigorate the plants, and to drive away worms and slugs. Crops of winter Spinach must not be left too long without thinning, doing it in the first instance to 6 inches apart, and ultimately to

12 inches, every other plant being drawn at the second thinning and the leaves picked for use, which will save gathering from the permanent plants for some time. Keep the surface soil well stirred in order to promote free growth and cleanliness. The earliest crops of autumn Onions should be thinned to 3 inches distance apart in the rows, and every alternate plant may be afterwards drawn for spring use. A sowing may yet be made of the Tripoli Onions, and if bulbs are wanted early in summer make a sowing of the Queen in a warm situation but open, and it will be ready for use long before the Tripolis.

HARDY FRUIT GARDEN.

Fruit trees this season have required more than the usual attention in stopping the shoots, owing in a measure to the lightness of crop and to the prevalence of rains. Late summer and autumn growths must be restrained, as they only retard the ripening of the fruit and impair the vigour of the buds for future bearing. Let in, therefore, plenty of light by stopping back the laterals to one bud and the extensions of pyramids to about three or four; but if they have formed the terminal bud at a not greater distance than six or eight joints from the last stopping, and extension being wanted, do not stop them. The extension of Pears, Plums, and those fruit trees against walls producing their fruit upon spurs should be trained-in their full length if there be space, keeping the laterals closely stopped at one leaf. Peaches and Nectarines will still require attention in shortening the wood to about 12 inches for next year's bearing, laterals being pinched at the first leaf and removing superfluous wood altogether. Any fruit overhung by foliage must have the latter turned aside or be shortened so as to expose the fruit to light and air, or there will be a deficiency of colour and flavour. Cut out this year's bearing wood as the fruit is cleared. Those contemplating the lifting of unfruitful or unhealthy trees in autumn to renew old worn-out trees or the planting of new walls, should at once set about the preparation of compost for the purpose. Good loam neither heavy nor light taken from a pasture 4 to 6 inches thick and stacked in rather narrow ridges will with an inch layer of old mortar rubbish between each layer of turves, and if marl can be had an equal thickness to that of lime rubbish, form an admirable compost for all kinds of fruit trees. The making of new borders should be at once proceeded with so as to have the soil ameliorated before the time for planting arrives. The border should be well drained so as to prevent water lodging nearer the surface than 3 feet 6 inches, better 4 feet, and if the subsoil be wet and likely to induce late growths it will be more economical to concrete the bottom of the border than to allow the roots to pass into it, for no attention to pinching and manipulation of the heads of the trees will induce fruitfulness, or only for a short time, when the trees are unfavourably circumstanced at the roots. Rubble should be placed 9 inches to 12 inches deep for drainage, and over this place 2 feet 6 inches depth of compost. In some soils drainage only needs to be done, with the trenching of the ground 2 to 3 feet deep, but a little care bestowed upon the preparation of the border often saves much after disappointment and expense.

Strawberries that are to be kept for future crops should now have all runners, and such of the old leaves that come readily away with them, cut off, but avoid the weakening process of divesting the stools of foliage. The stools with their healthful foliage should be about 2 feet distance apart, or the stronger growers 2 feet 6 inches. After clearing away all weeds, mulch at once with any partially decayed manure not less than an inch thick. The removal of the runners will admit light and air to the crowns, and the mulching will keep the soil moist, bringing the roots to the surface, which assist the formation of bold crowns. New plantations must have the runners removed and all weeds kept under, they, too, being the better of a mulch of manure now instead of later in the season, when it can contribute little to the plants' advantage, but given now it aids in the formation of crowns. There is yet time to plant runners with a prospect of fruit next season, but those well rooted in pots must be selected, and the soil made firm about the balls. Some defer planting until spring. In that case the runners should be planted out now rather thickly in nursery beds, and have water until established.

Strawberries in pots for forcing will now be well established and require liberal supplies of water. If the plants grow vigorously do not give them liquid manure, but those that are weakly afford liquid manure twice a week. Remove all runners as they show, and loosen the surface of the soil near the sides of the pots, so as more thoroughly to insure the moistening of the ball. Runners well established in small pots may yet be potted for late forcing. For particulars of potting see former calendars. As the plants grow—increase in foliage—set the pots wider apart. If red spider show itself hold the plants inverted separately with one hand, and with the other dust the under side of the leaves with soot from a dredger.

FLOWER GARDEN.

Although the summer has been generally favourable for the growth of summer bedders, herbaceous plants have been and still are more than ordinarily attractive. At one time there was a dread of the modern system of flower gardening pushing a most

interesting and beautiful class of plants out of cultivation; but there is now nothing to fear on that score. Herbaceous and alpine plants in the mixed border are more appreciated than ever. Such a border should include all flowers, hardy or otherwise, available for outdoor decoration, for, apart from the interest of mixed collections, a variety of flowers is afforded for cutting. The herbaceous or mixed border to the real lover of flowers is far more satisfying (for at almost every step something of fresh interest and beauty reveals itself), than masses of colour, brilliant and effective as they may be, which are taken in at a glance, and producing little more than a momentary pleasure.

There are now several distinct styles of flower garden decoration—namely, parterre, in which the beds and their adjuncts combine to form a picture of beauty by the employment of flowering plants; subtropical, or that style admitting of bold-foliage plants disposed in groups with isolated specimens, than which no style in suitable situations contributes more to gardenesque effect. The latest style—carpet bedding, is perhaps the most popular, and when well done is very effective. That it is a step in the right direction is best inferred from the fact of its increasing in public favour, not the least of its attractions being that an otherwise meaningless bed may by internal tracery be transformed into an object of art in design and beauty. There are also Italian gardens—a combination of device in Box, grass, gravel, statuary, vase, fountain, formal shrubs and plants; and there is the Rose garden, essentially English, as is also the mixed garden, which two are best calculated to supply the requirements for flowers of a majority of the owners of private gardens. We introduce this subject now as the time is near when alterations are usually made, and often without consideration being given to the purpose they are intended to serve. If a garden is intended to afford objects of interest in variety and succession then we have no hesitation in pronouncing in favour of the mixed style—flowering, evergreen, and deciduous shrubs, borders of herbaceous, alpine, and bulbous plants, with masses of the choicer or statelier and profuse-flowering plants, such as Pansies and Violas, Carnations, Dahlias, and Roses. If a grand picture of limited duration is coveted, then the other styles come in for their share of consideration.

The propagation of the various kinds of bedding plants must be pushed on as fast as possible, so as to have them well established before winter. If a sufficient stock of *Pelargoniums* be not yet raised lose no time in inserting cuttings—four in a 4-inch pot; also secure a sufficient quantity of *Heliotropes*, *Verbenas*, *Ageratums*, *Lobelias*, *Iresines*, *Mesembryanthemum cordifolium* variegatum, &c. These need not be propagated in great numbers, as they strike readily in spring; but a sufficient quantity of store pots should be secured so as to supply the requisite cuttings in spring.

Annuals for Spring-Flowering.—Sow now seeds of the following annuals in moderately rich light soil, either where they are to remain for flowering or for transplanting:—Sweet Sultan, purple, white, and yellow, and Cornflower (*Centaurea Cyanus*) for an early bloom of those of those desirable flowers for cutting; also *Silenes*, Sweet Alyssum, *Eschscholtzias*, *Virginian Stocks*, *Saponarias*, *Nemophilas*, *Calandrinia umbellata*, *Collinsias*, *Candytufts*, *Gillias*, *Kaulfussias*, *Lasthenia californica*, and *Erysimums*.

The work of keeping gardens neat is now considerable, as the wet has expedited the growth of weeds, which must be kept under, and trees are casting more or less of their foliage, which must be swept up frequently so as to keep up a good appearance as long as possible. Pick off bad flowers and leaves from the plants in beds, keeping the lines distinct by stopping, &c., running the mowing machine over the grass frequently, keeping the edgings neatly cut, and rolling the walks well, which go a long way to make a place enjoyable. Complete the clipping of Yew and Privet screens; and any *Arbor-Vitæ*s, *Irish Yews*, *Junipers*, or others of the *Coniferae* that are liable to open in the middle tie up to prevent breakages and to maintain the symmetry of the specimens.

PLANT HOUSES.

Greenhouse.—Flowers will soon become scarce outdoors; provision must therefore be made to meet the demand for cut flowers, &c., by a supply of suitable plants under glass. *Heliotropes* if grown as advised will be in good growth and advanced for flowering, but all blooms showing before the middle of the month should be pinched-out, and the plants well supplied with liquid manure.

Mignonette must have every encouragement in keeping it duly watered, and shifting the plants into larger pots as they require it. They should be placed under glass before heavy rains occur, keeping them near the glass, affording neat supports, to which the shoots must be secured as they are liable to snap. Keep a sharp look-out for green aphids, and at once destroy it with tobacco water, or fumigate, but it must be done moderately or the foliage will be scorched. *Mignonette* sown in August must be thinned to three or five plants in a pot, and be kept near the glass and not overwatered. For affording a succession of bloom seed may yet be sown in 3-inch pots, duly thinning the plants when large enough to handle, and when the roots are matting around the sides of the pot shift into 6-inch pots. They are very useful in spring and early summer; but to have *Mignonette* in quantity

a pit should be planted with healthy plants from the August sowing, turning them out with the balls entire in a compost of turfy loam with a fourth part of well-decayed manure or leaf soil, and an eighth part in equal proportions of old mortar rubbish and pieces of charcoal not larger than a hazel nut, the surface being 18 to 24 inches from the glass, planting about 15 inches apart every way. There must be pipes for heating so as to maintain a temperature of 50° to 45°. An immense quantity of spikes may be cut through the winter until summer, keeping the spikes closely cut, as seeding soon ruins the plants. Air should be afforded abundantly in all favourable weather.

Tree Carnations should have all flowers removed and duly supplied with water, affording them weak liquid manure occasionally, and place them in a position where they will receive all the light possible, as upon a sturdy solidified growth depends their suitability for winter flowering. Pinks, too, intended for forcing must be encouraged to complete the growth and to firm it by full exposure. Epiphyllums are very useful and should have all the light possible, so as to ripen the growth, affording water only to keep the parts plump. They will flower satisfactorily in a greenhouse, but are the better of an intermediate house or a little warmth when making fresh growth.

Clematises.—These are fine when grown in pots for decoration, coming into flower with little forcing. Some of the best are Miss Bateman, The Queen, Vesta, Lucie Lemoine, Henry, Willison, Lord Lonsborough, Lady Lonsborough, Stella, Fair Rosamond, Countess of Lovelace, and Albert Victor. They should have a warm situation with a view to the thorough ripening of the wood, and though they must not be neglected for water too much is pernicious; therefore in very wet weather lay the pots on their sides.

Daphne indica will have completed the growth and must not be over-watered, which is one of the chief reasons why this plant is seldom seen in good condition. The freest-flowering plants are grafted, but cuttings of 4 to 6 inches in length may now be inserted singly in small pots in sandy loam and peat, placing them in a house with a temperature of 50° to 55° until they have formed a good callus, and then in a bottom heat of 75°, where they will root freely.

Hardwooded plants placed outdoors must not be allowed to remain exposed to heavy rains for any length of time, or the soil will be so saturated as to jeopardise the well-being of the plants. In cold localities it is not safe to trust them to the tender mercy of the weather after the middle of the month; indeed if the weather be wet it is best to place them under cover without further delay, as the tender-rooted kinds often perish from excessive wet.

TRADE CATALOGUES RECEIVED.

Charles Turner, Royal Nurseries, Slough.—*Catalogue of Bulbs, Seeds, and Strawberries.*

Thomas S. Ware, Hale Farm Nurseries, Tottenham.—*A.B.C. Bulb Guide and Select List of Perennials.*

Sir James W. Mackey, 23, Upper Sackville Street, Dublin.—*Descriptive Catalogue of Dutch Flower Roots.*

Osborn & Sons, Fulham.—*Catalogue of Hyacinths, Tulips, and other Choice Flowers.*

James Cocker & Sons, 82, Union Street, Aberdeen.—*Descriptive Catalogue of Dutch Flower Roots.*

Louis Van Houtte, Royal Nursery, Ghent, Belgium.—*Catalogue of Azaleas, Camellias, Rhododendrons, &c.*

J. Linden, Ghent, Belgium.—*Catalogue of Azaleas, Camellias, Rhododendrons, Palms, &c.*

James Vick, Rochester, N.Y.—*Illustrated Floral Guide, and Lists of Bulbs and Plants.*

TO CORRESPONDENTS.

* * All correspondence should be directed either to "The Editors" or to "The Publisher." Letters addressed to Mr. Johnson or Dr. Hogg often remain unopened unavoidably. We request that no one will write privately to any of our correspondents, as doing so subjects them to unjustifiable trouble and expense. Correspondents should not mix up on the same sheet questions relating to Gardening and those on Poultry and Bee subjects, and should never send more than two or three questions at once. All articles intended for insertion should be written on one side of the paper only. We cannot reply to questions through the post.

BOOKS (*M. J. T.*).—The "Journal of Botany," published by Hardwicke and Bogue.

DOUBLE CARNATIONS (*P. C.*).—We can only sympathise with you. Two double plants out of a hundred is a small per-centage for 2s. 6d., and after the trouble of raising them you have good reason to be disappointed.

DISCOLOURED LEAVES (*Flora*).—They are injured by thrips. Our correspondent wishes to know how green frogs are to be kept in winter.

PEACH TREES DISEASED (*A Subscriber*).—The trees are attacked with red spider. You must syringe the foliage frequently. We have known it effectually cured by standing saucers of ammoniacal liquor from the gas-works in various parts of the house.

BLACK MILDEW ON ROSES (*R. G. M.*).—We know of no application better than Fowler's insecticide or Gishurst compound for the "black blotch." The cause of it is generally poverty of soil or drought. A liberal supply of liquid manure will probably prevent its appearance.

BURNT EARTH FOR ROSES (*A Lover of Rose Shows*).—Burnt earth is an excellent addition to heavy soils. Some kind of "ballast" is burnt earth, but not all. "WYLD SAVAGE" has not tried the artificial manures referred to for the same reason as the one you submit—namely, not being able to obtain them in small quantities. If you roughly dig your soil, exposing it thoroughly to the influence of air and frost, it will become partially pulverised, and then if you can place a little lighter soil around the roots of the Roses when planted—a shovelful or two to each will do to expedite the emission of fresh roots—we think you will succeed in your object. A compost of burnt earth, decayed vegetable matter, and a liberal admixture of soot, say a quarter of a peck to each barrowful of soil, would be very suitable for the purpose recommended.

SCHIZOSTYLIS COCCINEA CULTURE (*C. K.*).—The plants should be planted in spring or early summer in good soil in an open but not highly exposed position in the kitchen garden, and in the autumn when the flower spikes appear pot the plants and place them in a light greenhouse, where they will continue flowering until Christmas. You have kept the Cyclamens too dry; they require a partial rest after flowering, but should always have the soil sufficiently moist to keep the roots and corns fresh.

FRUIT TREES FOR NORTH WALL (*W. R.*).—The Morello Cherry is the most suitable, but such Cherries as May Duke and Bigarreau Napoleon Cherries do well and afford a good succession. *Pears*: Jargonelle, Citron des Carmes, Williams' Bon Chrétien, and Marie Louise. *Plums*: Victoria, Jefferson, White Magnum Bonum, and Blue Perdrigon are all suitable.

GOOSEBERRIES FOR WALL (*M. J. Read*).—They succeed quite well as well as Currants. The best sorts for dessert are—*Reds*: Wilmot's Early Red, Scotch Nutmeg, Champagne, and Warrington. *Yellows*: Yellow Smith, Yellow Champagne, Broom Girl, Rumbullion, and Leader. *Whites*: Snowball, Crystal, White Champagne, Bright Venus, and Lady Leicester. *Greens*: Fitmaston Green Gage, Green Walnut, and Green Gascoigne.

RAISING FERNS FROM SPORES (*A Constant Reader*).—Drain a pot or pan well, place over the drainage the rough of the compost (sandy peat sifted), filling to within an inch of the rim with the sifted peat, mixing with the peat on the surface an equal quantity of silver sand, making the surface even and moderately firm. Afford a good watering, and when the soil has settled down brush the spores from the Fern fronds with the hand over the surface of the pot or pan and cover with a pane of glass, resting upon the rim so as to entirely cover it. Place in a cool house or frame for hardy kinds, a greenhouse or stove for exotics on a damp bottom, shaded from bright sun, and never allow the soil to become dry, but avoid making it sodden. In the course of about six weeks the surface will become green, that is when the spores vegetate; the pane of glass should then be tilted a little on one side and removed altogether when the fronds reach the glass.

STEPHANOTIS FLORIBUNDA (*Carolus*).—The cutting-off of all the foliage of your Stephanotis was a mistake, which, however, may not prove fatal if the wood is still alive and plump. Give water with care and moderation now and till the end of the year, keeping the plant in a temperature of from 50° to 55°. Prune in January, shortening the stout growth and cutting out all weak shoots, and by the end of that month or in February greater warmth of temperature and a free use of the syringe should induce an abundant free new growth, and when the plant is growing freely an occasional dose of liquid manure will do much good. When in bloom and throughout summer it may be removed to a warm greenhouse.

RHYNCHOSPERMUM JASMINOIDES NOT FLOWERING (*Idem*).—Overpotting is probably the chief cause of your plant not flowering. Small pots, well-ripened wood, and a moderate temperature, are three important points in the culture of this plant. Take your plant out of the hot-house at once to a sunny airy position in a greenhouse or orchard house, give only enough water from the present time till March to keep the foliage healthy, and keep the plant in the greenhouse where the usual winter temperature of 40° to 45° is maintained, thus letting the winter be a period of complete rest. In March cut off any bare old growth, and thin any that is crowded, shortening the remainder to induce a plentiful growth of young shoots, at the ends of which the flowers should appear. Just as growth begins shake out the plant from its large pot and examine the roots; if they are crowded in the soil and the drainage is good replace in the same pot, but if there is much soil without roots then remove it and repot in a size or two less, picking as much of the old sour soil from among the roots as possible, ramming hard some fresh sweet soil around the ball. As the growth makes progress give more water, but do not remove the plant from the greenhouse till the flowers fade, then turn it out of doors, standing the pot upon a bed of coal ashes in any open yet shaded nook, and keep it there till the autumn. Withhold water almost entirely from your Night-blooming Cereus during winter, take especial care it is not overpotted, and with a somewhat lively spring temperature you will obtain flowers.

SELECT CHERRIES FOR ESPALIERS (*Lady C. T.*).—The five best sorts of Cherries to be trained as espaliers for a supply of fruit from the middle of July onwards into August are Empress Eugénie, Governor Wood, Reine Hortense, Duchesse de Pallua, and Florence. The position you have chosen for the trees is an admirable one, well calculated to screen the blossom from cold wind.

LATE STRAWBERRY (*Idem*).—Frogmore Late Pine is an excellent late sort. A useful way to prolong the period of obtaining ripe fruit is to plant one bed in a position that is fully exposed to the sun, and another in the shade of a tree or building. By planting beneath the boughs of a huge old standard Pear tree we have been able to keep up our supply of fruit until the middle of August.

TRANSPLANTING CHRYSANTHEMUMS IN AUTUMN (*Idem*).—This may be done forthwith, or at any time till the plants are in full bloom. The latter period is usually thought preferable, because it admits of the summer flowers being kept as long as they are ornamental. If, however, your border can be spared then plant at once in dull weather, and thus accelerate the development of the flowers.

GLAZED POTS FOR WINDOW PLANTS (*J. D.*).—Provided the pots are well drained, and care is exercised in watering the plants so as to prevent the soil being soddened, plants will thrive well in glazed pots.

ROOF FOR A CONSERVATORY (*R. J. S.*).—If you use rough plate glass you can have it of any strength, and it will not injure the plants in the least.

It has often been recommended for ordinary glazing because of its strength and its prevention of scorching. You can use a gas stove in your conservatory provided you have a pipe communicating outside to carry off the vapours generated in combustion.

ORANGE TREE CASTING ITS FRUIT (*Miss W.*).—It usually arises from imperfectly ripened wood, the plants growing too vigorously. Afford them a light airy position in the warmest part of the house, and give no more water than to keep the foliage fresh. When the tree is starting into growth and flower afford water liberally, but avoid making the soil sodden. When in blossom impregnate the flowers. We think from the one planted out not flowering that the plants are too much shaded, and the atmosphere too cold and moist to ensure the ripening of the wood.

MALFORMED APPLE (*A. T. Waters*).—This is not new, although not common. It occasionally happens that the growing axis of a shoot is continued through a fruit or a flower, and the specimen you have sent is one of these.

DESTROYING BINDWEED (*R. B. B.*).—This is one of the most difficult of all weeds to eradicate. We know of no other means of keeping it in check than by the constant and persistent application of the hoe. If you never permit the plant to grow more than a quarter of an inch through the soil the roots will be gradually weakened, and the labour of hoeing will diminish yearly. The great point to aim at is never to allow it to form leaves; if you can manage that the roots will decay.

READ'S BOILER (*D. D. Cardiff*).—This useful boiler is best set outside of the house; if inside we fear you would experience some inconvenience by the dust and dirt that are inseparable from the management of the fire.

SCREEN OF TREES (—).—We should be glad to assist you, but we cannot say what the screen of trees is before the house at Herne Hill. Perhaps it is Black Poplar or Oriental Plane. Send a leaf if you can.

STRAWBERRIES AND RHUBARB (*Ecce*).—Two useful Strawberries are Vicomtesse Hericart de Thury and President. Let the Rhubarb remain until the leaves decay, then remove them and replant as you propose. The heavy showers to which your Fuchsias have been subjected are quite sufficient to account for the tubes of the white-sepal variety splitting, an evil to which it is peculiarly subject.

CLUB ROOT (*R. T.*).—The parent weevil is of a dusky black colour, with the breast spotted with white, and the length of the body one line and two-thirds. The ambury of the Turnip and Cabbage usually attacks these crops when grown for successive years on the same soil. This is precisely what might be expected, for, where the parent insect always deposits her eggs, some of these embryo ravages are to be expected. The ambury is most frequently observed in dry seasons. This is also what might be anticipated; for insects that inhabit the earth just beneath its surface are always restricted and checked in their movements by its abounding in moisture. Moreover, the plants actually affected by the ambury are more able to contend against the injury inflicted by the larva of the weevil by the same copious supply. Charcoal dust spread about half an inch deep upon the surface, and just mixed with it by the point of a spade, it is said prevents the occurrence of this disease. Soot, we have reason to believe from a slight experience, is as effectual as charcoal dust.

GROWING FIGS AND GRAPES TOGETHER (*H. E. W.*).—They may be grown in the same house, the roots of the Vines being a good distance apart, and the shoots trained rather thinly so as to admit light to the Figs beneath, which would need to be grown in pots, and then considerable cultural skill is required to secure satisfactory crops of both Figs and Grapes. We advise, in case of your deciding to grow both in the same house, to restrict the Vines to the larger side of the span, and have the Figs at the back trained to a trellis against the wall, restricting the roots to a border about 2 feet in width, and not allow anything upon the smaller part of the span. The house would be most satisfactorily and economically heated by hot-water pipes and a stove boiler fixed in a shed behind the house. Two rows of 4-inch pipes along the front and across one end would afford all the heat required; artificial heat, however, is not necessary to secure a crop of Grapes or Vines unless you require them early, and to secure two crops of Figs in a season.

SHRUB NOT FLOWERING (—).—The spray is not an Andromeda but, we think, an Arbutus, probably *A. laurifolia*, which does not flower until the plants attain a large size. Probably cutting the roots at a distance of 2 feet from the stem would check the growth and tend to earlier flowering. Judging from the spray forwarded us the shrub must be very handsome from foliage alone, and we should not be disposed to interfere with it in any way, allowing it to take its own time as to flowering, patience in such cases being often well rewarded.

VALLOTA PURPUREA AND VAR. EXIMEA (*A. Boyle*).—The dry bulbs should not have been kept without water until May, but ought to have been potted and kept moist, and placed in bottom heat in February or March to induce root-action, and that secured they would have pushed foliage strongly, which ought not to have been much advanced before the pots were gradually withdrawn from the hotbed and placed in a light airy position in a greenhouse, and kept well supplied with water until the growth was complete, and then enough to maintain the foliage fresh. The plant in the open ground we should now take up and pot. Turfy loam with a fifth of well-decayed manure will grow these plants perfectly, but we gave our plants a dash of buffalo horn manure at the last potting, and they evidently relish it, being finer than they ever were before. Only a twentieth part was used to turfy loam. Our plants are potted so that the base of the older bulbs only is covered with soil; but as we remove the offsets but seldom, only for purposes of increase, many of the bulbs are covered with soil, others about half, and some almost clear of it, and all do well. We prefer them with the base of the bulb covered with soil. We did not receive your Campanula.

ROSE FROM CANNES (*C. W. Cox*).—We are rather at a loss to name the Rose. It is not exactly Ophire though much like it. It much resembles an old Rose called Duchess of Mecklenburg.

NAMES OF FRUITS (*Thomas Holman*).—Orange Mispique. (*Lewins*).—Sweet Lading. (*Knutsford Subscriber*).—The Pear is Madame Treve, the Apple we do not know. (*W. H. W.*).—We will name your fruit next week. There is nothing the matter with the Grapes; we consider them very good to have been grown in a greenhouse, where, of course, they could not receive much artificial heat.

NAMES OF PLANTS (*C. K.*).—Flower apparently *Schizostylis coccinea*. Fern, *Nephrodium decompositum* var. *glabellum*. (*Triceps*).—We cannot name plants from leaves only. 1 is not a Eucalyptus, and 2 is an *Acacia* of

some sort, but we cannot tell which it is from the leaf, as the genus is a very numerous one. (*W. Hilloak*).—1, *Hieracium sylvaticum*; 2, *Stachys palustris*. (*John Davis*).—An *Epilobium*, but the specimen is insufficient to enable us to determine it. (*Edward Long*).—*Calceolaria scabiosaeifolia*. (*Jeune*).—1, *Berberis vulgaris*; 2, *Anthemis Cotula*; 3, *Eupatorium odoratissimum*. (*Conan*).—Your Lily is from Japan, and is the new variety of *Thunbergianum* which has recently been called *Batemanæ*. It is very beautiful and, we believe, very scarce.

THE HOME FARM:

POULTRY, PIGEON, AND BEE CHRONICLE.

THE CULTIVATION OF WINTER BEANS.

THE cultivation of winter beans is altogether so different from that of spring beans that we propose to treat of it separately, and this not only applies to the beans, but to the land upon which they are or may be most advantageously grown. Spring beans are identified in their growth with strong heavy land only, but not so with winter beans, because almost any loamy land in good tilth and cultivation will produce them in great abundance in favourable seasons. There is also another striking difference between winter and spring beans—the latter are far more subject to blight than the former, and are consequently a more speculative crop; and when we consider the variety of soils upon which the winter beans may be profitably grown, it in our estimation places them far in advance of spring beans for culture on the home farm. We shall have to refer to their cultivation under varying circumstances, not only as regards their growth as an individual crop, but also as a double crop in connection with other pulse, and also as a crop with vegetable produce in intermediate culture.

Although the winter bean may be grown with success upon dry loamy land with various subsoils, yet it is a question of climate as well as soil, for we find that the western and mid-land counties being subject in ordinary seasons to a greater rainfall than the eastern and southern counties, and consequently beans, either winter or spring sort, flourish better and are less subject to blight than in the drier counties. It often happens that a week of dry harsh weather from the east whilst the beans are in bloom is fatal to the crop, and this harsh east wind is peculiar to the eastern counties, whilst moist and rainy weather accompanied by a lower temperature more nearly represents the seasons peculiar to the western counties.

When land is intended for this crop it is well that it should be free from couch grass, and in order to save expenses in cultivation by horse labour it is best to have any couch forked out by hand which may be found in small separate bunches here and there. It is altogether unnecessary to incur heavy charges in horse labour in preparing the land, for in case the land is fairly clean one ploughing with harrowing and rolling will be quite sufficient to make the land firm at bottom and fine on the surface, which are practically the two leading points required in cultivating for winter beans. It is common now to drill winter beans, but formerly the plan was to plant with the dibble by hand, one man using two dibles, followed by women or boys to drop the beans, not more than two in each hole, and this is the best way to insure a regular plant. It is also best when a double crop of pulse is required. For instance, when winter vetches are drilled with the beans it is very difficult to adjust the quantity of beans and vetches, even when a few vetches are put in the drill at every turning on the headlands. The vetches usually will run much faster than the beans, and this causes an irregular and bunched plant, but in dibbling we insure a regular and even plant. The quantity of seed required will be two bushels per acre when drilled, but when dibbled $1\frac{1}{2}$ bushel will be sufficient, and when vetches are dibbled with the beans a half bushel per acre of vetches will be quite sufficient. When the winter beans are required as a single crop the distance between the rows may be 2 feet when dibbled, but 27 inches when drilled. We recommend the latter distance as best to secure the full advantage of interculture with the horse hoe. Winter beans usually stalk out and branch much wider than spring

beans; in fact, drilled beans always require most room. In all cases, either of drilling or dibbling, the distance between the rows is of great importance, because when the plants become crowded the free circulation of air and the action of the sun is excluded to a certain extent, and renders the crops far more susceptible to blight, and causes the blooms not setting so well nor will the pods fill so regularly as they should do.

It is of consequence to consider how this crop stands in the rotation, for although a crop of oats may pay as well as the beans the difference would be very great in the wheat crop whether it followed beans or oats, and much in favour of the beans. Although we have sometimes grown fine crops of wheat after oats upon the same style and rotation as grown in some parts of Lincolnshire and other counties on the fen lands, yet under ordinary culture upon the generality of soils the wheat will be much better after the beans, because we view it as a fallow crop, in the culture of which the land becomes aerated and mellow, and the falling leaf of the bean crop is considered to have a beneficial and fertilising effect upon a wheat crop following. Some of the best soils of strong loam in various districts are cropped with beans and wheat alternately, and some have been cultivated in this manner for a long period, and the land let subject to such a system of sowing fetches a higher rent in consequence. When this is the case it is, however, just a question which answers the best purpose—the winter or the spring beans. When it is intended to take a crop of roots in conjunction with winter beans the land should be clean and bouted up into ridges 3 feet wide, and a single line of beans planted in the centre of the ridges, and in this way we have taken a lesson from the market gardeners, who grow beans and cabbages in alternate lines. We first tried the plan of intercropping with roots about twenty-five years ago, and it proved very successful, our cultivation being, after setting the beans in the centre of the 3-foot ridge, to let it remain during the winter months. In the spring, as soon as the land would work freely, the horse hoe was used; we then drew a furrow with a one-horse double mould plough, into which the artificial manure was applied, and then horse-hoed again, and dibbled either mangold or carrots, seed or planted cabbages; the latter proved the surest and best adapted for the purpose. As soon as they have taken root well the land may be hand-hoed for the last time, and allowed to remain until the beans are fit to cut, which will be generally about the time of commencing wheat harvest, and sometimes a little earlier. When the beans are removed the land is horse-hoed between the roots, and this has a most beneficial effect upon the root crop, as well as clearing the land of any weeds which may have crept up in the lines of beans. The lines of beans being 3 feet apart we have found them yield much better than when planted closer, and in the same way the roots having so much rooting space they come very large, particularly if the manure for them has been applied liberally. We have frequently grown from 5 to 6 sacks of beans, and from 18 to 20 tons of mangolds per acre in favourable seasons, which must be considered a great produce as compared with a single crop. Cabbages do equally well and give a heavy crop, and are more certain to maintain a plant, because any crop to be reared from seed, like mangold or carrots, will always have to contend with insect enemies during their infancy. This method of double cropping only applies to the kinder and better soils, and is not adapted for strong clay land, strong land being most suitable for the growth of spring beans. When the beans are grown alone after the first horse-hoeing it is a good plan to harrow a single line across the rows of beans when the weather is dry, which will not only destroy the small weeds, but will break the shell or crust of the land around the plants and greatly facilitate their growth and the hand-hoeing which is to follow.

The best time for drilling or planting winter beans is about the middle of October, and it should be remembered that after the land is properly harrowed drilling answers best upon stale furrow, but planting succeeds best upon a fresh ploughed furrow, the land being properly harrowed and water-furrowed after planting.

Sometimes we have known winter beans planted in double rows 9 inches apart and 20 inches apart between the double rows. This plan is, however, better adapted for spring bean culture, because the hand hoes must work in the 9-inch space, and as winter beans branch out most they impede the hand-hoeing.

The cutting of winter beans early is of great consequence, and the best time is when the eye of the corn is turned black, the haulm being but little guide, as that will often be comparatively green, although the beans will be matured sufficiently for cutting. As, however, winter beans, particularly after a severe winter, grow very short, and are often podded close to the ground, we prefer to pull them by hand, and after being tied the sheaves stand several inches more above ground. The early cutting is of the utmost importance, because they will then take showery weather without the shedding of the corn by the shrinking and opening of the pods. In tying the sheaves we prefer tying with yarn, as the straw bonds do not answer all the purposes, as they are apt to break in stacking or in hauling to the machine at thrashing time. Formerly, instead of tying into sheaves at the time of cutting, it was the practice to set them up in loose state, tying the tops with a wisp of straw, and when dry then to tie into sheaves for stacking.

WORK ON THE HOME FARM.

Horse Labour has been lost to some extent owing to a succession of adverse weather for carting corn to stack or barn, and the same weather which prevents harvest work often renders horse labour of but little value upon the land. Now is the best time to sow trifolium, and it is often requisite when the land is not quite clean to scarify and then drag and harrow, and cart the weeds and stubble to a heap. This when decayed makes a good dressing for the pasture land, particularly if it has been put at the bottom of the pigsties, as it then comes out with the dung as first-rate manure. It has also the advantage, when the dung is allowed to accumulate, of keeping the pens drier and more healthy for the pigs, especially when the animals are fed mostly upon green food, for in such cases the portions of green food not eaten are trodden down, and so far serving the purpose of litter to some extent. When the accumulation in the sties becomes inconvenient, it will on removal be found to be some of the most valuable manure that can be made on the home farm. At intervals the horses will be engaged in cleaning and preparing the pea eddishes to be sown with wheat; and our plan is, first to rafter or half-plough the land, then scarify across the rafters, harrow and roll, and cart away weeds and rubbish to a heap, there to rot for future use. In some cases the horses will be ready to draw out manure from the farm premises on to the lea ground intended for wheat. We prefer to lay out manure on the clover leas instead of drawing it on to the peas or beans fallowed land, because on the lea ground the horses and carts pass over the land without injury by treading, &c. We, therefore, prefer to dress the land for wheat in those cases where it has been recently worked after peas or beans with guano, and in ordinary soils we have often obtained the best wheat of the season by an application of 3 cwt. per acre of the best Peruvian guano, and especially if the wheat is put in early, and the soil adapted for wheat culture, and the stronger the land is the more advantage it receives from guano. Our plan is to sow the guano broadcast, mixed with damp ashes to prevent its flying before the wind, and when sown upon the recently ploughed furrow and harrowed-in, the wheat may then be drilled without any injury to the young plants by the pungency of the manure, for it is never safe to drill guano with the seed. The odd horse will be engaged in horse-hoeing the stubble turnips; and in case these were sown after white oats, or the earliest cutting of wheat, they will now be forward enough to be horse-hoed, and hand-hoed also immediately after, for we have often had stubble turnips when sown after the earliest corn crops and when they have been drilled daily between the shocks of corn, had them sufficiently forward to furnish cover for the partridges on the 1st of September. Some say that September 1st is the latest period at which turnips should be sown in corn stubbles. When, however, they are sown thus late they do not give much food for sheep, unless they are allowed to run-up towards flowering in the spring; still, late turnips when sown after wheat may be ploughed under in the early spring for barley with the prospect of producing a full crop.

Hand Labour has been very various, the continuous rains having prevented the men from following-up the usual harvest work, and in consequence they have been employed in hedge-cutting, drawing straw for the thatchers, shaving the outside of wheat and oat ricks, &c. The second cutting of grass in the alluvial pastures and irrigated meadows will now be fit to cut for latter mow hay as soon as the ordinary harvest work is concluded. The men will also be employed in spreading manure on the clover leas intended for wheat. The cattle man must now attend to the heifers which have a young bull running with them and keep them frequently changed, and especially to provide a dry pasture for the night lodging; and as soon as it is known that all the heifers, including those which have turned have been served, the young bull should be taken up and tethered in a stall, or run loose in the house, and be daily subject to the attention of the cattle man in order that

he may have full control over the animal at all times. This is especially important, because it will be useful for a year or two longer when subservient to the manager. In some districts there is still much wheat and sheaved oats in the field, and the shocks should be kept set up every day. The shepherd now will attend the ewe flocks, and see that the rams are coloured on the chest with red, blue, or yellow ochre in order to observe which ram begets the best lambs, so that it may be retained in preference for the next year's service.

FAMOUS POULTRY YARDS.—No. 1.

COMBE ST. NICHOLAS VICARAGE (REV. HANS F. HAMILTON).

UNLESS we are much mistaken the fancy for poultry, and through it the useful improvement of the breeds of poultry throughout the country, has been as much advanced by quiet visits of fancier to fancier and comparison of notes as by all the poultry articles, all the poultry books, and all the poultry shows. A would-be keeper of high-class stock sees at some show birds which take his fancy, but he has a vague idea that they require some mysterious treatment (not entirely an erroneous one if they happen to have the ill fate to have been overshadowed), and that in ordinary quarters they may probably die, and so he ever puts off the day for starting with a pure-bred race. Or, again, he reads articles in some newspaper or chapters in some poultry book containing technical information for the experienced fancier; these too frighten him with their minutiae. A visit, however, to a well-arranged yard has a far different effect; there he may see sprightly birds not cooped in pens but running about with their natural grace, each has a history of its own; there he may learn that great beauty can be combined with the highest utility, and that some of the most successful prizetakers are reared in rough and primitive quarters. He may see bits of ground, heath, copse, orchard, or field which would hardly be either profitable or ornamental in themselves made attractive by pretty domiciles for the feathered stock, and troops of gay-coloured birds scattered over them. The ingenuity, too, with which dark outhouses and dull corners may be, and often are, converted into healthy habitations and sheltered runs for poultry is in itself interesting. We have vivid recollections of the enthusiasm which the first sight of a well-appointed lot of yards and aviaries aroused in ourselves, and many are the hints which we have learnt and adopted from establishments which we have visited. All our readers, however, cannot see great poultry yards, and the next best thing to seeing them is to read of them. We never saw the famed Inchmartine yards, but the accounts of them in "The Henwife" did much towards the development of our own. Through the kindness of many fanciers and friends—indeed so strong a bond of union is a rational taste, that there are many whom we once knew by name alone as enthusiastic fanciers whom we now number among our friends—we have seen a large portion of the most famous yards, and hope, however inadequately, to describe some of them for the benefit of others.

We do not begin with one of those establishments which have had their name and fame as far as our memory reaches back, but with one which is more interesting, because rising, and whose strains are in process of formation. For some three or four years have we observed in cup and prize pens magnificent Dark Dorkings and Dark Brahmas, each year of higher type, exhibited by the Rev. H. F. Hamilton. Their owner most hospitably invited us to pay him a visit to see the home of these birds and his lovely neighbourhood. It was late in July when we were able to avail ourselves of this invite—hardly the season for the inspection of the poultry, yet a capital one for the luxuriant vegetation around them, and never did we enjoy more the sight of a pretty place and well-filled yards.

Combe St. Nicholas Vicarage is an ideal place; though on the edge of Somersetshire the scenery leading up to it from Chard is more like that of Devonshire, with deep rich valleys and steep hillsides running up to gorse-clad and fern-clad downs. Steep indeed they are. It is well that Mr. Hamilton's horses are as good in their way as his poultry, for the sharp pitches of the road quite astounded us. Arrived at the Vicarage, we were at once struck with the beauty of its lawn. It rises from the front of the house in pretty slope and stretches out widely; in its centre are gay flower beds singularly well arranged for colour effect, on either side walks among trees and shrubberies; from the top of it runs far away a lovely grass alley, on one side of which is a well-filled border bank of flowers backed by a hedge, on the other a terrace-like walk, giving peeps over the nearer country to the far Devonshire hills. We have undertaken to write of famous poultry yards and not of beautiful gardens, so to the poultry yard we must go. On the left of the lawn parallel with the terrace and grass alley, but far below it, for all is on a hillside, runs a road towards the farm buildings and grass runs, which we shall presently come to; into this we descended, and the first thing which astonished our eyes was "the chicken house." It cannot be said of fancy poultry that they have fallen on evil days and evil times. The chicken house! Our infantile idea of a chicken house was a dark, windowless, fetid shed, with damp moss-grown brick floor, perches rising

up ladderwise towards the back, and the ventilation so arranged that the birds at roost were always in a thorough draught. Such is not exactly the construction of Mr. Hamilton's chicken house; what it is must be told in another issue.—C.

CRAVEN POULTRY SHOW.

THE twenty-fourth annual Show of the Craven Agricultural Society was held on the 30th ult. at Skipton. The entries were good in all sections, and the whole was a great success. The poultry were very wisely in the hands of paid attendants, which we consider a very wise provision, as all were well attended to. The birds were all of this year's hatch, and mostly shown in good bloom and entirely free from disease, such as was very common in the show pen a few years ago. *Game* headed the list, but contained nothing striking if we except the first-prize Black Red cockerel. *Cochins* were grand in both classes, the Partridge especially so, the first-prize pen containing such a pullet as we have not seen of late. *Brahmas* were very good in both classes, but in the Dark variety class one pen was left out, the cock being an old bird. *Spanish* were good; a capital pen could have been made out of the three winning pens. *Hamburgs* were very good as usual, the cup for the best pen going to Silver-spangles, the pullet in which pen was a marvel of her kind. *Game Bantams* were very good and in full feather, the whole of the prizes going to one yard; but the cream of the Bantam classes was the first-prize Black cockerel.

Pigeons were well represented in the Dragon and Antwerp classes, but the standard varieties fell short somewhat in entries.

POULTRY.—GAME.—*Black or Brown Red.*—Cockerels.—1, W. Rudd. 2 and 3, W. A. F. Fenwick. *vhc.* J. Wilkinson (2). *Pullet.*—1, T. Boothman, jun. 2 and *vhc.* W. A. F. Fenwick. 3, T. Mr. Hutton judged the poultry and Mr. Cannon the Pigeons.

COTTINGHAM SHOW OF PIGEONS, &c.

The annual Show of the Cottingham Society was held on Wednesday, the 28th ult., in beautiful grounds well adapted to the purpose, and the day proved fine and enjoyable. Poultry for the first time for many years found no place—Pigeons, Rabbits, and Cage birds only, but these mustered in much greater force than was ever the case there before, and the quality was also very high; but the otherwise excellent marquee, which in the wet would have proved a great boon, was too dark by far on account of the thickness of the canvas, and the light was wretched in the extreme.

Carriers were a grand display in both classes, the first-prize hen also securing one of the extras. *Turbits* were very good indeed, as also were the *Jacobins*; the first and second Reds almost equal in merit. *Fantails* and *Dragons* only moderate. *Tumblers.*—First and cup a capital Almond hen, closely pressed by one of the best cocks we have seen of late, *Antwerps* very good; the first a Short-faced Dun of capital head properties. In the Selling classes were some good Pouters, too good in fact to be sold at such prices as the list provided. In the Variety class first was a Fairy Swallow, second a Nun, and third a Suabian. *Pouters* came last, but these were a grand lot, Messrs. Fulton and Hairsine dividing the honours with some well-shown birds; a Black hen shown by the latter gentleman securing the cup for this section.

Rabbits produced some sensational doings, for in Lops one exhibitor, thinking to make himself more safe of the points prize, actually took another exhibitor's Rabbit out of his pen and placed it in his own, thus securing both first and second honours to count to his own credit. First was a Fawn doe, 2½ by 5½; second Black-and-white, 2½ by 4½; and third Fawn-and-white, 22 by 5; a very good class indeed. *Silver-Greys* a very good and large

class; first a good all-round Rabbit; second and third very close and better in ticking, but not quite as even. *Himalayan*, the winners three good ones, but rest poor. A capital Polish was penned here, whether by mistake or design we leave others to decide, but the exhibitor was present. The Selling class had a large and good entry, the first a good all-round Grey Dutch, second a Silver-Grey, and third Silver-Cream, many others being very highly commended. The Variety class was so good that it was divided and six prizes given. First and equal first Fawn Dutch and Silver-Cream; second and equal second Silver-Creams and Dutch; third and equal third to Dutch and Belgian Hare.

Cage Birds mustered well, the Grey Parrots proving an uncommonly good class, and the collection of foreign birds very numerous and good. In Canaries the Belgians headed the list, and these were such as we rarely see excelled. The winners were in good feather, and style of carriage was excellent—neat heads, long necks, and grand shoulders. The Norwich were an extraordinary class, Buffs winning the prizes, but the Marked birds were not good, and the British birds only moderate.

PIGEONS.—CARRIERS.—*Cock.*—1, R. Fulton. 2, H. Yardley. 3, J. Hairsine. *vhc.* R. White. *Hen.*—1 and 2, R. Fulton. 3 and *vhc.* H. Yardley. **TURBITS.**—*Blue or Silver.*—1, J. Hairsine. 2 and 3, Pickering & Hudson. *Any other colour.*—1, R. Fulton. 2, J. Hairsine. 3, Pickering & Hudson. **JACOBINS.**—1, R. Fulton. 2 and 3, J. Hairsine. **FANTAILS.**—1 and *vhc.* J. E. Loversidge. 2, H. Yardley. 3, J. Hairsine. **DRAGONS.**—1, E. Mawson. 2, H. Yardley. 3, R. White. *vhc.* W. Featherstone. **TUMBLERS.**—Cup and 1, H. Yardley. 2, R. Fulton. 3, J. Hairsine. Whole class very highly commended. **ANTWERPS.**—1, H. Yardley. 2, E. Mawson. 3, R. White. *vhc.* W. Stephenson. **BARDS.**—1 and 3, R. Fulton. 2 and *vhc.* H. Yardley. **OWLS.**—1, J. Hairsine. 2, R. White. 3, H. Yardley. **ANY VARIETY.**—Chickens.—1 and 3, J. Hairsine. 2, F. Stamford. **ANY OTHER VARIETY.**—1, J. Hairsine. 2, E. Mawson. 3, H. Yardley. **SELLING CLASSES.**—*Single.*—1, J. Hairsine. 2, G. Destner. 3, F. Stamford. *vhc.* D. Maynard. **Pairs.**—1, Hairsine. 2, F. Hudson. 3, P. Atkinson. **POUTERS.**—*White.*—1 and 2, R. Fulton. 3, G. Destner. *vhc.* J. Hairsine. 3, G. Destner. *Any other colour.*—1, R. Fulton. 2 and 3, J. Hairsine. *Any colour.*—*Hen.*—Cup, 1, and 2, J. Hairsine. 3, R. Fulton.

FOREIGN AND BRITISH BIRDS.—PARROTS.—*Grey African.*—1, Mrs. E. Gibson. 2, H. Smith. 3 and *vhc.* J. Gower. *Any other variety.*—1, L. Meinecke. 2, S. P. A. C. Constable. 3, Swain & Dobson. *vhc.* L. Meinecke (2), J. Gower. **PARROQUET OR LORE.**—1, A. Constable. 2, G. W. West. 3, L. Meinecke. **LOVE BIRDS.**—OR ANY OTHER VARIETY OF FOREIGN BIRDS.—1, J. Gower. 2, G. Purdon. 3, Swain & Dobson. *vhc.* W. Burniston. S. G. Hudson. **BEST COLLECTION OF FOREIGN BIRDS.**—1, Swain & Dobson. 2, L. Meinecke. 3, J. Gower. **CANARIES.**—*Belgian.*—1, J. Swain. 2, W. Forth. 3, —Hawksley. *vhc.* L. Meinecke. *Norwich.*—1, 2, and 3, W. Forth. *vhc.* C. Greenwood. W. Grantam. *Best marked.*—1, W. Hayward. 2, L. Meinecke. 3, C. Greenwood. **LARKS.**—1, Hall. 2, L. Meinecke. 3, J. R. Dulton. **ANY VARIETY OF ENGLISH FIELD BIRDS.**—1, Meinecke. 2, E. Nison. 3, J. Hogg. *vhc.* H. Harrison. R. Kneeshaw. C. Boynton. **MULES.**—1, W. Forth. 2, T. Lyon. 3, —Walker.

RABBITS.—*LOP-EARED.*—1 and 2, J. & E. Fell. 3, C. Clough. *vhc.* C. E. Thompson. W. T. Millet. **SILVER-GREY.**—1, T. & E. Fell. 2 and 3, J. H. Field. *vhc.* J. E. Winespear. C. Clough. S. G. Hudson. **HIMALAYAN.**—1, A. Hudson. 2 and *vhc.* A. Duck. 3, T. & E. Fell. **SELLING CLASS.**—1, E. Pepper. 2, —Hornet. 3, A. Canty. *vhc.* J. G. Abiart. S. Buckley, J. Graham. A. Canty. Doyle & Crump. J. E. Field. **ANY OTHER VARIETY.**—Equal 1, J. Foster. E. Pepper. Equal 2, A. Canty. C. Clough. Equal 3, J. Whitaker. T. and E. J. Fell. *vhc.* S. Buckley. A. Duck. M. Medley, M. Walker.

JUDGES.—*Foreign Birds.*—Messrs. Hutton and Coker; all others Mr. E. Hutton.

THE NATURAL AND THE ARTIFICIAL.

UNDER the above heading there is in your impression of June 20th a clever article by Mr. Pettigrew, with the object of eliciting the results of the use of artificial foundation. I read with great interest the articles emanating from the pen of Mr. Pettigrew, but I often say to myself what an American bee-keeper observed to an over-inquisitive visitor who by each query displayed his ignorance of the strides bee-keeping has taken of late years—viz., "Does this man take in the bee journals?" If Mr. Pettigrew does, then does he read them? Does he ever glance at the advertisements?

Writing for a journal occupying the proud position the *Journal of Horticulture* does Mr. Pettigrew ought to be up to the times, and read up, if he does not practise, be lore of the most advanced character. Had Mr. Pettigrew done so he would not base his calculations for cost of artificial foundation on the fact that one correspondent stated that he paid 1s. 6d. per sheet 18 by 22 inches, which is the price Messrs. Neighbour & Son charge for genuine American foundation, but he would have looked at the advertisements to see for the cheapest, and yet the best source, from which he as a bee-master with a number of hives to work could procure a quantity for, or manufacture it at for himself. In such a case Mr. Pettigrew would not have used these words: "Even if the bees adopt them readily and build upon them easily, the question that arises is this, Are they worth the sum?" I hold that page after page of the American bee journals for 1877 and '78, as also many pages in the "British Bee Journal," and the newest American work—to wit, "The A.B.C. of Bee-culture," by Mr. Root, 1878; "The Manual of the Apis," by Professor Cook of Michigan State College of Agriculture (published Chicago, June 1st, 1878), all bear ample proof that bees do accept foundation, and that it does pay.

But brother Jonathan does not buy in such a dear market as Mr. Pettigrew, oh, no. He reads the advertisements, and he finds he can get 5 to 10 lbs. 12 by 18 inches or any smaller size at just 2s. per pound, or if Jonathan and friends co-operate they can divide a thousand pounds between them at about 1s. 8d. per pound. I have weighed some sheets in my stock had from Messrs. Neighbour & Son 18 by 12 inches. Eight sheets weigh 2½ lbs.

Three and three-quarters of a sheet make up a pound, which gives the cost per pound as about 4s. It is not this cost but the American prices that in the future of artificial foundation will be the basis for its cost, plus or minus the difference of value of wax in the United States and England. At present fancy prices rule, and if Mr. Pettigrew were wide awake to his own interest he would be in possession of a machine to-day and turning out a large quantity per day as long as novelty lasts. He could have been coming, but he has left it to others who by their foresight advance the cause of scientific bee-culture, and earn the honest penny also.

Here in Algeria I have tested the value of foundation, and I believe the day is come when the scientific bee-keeper who works for profit will not be without it. My observation and practice lead me to discard the natural comb, and when a fresh comb is necessary I employ foundation. I quite agree with the best American authorities in that for the brood chamber "foundation is a magnificent success," but that for supers, unless an excessively thin foundation be used, it is best not to tack on the word "artificial" to super honey, and so leave it open to the charge of being adulterated. Let me mention a few points wherein I think it pays to use foundations, assuming that all persons know that the best gives not only the base of the cells but shallow side walls with enough wax to form the sides of the cells.

By introducing a swarm to a hive supplied with foundation I insure combs perfectly straight, and positively priceless when you come to use the extractor. I insure all worker comb, a little drone comb, or none at all, just as I chose. I have given the bees wax enough, and no more, to make their combs without their having consumed honey to secrete it. In twenty-four hours several sheets of the foundation will be worked out three-quarters of the full depth of the cells, and each unfinished cell may actually contain an egg. Each sheet of foundation, now a frame of honey-comb, I can with growing interest hold in my hand, while my bees quietly proceed with their work—yea, even find the queen mother, follow her as she proceeds to inspect each cell, which, finding suitable, she soon tenants with an egg, apparently unconscious that the writer has her well in the focus of a powerful lens, and can observe a natural phenomenon that Huber and other great and observing men never saw with such facility. Again, this August 21st have I observed the queen laying with naked eye, and on bright new foundation comb each movement is easily visible. Of the population of a swarm to which foundation is thus given two-thirds will be out honey-gathering, while the remaining third elongate the cells and tend the young, &c. Had the swarm no foundation two-thirds of the population must stay at home to aid the wax secretion by mutual warmth, &c. Here is a direct gain through being able to send more labourers to the fields at the most precious period of the year. The swarm has had eight sheets at 1s. 6d., value 12s., given it. These weigh 2½ lbs., which weight of wax represents an actual amount of Mr. Pettigrew's honey at 1s. 3d. per pound.

Opinions vary as to the precise weight of honey consumed by bees to secrete 1 lb. of wax. We will err on the safe side, and take that 5 lbs. of honey go to make 1 lb. of wax. Then the swarm was started with a gift of an equivalent to 11 lbs. honey at 1s. 3d. per lb., value 13s. 9d., but the foundation cost 12s., and the balance therefore is on the side of foundation. At once, with this calculation fresh in our minds, let us take the possibility that it only takes 3 lbs. of honey to produce 1 lb. of wax, this being the conclusion arrived at by Mr. Vignoles in France after experimenting, and contrast that with the American prices:

Wax foundation 2½ lbs. at 2s. per pound 4s. 5d.
 6½ lbs. of Mr. Pettigrew's honey at 1s. 3d. per pound ... 8 2
 Is there not a balance of 3s. 9d. on the side of artificial foundation? Add these apparent facts to the advantages I have mentioned, and I leave it to your readers to judge whether or no foundation will pay.

Later on I hope to see my convictions endorsed by such able writers as your esteemed correspondent "B. & W." and others, not forgetting Mr. Pettigrew, who can easily experiment next spring.

At the moment of writing this letter I have received the American "Bee Journal" for August, and from it I cut a portion of a letter bearing on the subject in hand. The letter is dated July 14th, 1878, and reads:—"Arkansas, Wisconsin.—Two apiaries close by us of twenty-three colonies each have not had a single swarm yet. I intend to use the Langstroth hive altogether next year. I found the comb foundation a present help in time of need. I used 25 lbs. with good success. This is my experience with the foundation. I have doubled my stock by its use, while my neighbours in the bee business have just as many colonies as they had when the working season commenced and no more, and in no better shape than ours are now."

I need only say that these observations tally with my experience. The desire to answer Mr. Pettigrew's remarks suggested to me the advisability of making an experiment by transferring an Arab hive recently purchased, carefully noting its progress, and giving your readers the benefit of the same. As my hives contain thirteen frames 13½ by 8 inches, and there was only brood enough to barely fill three frames, I had to fill up the hive with ten frames

of foundation. I estimated the bees to weigh about 5 lbs. The hive card reads as follows:

HIVE No. 42.—An Arab hive transferred August 9th, 1878. Three frames brood, ten frames foundation, bees of native breed—Apis fasciata.

August 10th.—All sheets of foundation worked out more or less. One sheet having fallen down, although partly worked, had to be replaced by a fresh sheet.

August 11th.—Every sheet of foundation worked out, and those next the brood extended entirely, and fresh-laid eggs in some of the sheets.

August 13th.—Fresh eggs fill three sheets foundation entirely. Honey in three also. Four sheets of foundation are not quite extended, but have honey stored in them.

August 19th.—Caught queen and clipped her wing. Plenty of fresh eggs and brood. Extracted honey in six frames.

August 21st.—Honey stored in frames that were extracted.

August 26th.—Saw queen. I was obliged to extract one frame of honey to give queen vacant cells to lay in.

August 27th.—All going on well.

I will conclude my observations by saying that for warm climates foundation obviates the necessity of storing empty frames of comb, which so soon become a breeding ground for moth. I am, therefore, determined to get a machine and make my own foundation for the future.—ARTHUR TODD, *Algeria*.

OUR LETTER BOX.

KERRY COWS (*Capt. Thompson*).—If you communicate with Mr. Wicken-den, Maynard's Green, Horeham Road, Hawkhurst, you will no doubt get some information about Kerry cows. He has a very fine herd of these useful little animals.

GAME BANTAMS (*Amateur*).—We never like to recommend anyone. You had better consult our advertising columns.

BEES FIGHTING (*W. E. G.*).—In feeding bees in autumn great care should be taken to prevent fighting. All feeding should be done after sunset in favourable weather, and nothing left about the hives fed to attract strange bees. If feeding be done in a careless way at this season all the bees in the neighbourhood become excited with robbing propensities. The bees that you see rolling off the right boards of your hives are strange bees or robbers stung to death. Suspend feeding for a few days and contract the doors of your hives. All will be well.

REMARKS.

28th.—Fine bright morning, heavy showers afterwards.

29th.—Dull and showery, but the sun shone occasionally; thunder at 9.15 A.M., a very rough night.

30th.—Alternately dull, showery and bright; a very heavy shower at 0.45 P.M. one vivid flash of lightning at 0.47 P.M.

31st.—Showery with a little sunshine.

1st.—Rather dull all day but no rain.

2nd.—Morning rather dull; brighter in the afternoon.

3rd.—Fine bright day.

The first part of the week was very unsettled, Friday and Saturday being particularly wet. The barometer, which had been rather low for some time, fell rapidly just before 8.30 A.M. on the 30th, but from that time it rose steadily and the weather improved, the last three days being fine with a high barometer. Barometer higher than last week, temperature rather lower, rainfall heavy.—G. J. SYMONS.

COVENT GARDEN MARKET.—SEPTEMBER 4.

TRADE still keeps quiet, there being no recovery from last week's quotations. Peas are the main supply, reaching us from the Continent, and consist of Williams' Bon Chrétien and Duchesse d'Angoulême. Kent Cobs and Filberts, owing to shorter supply, are selling freely at higher rates.

From observations taken near London during forty-three years, the average day temperature of the week is 67.8°; and its night temperature 46.1°.

BULBOUS PLANTS FOR WINTER AND SPRING DECORATION.

VARIOUS nurserymen's catalogues and advertisements of the Hyacinth and other Dutch flower roots remind us that notes on the culture of bulbs, and also which varieties to select, may be useful to those who have hitherto had but little success in the management of these fragrant and beautiful flowers, which with care may be had in beauty from December until the first week in April.

To have Hyacinths in flower at the earliest time here mentioned bulbs of the Roman Hyacinth must be purchased at once and potted on arrival, placing five or six bulbs in a 6-inch pot, using a compost of light loam, plenty of sand, and leaf soil. After potting plunge the pots up to the rims, covering the tops over with a thick coating of cocoa-nut fibre, which may be purchased very cheaply and does not injure the bulbs like coal ashes. Roman Hyacinths cannot be compared with the Dutch Hyacinth for magnificence of spike and beauty, being more like our wild wood variety; but for earliness of flowering, combined with the purity of its flowers, it is fast becoming a popular favourite for the making of bouquets, wreaths, and other decorative purposes. When the potting and plunging are completed the bulbs may be left undisturbed until the beginning or middle of October, or later, according to the time required for flowering. The most advanced at that time should be collected and removed to a frame or pit and brought on very gradually, much in the same way as is directed for the larger-flowering varieties; but at no time subject them to a strong temperature, or they will become drawn and lanky. Give water copiously when the plants are throwing up their miniature spikes and while in flower. For mixing in conservatory borders or for front lines potfuls of Roman Hyacinths will be found invaluable and last a long time in flower.

Having now for several years grown some very good examples of what are termed Dutch Hyacinths for exhibition, and that with a fair amount of success, I can strongly recommend the following thirty-six varieties as constant and to be relied upon for uniform and handsome spikes:—*Reds*: Charles Dickens, Emmeline, Fabiola, Gigantea, Ornement de la Nature, Macaulay, Prince Albert Victor, Princess Clothilde, and Von Schiller. *Whites*: La Grandesse, Grandeur à Merveille, Madame Van der Hoop, Baroness Van Tuyll, Alba Maxima, Paix de l'Europe, Alba Superbissima, and Mont Blanc. *Blues*: Grand Lilas, Blondin, Lord Derby, Charles Dickens, King of the Blues, Baron Van Tuyll, Marie, and General Havelock. *Lilac or Mauve*: De Candolle, Haydn, and Sir Henry Havelock. *Yellow*: Bird of Paradise and Ida. The thirty varieties named are all single, and the following half-dozen are amongst the best of the double varieties and complete the number mentioned above:—Koh-i-Noor, Lord Wellington, Blocksberg, Garrick, Laurens Koster, and Van Speyk.

The best twelve varieties are undoubtedly Koh-i-Noor, Von Schiller, Macaulay of the reds; La Grandesse, Grandeur

à Merveille, Alba Maxima, and Baroness Van Tuyll of the whites; King of the Blues, Grand Lilas, Charles Dickens, and Baron Van Tuyll of the blues; with the yellow Bird of Paradise. Other varieties may produce equally large spikes and fine bells, but those named are always constant, and will be found in every prize collection. To still further select: Von Schiller and Macaulay are the very best of the reds; La Grandesse and Grandeur à Merveille take the same place amongst the whites; while King of the Blues and Grand Lilas are in the foremost rank amongst the blue varieties.

Having giving the selection I will state the best way to proceed with their successful culture, observing first that those who contemplate growing for exhibition should order three or more bulbs of the same varieties; for it may so happen that if only one bulb is ordered it may not be fully matured and produce a spike somewhat too small, or it may throw up two or more trusses instead of one very large one. The vendors of these bulbs no doubt try their very best to select solid and well-matured bulbs, but Nature will at times deceive the most experienced. All varieties do not become matured at the same age, and therefore those who wish to gain first honours should grow several bulbs of a few constant varieties rather than one each of a greater number of sorts, and then form a selection from the very best spikes produced. A well-grown Hyacinth should have the foliage tolerably short, broad, and stout, so that it stands bold and erect; the stem of the flower spike should not be longer than the leaves, and the spike should be fully developed above the leaves. As soon as the bulbs arrive it may be well to examine them, and those intended for exhibition should be put carefully away until the middle or end of October, when they may be potted; but those intended for forcing should be potted at once, using a good mixture of sandy loam, leaf soil, and thoroughly decayed dry cow manure.

Have in readiness a sufficient quantity of 48 and 32-sized pots, using a fair amount of good drainage, fill the pots with the compost; make a hole with the fingers sufficiently large to receive the bulb, which should be placed in sharp silver sand, the top of the bulb to be on the level with the top of the pot. When potted press the soil firmly all round. By adopting this method the bulbs while making their roots are not so likely to be lifted out of the soil as when they are pressed down into the compost. Place the pots out of doors on a hard bottom, and cover sufficiently with cocoa-nut fibre refuse to keep out sharp frost. In this position they should remain until the first week in the new year, when the fibre can be easily cleaned from them, and the bulbs gradually inured to the light. For the first few days after removal either small pots should be inverted over the bleached crowns or they should be shaded with a mat until they become green. The flower spikes are plainly visible while in this undeveloped state, so that a look-out must be made for slugs, mice, &c., or they may cripple an otherwise good spike of bloom.

A low span-roof pit or a shelf near the glass in a greenhouse are good places to bring them along gradually to bloom during March. No forcing will be required from

this time onwards. Weak liquid manure may be given them with beneficial results, and nothing appears to suit them better than very stale manure water that has been exposed all the winter, to which may be added a small quantity of soot. Never allow them to become dry after this; and as the spike grows it will require supporting. The best and neatest mode of doing this is to bend some wire about 3 inches at one end, then bend it again about $1\frac{1}{2}$ inch, thus— having a straight upright piece about 18 inches long, which must be carefully placed inside the bells, the spike being neatly tied to the wire. The wire may be made secure at the bottom by driving a notched stick tightly by the side of it, and securing both together with strong matting; in this way the trusses will travel for miles without the least injury, and the supports are scarcely visible. Should the wire be too long for the truss it can be easily shortened with a pair of wire-cutters at the last minute.

It is always an advantage and adds greatly to the symmetry and beauty of the spikes to dress them. With a couple of small smooth sticks or ivory points of the size of a cedar pencil the uppermost pips are lifted up, and so on until the whole mass are raised. The curl of the pips is generally sufficient to support each other.

At the London shows double spikes are excluded in some classes; but it is folly to try and exclude fasciated spikes, for all the best trusses are more or less fasciated and some particularly so. Most exhibitors plunge the 6-inch pots in which Hyacinths are grown inside larger pots, the surface of both being covered over with fresh green moss, which adds greatly to the good appearance of the plants on the exhibition table.

Tulips require much the same soil and treatment as Hyacinths, only that some decayed horse droppings may be advantageously incorporated with the soil in the place of the cow manure. Place three or four bulbs in 6-inch pots, and when the flowers commence opening a slack ligature should be tied round each bloom to prevent it fully opening. Five or six varieties are all that are required to be grown for exhibition; and White Pottbakker will be found the most useful white; Vermillion Brilliant the best scarlet; Keyzers-kroon, a large showy scarlet and yellow; Prosperpine, rosy crimson, the finest Tulip grown of its colour; Van der Neer, rich violet; and Fabiola, white striped with red.—J. W. MOORMAN.

NECTARINES.

By many the Nectarine is considered the richest and most agreeable fruit in cultivation; still, the Nectarine is by no means plentiful or even common, for in large gardens usually it is not so numerously grown as the Peach, and in many small gardens where a few Peach trees are cultivated the Nectarine is not to be found. This is a mistake, and I am sure everyone would prove it to be so did they grow a few Nectarine trees. In all points of culture they are no more difficult to manage than Peaches, and I consider both of these fruits as easily cultivated as Plums, Apricots, or any other stone fruits.

Although Nectarines do tolerably well with us out of doors, our position being sheltered, they might not succeed so well everywhere; but there is no danger of failure with them under glass, and they do admirably in unbeated houses. I am sure it would pay anyone handsomely to put up a light glass structure without any heating appliances and plant it wholly with Nectarines, and in favourable localities and in sheltered positions a number of trees might always be planted out of doors against south walls. According to our experience they are a more profitable and certain crop in such positions than Apricots.

In starting Nectarines either under glass or in the open air a beginning should be made with two important things—viz., new soil or properly prepared borders, and healthy young trees. Nectarines will always thrive admirably in soil which produces good Grapes, but there is less manure required. Good drainage is very essential to the well-being of the Nectarine, and to this too much attention cannot be paid. Two feet is quite deep enough for the border, and where the ground is naturally damp it may be raised half this depth above the level. When planted against open walls the border may be made from 8 to 12 feet in width. When planted in lean-to houses with trees in front and others against the back wall the whole interior of the house should be border. In addition to the bottom drainage it is a good plan to place a little mound of broken bricks as a station for each tree. As to loam, that

of a moderately heavy yellow description suits well, and with this we generally mix a good quantity of old lime rubbish, charcoal, and burnt refuse of any kind, adding more or less as the soil is open or retentive. At first no manure should be mixed with the soil, but a few bones broken small act beneficially. In after years a slight top-dressing of half-decayed cow manure may be forked into the surface of the border as it is seen it is necessary.

From the first great care should be exercised in pruning and training. The pruning is never a heavy undertaking, as in summer the shoots should be laid in and tied to the trellis or wall, cutting out weak growths and shortening back any that are straggling from the others. When this is attended to in proper time little or no pruning is necessary in winter, and when any is wanted it is simply doing the same thing as was done, or should have been done, in summer. The foliage must also be kept clean at all times. A good border, healthy root-action, and abundance of water during the growing season will do more than anything else to ward-off all kinds of insects.

Nectarines will bear forcing quietly like Peaches, and by this means they may be had ripe in May or early in June. Lord Napier, Elruge, and Hardwicke are the best for coming in early; Violette Hâtive and Pitmaston Orange next, and Newington late. These are the principal if not all the best Nectarines in cultivation.—A KITCHEN GARDENER.

AUTUMN ROSES—A DAY AT CHESHUNT.

A DAY spent at one of the principal courts of the queen of flowers must always be a red-letter day in my life, and a few days since I was privileged to spend a long day with that ardent and excellent rosarian Mr. George Paul. I went there for the express purpose of finding out what Roses bloom most freely in autumn, and a better place I could not have chosen. The day was dull and showery and the Roses had suffered much from the unseasonable weather we have had of late, yet many of them were blooming so very freely that I was enabled to form a good judgment as to the autumnal varieties. To my great delight I found Mr. Paul at home, and was most heartily welcomed by him. After examining the home nursery and refreshing me when weary he kindly drove me to his High-beach nursery. This is distant six miles from Cheshunt, and is on the fringe of Epping Forest. I shall hope hereafter to give you a description of this lovely place, for the description of the home nursery will occupy enough of your space for one week; but I cannot quit the subject without remarking that I never saw a more lovely place, and that I could hardly believe I was within fifteen miles of Charing-Cross, so rural and retired was the situation.

Mr. Paul's Roses are worked on all sorts of stocks—on the Briar, the Manetti, the seedling Briar, and a new stock I know nothing of called the De la Grefferie. It is, I believe, an old China Rose.

To give your readers some idea of the numbers cultivated at Cheshunt, on one piece there are five acres of standard Roses, four acres of Manetti, and three of seedling Briars. The plants were splendid in growth. On one Manetti I counted twelve shoots, and on a standard Rose ten. In another field there were four acres of Manetti and three acres of standards for next year. The budding for this year was nearly finished, and boys were busily engaged removing the cotton strapping. This was a novel practice to me. I had been accustomed to see the cotton left on till the following spring. Mr. Paul, however, wants it removed as soon as possible so that the bud may become ripe, and certainly the practice seemed to answer.

Another most excellent plan adopted here is to bud the same sorts on Manetti and Briar opposite to one another, so that a visitor going down the walks would see the same Rose on each stock, and could observe its growth and judge for himself which stock suited the particular variety best. We went carefully through the seedlings and new Roses. I was very gratified at finding most of Mr. Paul's own Roses were good autumnals. I saw one or two unnamed seedlings which promise very well. One very like Madame Charles Crapelet struck me very favourably, and another from Charles Lefebvre was very good. It is at present so like that variety that Mr. Paul hesitates to send it out; he will therefore keep it at home another year. Of named seedlings as yet not sent out, one named after one of the Editors of this Journal pleased me much. Dr. Hogg is perhaps the bluest Rose in cultivation. Partaking somewhat of Pierre Notting in colour and Louis Van Houtte in form, I

shall be much surprised if the Doctor does not turn out to be an acquisition. But—truth must be spoken—the Doctor is nowhere beside the Duke of Teck. This variety is the brightest scarlet Rose yet raised. It is most vivid, and by far the best seedling from the Duke of Edinburgh I have yet seen. It is of good form and double, and of dazzling brightness, and an immense advance upon all others of this class of colour. Another Rose which cannot be too highly praised is Charles Darwin. This is one of the freest autumnal bloomers to be found anywhere. It is very dark in colour, and in form like Fisher Holmes. All the Roses I have yet named are good autumnal bloomers. To these must be added Duke of Connaught, which as seen at Cheshunt is *nulli secundus*, and Lady Darnley.

John Bright, one of Mr. George Paul's, and Magna Charta, one of Mr. William Paul's, will not bloom in the autumn at Cheshunt, and I shall see whether they will do so at Waltham Cross.

One of the new French Roses of last year is a good autumnal bloomer and a valuable light-coloured Rose; it is called Comtesse Adèle de Murinais, and is very like Mrs. Rivers in colour and form. Sultan of Zanzibar, the grandest of all Mr. Paul's children, is also a good bloomer at this season, and Cheshunt Hybrid keeps him company. With regard to this last-named Rose, I may say that Mr. Paul no longer calls it a Tea, but classes it and two new French Roses of this year as Hybrid Teas, and as such they will appear in his new catalogue. It remains, therefore, for secretaries to decide whether they will allow Hybrid Teas to appear in a box of Teas and Noisettes.

Of new or comparatively new Roses noted for their true perpetual character I noticed Sophie Fropot, somewhat like Laelia in form and colour, and Madame Gabrielle Tournier. Mr. Turner's Oxonian and Mr. Laxton's Empress of India are also both good bloomers now; so are Emily Laxton and Duke of Connaught. This Rose may be described as truly splendid both in form, which partakes of the Charles Lefebvre character, and in colour, which is scarlet veined with purple, and it is also one of the freest bloomers in autumn. Abel Carrière and Duchesse de Vallombrosa are also good Perpetuals, and Capitaine Christy one of the best, also that grand Rose Jean Liabaud. Of older varieties most conspicuous are the Bourbons. Modèle de Perfection, Bourbon Queen, and, in fact, all the Bourbons, are splendid at this time of the year.

Of the Hybrid Perpetuals of the darker varieties I should unquestionably say that Annie Wood is the best, and of the lighter ones La France. Henri Ledechaux, a grand autumnal on the Dog Rose, will not do on the Manetti. Duke of Edinburgh, Madame Victor Verdier, and Charles Lefebvre are also fine Roses in August and September. Of the true rose-coloured varieties Edouard Morren and Paul Neyron are the best; good also are Abel Grand and Auguste Rigotard. Dr. Andry, that grand old Rose, is also a fine and free bloomer now. Marie Baumann and Alfred Colomb possess this as well as all other virtues. The very dark varieties, Abel Carrière, La Rosière, Camille de Rohan, Louis Van Houtte, and Pierre Notting, are all Perpetual. Marquise de Castellane, Marie Finger, Dupuy Jamain, and Royal Standard, all these are good. Among the lighter shades Comtesse de Serenye, Princess Mary of Cambridge, Bessie Johnson, Mrs. Bellenden Kerr, which is the finest Rose of the Middle Bonnaire stamp, are all good bloomers at this season, as are also Boule de Neige, Baronne de Rothschild, and Princess Beatrice.

All the Teas with the exception of Souvenir d'Elise are good free bloomers, but the most noticeable are Belle Lyonnaise, Madame Berard, Rubens, Madame Falcot, Safrano, Marie Van Houtte, and Souvenir d'un Ami.

Of the Noisettes Céline Forestier, Triomphe de Rennes, Rêve d'Or, and Solfaterre are the best, but all the Noisettes do well except Cloth of Gold.

I could mention many more, such as Jean Cherpin, Prince Arthur (Mr. Cant's seedling), and Sénateur Vaisse, but I am afraid to occupy more space with a list of names. I have given a list sufficiently large for any amateur grower to choose from. I can assure him that if he will order any of those above named he will have true Perpetuals, and will enjoy a feast of Roses in autumn. Many people have no chance of seeing Roses till late in the year. The rich and great are in London when the summer Roses bloom, and except at Rose shows they never see a Rose; but in August and September they are far from the madding crowd and can enjoy their flowers. They come at a time when all can enjoy them, when as a rule they are less likely to be spoilt by the weather, and

their blooms, if not so numerous as in summer, linger with us longer and are more fragrant.—WYLD SAVAGE.

PUNCTURING FIGS.

THE following extract from Loudon's "Encyclopædia of Gardening" may be of use to "H. F. C.:"—"A very general French practice is to prick the fruit with a straw or quill dipped in olive oil. In Italy a wound with a knife is sometimes made on the broad end of the Fig, or a very small part of the skin of the fruit is removed for the same purpose. . . . Monck split a Fig from the eye to the stalk, and found it ripened six weeks before others which were left untouched."

All the good the puncture can possibly do is to admit air to the interior of the Fig and thereby hasten the impregnation of the flowers, which under natural circumstances does not take place till the Fig is half grown or more. The oil or spirit used may possibly help to heal the wound made. In such a treacherous climate as ours the puncturing would possibly do more harm than good, as the Fig blossom is very tender and might be expected to suffer if exposed to our low night temperatures before its natural time. Nevertheless, if there is the remotest chance for a longer succession of fruit by puncturing a portion, or by any other means, it is worth the serious and unprejudiced attention of cultivators, for when we have a crop of Figs there is generally rather more than enough of it for a week or two, and then it is all over.

In the number of this Journal for January 31st this year is a woodcut of the Fig blossom, with some descriptive matter explaining the natural method of fertilisation, and also an extract from a Naples' correspondent relative to the puncturing of the fruit. As stated above, Monck's split Fig ripened six weeks before the natural time. The natural time for ripening in this country is the end of August or beginning of September. We will say then that Monck's Fig ripened in the middle of July, and it must have been operated on some considerable time before then; we will suppose it was split in the middle of June, and if I were going to experiment on the subject I should begin at that time and carry on a series of experiments with a few fruits at a time till the end of July, fastening the date of puncture near each fruit with a label.

It must not be expected, however, that puncturing of Figs will prevent imperfect fruit falling, whatever it may do towards hastening to maturity that which is perfect. As will be gathered from the above, the fruit grows to a considerable size before flowering, and there is also a great difference in this respect with different varieties; the White Marseilles, for instance, appears nearly full grown in size before the end opens to admit air for fertilisation, and on account of its comparative late flowering it is one of the best Figs to grow in this country. When Figs fall before coming to their full size it is generally a sign that the wood has not been properly matured during the previous season. In a summer like that of last year the growth of Fig trees was not matured in any but the most favoured localities, and consequently the crop in less favoured places is a failure.

Figs grown on chalk or near the sea will generally take care of themselves, but otherwise they often require special culture, and one of the principal points is to prevent them making gross growth which they cannot mature. This is best done by confining the roots and spreading the branches thinly over a large space, at the same time avoiding cutting as much as possible.—WILLIAM TAYLOR.

VALLOTA PURPUREA AT SUMMERHILL.

THIS is one of the handsomest and most brilliant of the whole Amaryllis family, and were it more generally known that its growth is so easy and profusion of bloom so magnificent and continuous, its culture would necessarily become more extensive. It need not be stewed in a stove or parboiled in an Orchid house; it need not—should not—be potted or repotted every season; it need not, or ought not, be indebted to any other Lily, Maidenhair Fern, &c., for foliage to ornament its flower scapes when used as a cut flower. So much for some of the negative "necessities" (?) commonly believed respecting this valuable Amaryllis. The flowers are bright crimson scarlet, except in case of sports, which I believe seldom occur; and, whether used as cut flowers or for conservatory decoration, find few compeers. In this locality one of the finest collections is that possessed by Mrs. Moore, Summerhill,

and admirably grown by her assiduous head gardener Mr. Thomas Hanrahan. I have visited her conservatory, which is always a model of neatness, in midwinter and a few days since in midsummer, and on each occasion the most striking and conspicuous objects were undoubtedly well-grown bright crimson Vallotas. Other objects of interest were not absent, of which I can quote a few from memory:—*Achimenes*, *Gesneras*, *Gloxinias*, *Crotons*, *Coleuses*, *Dracaenas*, *Stephanotis*, *Hoyas*, *Ficus elastica*, *Caladiums*, *Tacsonias* intertwining with a beautiful *Cobaea*, with a well-grown collection containing many rare varieties of *Begonias*, *Fuchsias*, *Pelargoniums*, &c.

Among several specimens of Vallotas now opening into bloom I noted one, and found it was throwing up twelve flower scapes, and had on each an average of eight blooms. These were grown in an 11-inch pot, and had not been disturbed for several years. This is merely a specimen of several others, many of which had gone out of bloom, and which I understand were much better.

The effect of such a display tastefully arranged in a conservatory is unique when the flowers are fully expanded. Mr. Hanrahan has them in flower almost continuously from January 1st to December 31st, and their adaptability is remarkable. The coming display is exposed on the vinery stage to the full influence of the sun. Those to come on by-and-by are under it, and those still later required will do admirably by a south wall. In fact, were it not that they start into bloom during midwinter no extra heat would be necessary for almost any *Amaryllis*, and this, if I remember right, is the opinion of Mr. Taylor, a much better authority.

I may now conclude with a few words as to the story of its culture. If the bulb you start with is 2 inches or less in diameter, a 6 or 7-inch pot will be amply large for two or three years. The soil should be rich, and as the roots are never shaken out or extricated from it, it must be lasting. Good fibrous old loam and peat, with a fractional part of dry and rent-asunder cow manure thoroughly aerated; but for continuous use and nutriment broken bones are most necessary, as well as some nodules of charcoal. Those who may be curious enough to turn out a pot on their hands after the roots are developed will see them interlaced round and round the bones and charcoal, and when healthy the points are beautifully tinted red. Need I say those observations apply almost equally to the whole *Amaryllis* family?—W. J. M., *Clonmel*.

JUDGING MELONS.

SOME years ago, when I was in the habit of frequenting the horticultural shows at Edinburgh, Glasgow, and the north generally, there was a rule that bunches of Grapes shown for the finest flavour should be above a certain weight, $1\frac{1}{2}$ lb I think it was; and this excellent plan always secured a competition with ordinary-sized bunches instead of allowing only a few berries to be shown as a bunch. At several horticultural shows I have visited this season I have thought that those who arrange show schedules or prize lists would do well to have a similar rule with regard to Melons. It has been simply absurd giving prizes to some of the Melons which I have seen honoured this season. I have not a word to say against paying due regard to flavour, but I think size in Melons should always carry weight and be regarded as an indispensable accompaniment.

As a rule there is always large competition for Melons. In several instances this year I have seen as many as thirty fruits shown together, and nearly always with the same result—the smallest fruit first; in some cases shabby little fruit not over half a pound in weight, such as I fancy few gardeners would care to place on the table. Had I the framing of a prize list it would be stated that no Melon under 2 lbs. would take a prize. This would bring forward handsome fruits without going to extremes, and that exquisitely flavoured fruit can be had of this size is a fact well known to every Melon grower. Small Melons are no finer flavoured than large ordinary-sized fruits as a rule, only small ones ripen quicker, and no doubt it is this which gives them sometimes a little superiority in flavour; but in the end they have no more merit than larger fruit, and in all other points they are very far behind.—A KITCHEN GARDENER.

ROSES IN POOR SOIL.

EVERYONE must have read with sympathy the lament by "WYLD SAVAGE" over the soil in which he is condemned to grow his Roses. I would willingly offer a suggestion, for what

it may be worth, to ameliorate perhaps his position, but before doing so a little more specific information is necessary. What is the nature of the soil? He speaks of its cracking with drought, which suggests clay; but he also speaks of its being light and flinty. Is it clay, gravel, or chalk, retentive of moisture or dry, and of what depth, and what is the subsoil? About a year ago he asked for a substitute for farmyard manure. I suggested certain artificial compounds: has he tried them? and if so, in what quantities, at what times, and with what results? I think he has spoken of using guano; that is an excellent manure, but not a substitute for dung, because its excess of nitrogen and deficiency of potash renders it too stimulating to be used in sufficient quantities alone.—K.

OUR BORDER FLOWERS—POPPYWORTS.

THE perennial species of Poppies are not a numerous race, yet many of them are attractive. They are a family among our border flowers that are far in the background as regards cultivation, and why plants so attractive and with such gorgeous colours are not more to the front is to me a little puzzling. The taller-growing kinds, such as *Papaver orientale*, syn. *concolor*, with its monstrous scarlet flowers; *P. maculatum superbum*, and *P. bracteatum*, syn. *pulcherrimum*, are all well adapted for open spaces in large borders and in the shrubbery. When cared for they are grand objects seen at a distance.

Fig. 31.
Papaver nudicaule.

They are not at all particular as to soil, yet the places intended for their reception are all the better for being thoroughly broken up to the depth of 2 feet, the soil being mixed with good sandy loam, well-decayed vegetable matter, and coarse grit or sand, and they must have efficient drainage. When established and cared for they last many years. When the stools become large they are the better for having some of the young growth thinned out, for when left too thick the stems are liable to decay. They are increased by division in the autumn or spring when commencing growth.

There are many other beautiful kinds, none more so than those gems of alpine beauties *Papaver alpinum*, *P. alpinum album*, *P. alpinum miniatum*, and *P. pilosum*, syn. *olympicum*. Amongst these must be classed *P. nudicaule* (fig. 31), which being found only on one spot in the British Isles, must be considered as among the many plants of which it may be questioned whether they are really natives. Its flowers are as sweet-smelling as the Jonquil, emitting their fragrance especially during the cool of the morning and evening. Sir W. Hooker and Dr. Lindley have enrolled it in their catalogues of our native plants. Linnæus doubted whether it is not a variety of *Papaver alpinum*, or Alpine Prickly-headed Poppy. Being a native in great abundance of the shores and islands of the colder regions of North America, a seed may have floated to the coast of Ireland. When well grown the contrast of colours in these species is charming—yellow, white, and red.

To have the plants in perfection they must be well cultivated, and then they repay any amount of labour bestowed on them. They prefer the rocky, providing them with thorough drainage, and water when required. They are all the better for partial shade. Good sandy loam, leaf soil, peat, and charcoal dust mixed together will meet their requirements.

They may be increased by seed sown in the spring on a moist sheltered border, or by division after flowering in the spring. Care must be used in the operation of division.

All things favourable, they are equally adapted to border culture.—VERITAS.

THE AMERICAN BLACKBERRY AN ORNAMENTAL CLIMBER.

OVER a path in the garden of Mr. E. J. Sinden at Uckfield there is an arched trellis of simple curved iron rods partly covered with the growth of several flourishing young plants of a large American Blackberry. This bower is just now an attractive sight. The elegant pinnatifid foliage, always orna-

mental, gains in beauty from the large pendant clusters of glossy black fruit now hanging in great abundance over and nestling so charmingly among it. It is an arcade of great and growing beauty, always affording pleasant shade at a season of the year when shade is desirable, and now yields a valuable supply of fruit for making blackberry jelly, which is even more important from a practical point of view.

Nothing can be better than this method of training a really valuable fruit. It is a material aid to that economy of space so important in all gardens, and especially so in a small one. The fruit, moreover, is more easily picked than when the growth is permitted to ramble in a wild thicket, and the fruit is kept from contact with the soil; and yet I must confess to a wish to see wild thickets of it among bold rockwork, and also to afford it the prominent place among ornamental climbers on buildings of which it is worthy.—EDWARD LUCKHURST.

LOSS OF THE FRUIT CROP.

REGARDING the products of the earth, second only in importance to farm produce is the fruit crop, and so important is the latter that many farmers are already turning their attention to it by commencing fruit-growing. There is no effect without a cause; and especially when the effect is undesirable I habitually strive to know the reason why. If to ascertain the nature of disease in the animal world be half a cure, in the vegetable kingdom it is much the same, and, alike, a remedy is of import. To succeed in securing closer observations anywhere is something gained, and this shall be my object in the following remarks.

In the vegetable world how many there are who never consider that heat is the great parent of all increase. A sufficiency of heat accompanied with bracing air secures perfected fruit buds in autumn, and without which a favourable spring may come in vain. Heat acts by degrees; and it is not an argument to the purpose, if advanced to the contrary, that we may have fruit on the north side of a tree, whilst the south side is barren, as the south side of a tree is more subject to damage from spring frosts. As evidence of the gradual action of heat we have the fruit buds on one branch following each other as to their state of perfectness, and, without anything deteriorating in the weather, afterwards we shall have some buds set their fruit and some not, some good fruit and some indifferent; but whatever the effect, all may be traceable to the perfectness or otherwise of the fruit bud.

I will now give a few facts that have come under my own notice this present season, and which I think will tend to prove the soundness of what I am advocating. My means of testing have been ample, and personally I am quite satisfied. From my own garden I took up with the utmost care a large number of fruit trees and bloomed them under the most favourable circumstances in tubs under glass. I have also grown several other trees under exactly the same circumstances, which I have had from the Messrs. Rivers of Sawbridgeworth and from Mr. Smith of Worcester; some taken from the open ground, and some which had been grown in pots. Save two Plums (a Transparent Gage and a Victoria), an Apple (Early Harvest), and one solitary fruit of *Beurré d'Amanlis* Pear, of those subject to the cold rains we had here in the north last autumn, there has been no fruit from trees taken from the open ground. From two Worcester Pearmain Apples—that gem recently introduced by Mr. Smith—I have had fruit with which I have been delighted, grown partly under glass and set out to colour and flavour in the open air. From one small tree of *Souvenir du Congrès* Pear had from Mr. Rivers I have had six fine fruit, and from another which had only two fruit buds I have just taken—rather too early—two Pears which I wished to have ripe for our local show, the one weighing 14 and the other 14½ ozs. Of Jefferson's Plum, likewise from Mr. Rivers, I have fine fruit, whilst the Plums from the trees taken from my own garden are all more or less deformed. This clearly proves that one reason for the loss of the fruit crop here has been brought about by the undeveloped fruit buds of last season.

I shall now show that our wet autumn was not the only deteriorating influence we have been subject to; spring frosts had something to do with it, and perhaps also had cold rains, but I hardly think so. Of a row of Early Harvest Apple, from whence the one I fruited under glass was taken, there has not been one fruit, neither have I a Plum outside. With a more favourable spring those fruited inside prove that we should have had some fruit, better or worse, outside. To further show that the fruit buds here were only partly developed I will

advance one more convincing proof. I had some Apples from the open ground from Mr. Smith, which I planted in the open ground, and they are now carrying fruit. This is the more convincing, considering that the removal was not an advantage. Another proof is that Court-pendu-Plat Apple, or the Wise Apple as some call it, did not bloom till spring frosts were gone, and still I have not on thirty trees one fruit. Late varieties, of course, are more especially depending on autumn heat, and thus this variety would be more readily affected by autumn cold than others. We learn from the above facts that with an exceptional spring we may do with a previous unfavourable autumn, and that with a favourable autumn, or with the greater heat of the south of England, fruit buds can battle more successfully with an unfavourable spring.

What can we do to assist Nature under such circumstances? Drainage is one valuable aid, and of which we cannot speak too highly. The tree with stagnant dampness about its roots is in much the same predicament we are in, and much the same likely to get out of order as we are likely to do when we have permanently wet feet. As one remedy we must drain where necessary. Much has been written about allowing trees to grow more naturally. I believe in copying liberally our lessons from Nature, but I believe for all that that it is man's duty to improve—"to mend Nature." For a certainty if, say, thirty-six fruit be a full crop, then twelve fruit will be fully half the weight of the thirty-six, and perhaps be of quite as much market value. Judiciously thinning a crop is one desirable way of mending Nature. I have no objection to a tree expanding, but I have a great objection to having a tree so overcrowded that the inner branches are deprived of reasonable light and air. As another aid we must thin the branches of fruit trees liberally, and if we go so far as to protect in spring, to be of more avail we must remove our protectors each morning, or, to our discomfort, we shall find that we are simply making our blossoms so much the more tender, that when frost comes they will only stand a proportionate amount.

Since the above was written I have taken first prize in the dessert class at the Bishop Auckland Show with the Worcester Pearmain Apple spoken of, also at the Alnwick Show; and with the Pears I took second prize amongst twenty-two competitors, I unfortunately having had to set up three unripe fruit.—JOSEPH WITHERSPOON, *Red Rose Vineries, Chester-le-Street.*

CREAM PINE MELON.

THE figure and description of this new Melon in Dr. Hogg's "Year Book" led me to purchase a packet of seed, for I am quite as fond of Melons as of Strawberries. The crop was a good one, and the first fruit was ripe about the middle of August. It was only of medium size, but so heavy that I was somewhat puzzled to account for its weight of some 3½ lbs.—quite half as much more as any other sort of Melon of the same size. Upon cutting it the reason was obvious by the extraordinary solidity and thickness of the scarlet flesh and the small quantity of seed enveloped in such thick pulp as left no hollow space in the fruit. The flavour is hardly rich enough for this Melon to find favour with a connoisseur, and yet it is so sweet and juicy that it is likely to become a general favourite.

It has answered very well upon a mild hotbed in an ordinary garden frame, growing so freely and cropping so well, and also requiring so little attention, that I feel disposed next season to devote two or three frames to it in order to obtain a certain quantity of a fruit that is likely to supplement the regular supply so well.—FRAGARIA.

ALNWICK HORTICULTURAL AND BOTANICAL SOCIETY.

THIS Society held their annual Show on the 5th inst. in the beautiful grounds of Alnwick Abbey, kindly granted for the occasion since the commencement of the Society by His Grace the Duke of Northumberland. A lovelier or more romantic spot could scarcely be wished for the purpose, with the beautiful Alne meandering in its tortuous course through the grounds, and the district rich in historic associations. In addition to the many attractions that Alnwick affords the Castle gardens are kindly thrown open to the public, which is an immense boon and highly appreciated, as every courtesy is shown to visitors by the Superintendent, Mr. Ingram, and his staff. His Grace takes also a very active part in the interest of the Show. He is the patron of it, gives very liberal prizes towards it, and has provided the Society

with a sinking fund, so that it is proof beyond a calamitous or indifferent day. The Society discharges a very useful work by giving prizes to the youth of the district for attainments in botany and for collections of Algae, British Ferns, &c. His Grace further gives a portion of ground to each scholar attending the dual schools, together with prizes for the best vegetables, &c., grown there.

Apart from the above special features of the Society the Show has ranked amongst the best of the northern shows for a number of years, and may be said to be a first-rate show of vegetables and cut flowers. The collections on this occasion were arranged in a circular marquee and four tents radiating from it, which were all well filled. The framework of the tents was all festooned with evergreens, and in the centre of the marquee was a choice collection of stove and greenhouse plants sent from the gardens at Alnwick Castle by Mr. Ingram.

In the class for nurserymen and gentlemen's gardeners the first prize of £4 for eighteen Dahlias, dissimilar, fell to Mr. Oliver, gardener to Lord Ravensworth, Eslington, who staged magnificent blooms and not coarse. Second went to Mr. Carrick, Saltwell; the third and fourth to Mr. Brown and Mr. Wm. Oliver respectively. These were an imposing show: there were eight stands. For the best twenty-four Hollyhocks and best twelve Hollyhocks Mr. Thompson, nurseryman, Newcastle, and Mr. Oliver were first and second respectively; the flowers were very fine but not large. The first prize of £4 for twelve Gladiolus went to Mr. Codlin, Meldon, for fine spikes, the best being Seduction, Marquis of Lothair, Seedling (very fine), Meyerbeer, and Psyche. Mr. Charlton, Morpeth, was second with seedlings of great merit and one spike of Shakespeare with eleven expanded flowers. A section was provided for amateurs and cottagers, who staged excellent examples of the above-named and other flowers. A timepiece value £5 was won by Mr. Adams, Swalwell, for a collection of well-grown greenhouse plants.

In the class open to all for the best twelve Roses shown with their foliage the first prize went to Messrs. Mack & Son, Catterick, near York, successors to the late Mr. Harrison, Darlington. They were a magnificent twelve, fresh and large, and consisted of such flowers as Alfred Colomb, Princess Beatrice, Marie Rady, Sénateur Vaisse, Louis Van Houtte, &c.

In the plant classes the Northumberland cup, value seven guineas, for best five plants, stove or greenhouse, was won by Mr. Thompson, Newcastle, with large specimens. The competition in the fruit and vegetable classes was good and the produce was generally of excellent quality; and the collections of wild flowers and fruits, bouquets, dried Ferns, &c., attracted much attention.

The Show was well managed, but it would have been much more complete and instructive had names been attached to the several specimens and products.

GOLDEN SPIRE APPLE.

FRUIT large, conical, snouted, ribbed round the apex, and of a perfect codlin shape. Skin smooth and shining, pale straw yellow where shaded, but of a thin golden colour tinged with pale orange where exposed to the sun. Eye rather deeply sunk in a ribbed and angular basin; segments divergent and pointed, sometimes quite reflexed; tube conical; stamens basal. Stalk half an inch long, slender, set in a deep and somewhat uneven cavity. Flesh tender with an agreeable acidity, and with all the merits of a fine cooking Apple. Cells open.

A fine solid-fleshed culinary Apple, which comes into use in August, and will continue till December.

This is an Apple that must make its way as one of the favourites in small gardens, and also in orchards for the supply of the markets. Its early-bearing property, its handsome appearance, and its great excellence make it a formidable rival to Lord Suffield, Manks Codlin, and all that class. The following extract from a letter received from Mr. L. Killick of Langley, Maidstone, whose opinion on such matters is worth having, will be acceptable.

"I have grown the Golden Spire but eighteen months, and it fruited this year. You will see by your figure that it is conical; and I imagine, though not so large, that it will be as good a bearer as Lord Suffield. The wood grows very upright and the shoots are small in circumference, giving an "aspeny" appearance to the tree. I should imagine it is not a very free grower, and therefore suitable for small gardens, &c."

Mr. Richard Smith of Worcester also writes: "We have grown Golden Spire Apple for twenty years, and consider it an excellent culinary Apple. I believe I met with it in Lancashire, where it is or was much cultivated. Golden Spire is a most valuable and prolific Apple, greatly superior to Keswick, and in the same way."

Our figure was taken from a specimen gathered in the garden of C. W. Hamilton, Esq., of Hamwood, Ireland, where a small tree was completely laden with fruit, all of which was as nearly as possible equal to that figured. Mr. Hamilton informed us he had received the tree from Wiltshire. We do not know the

Fig. 32.—Golden Spire Apple.

origin of Golden Spire. Mr. Killick informs us he received his trees from Mr. Richard Smith of Worcester.

VICTORIA PARK.

PERHAPS the highest eulogium that can be bestowed on Victoria Park is that it is worthy of its royal name. Certain it is that the industrial masses residing in the east end of the metropolis have at their disposal a park of rare beauty, flower beds not excelled by any in Her Majesty's own garden, and equalled by few in the gardens of the aristocracy. But it is not to the Londoners only that this park affords pleasure, for it is inspected by visitors from all parts of the country, some seeking enjoyment—an unique floral feast for their own gratification, others gathering instruction that can be turned to account in the more efficient performance of their duties. Every day during the present month gardeners desirous of making themselves acquainted with superior examples of the most artistic mode of garden embellishment will visit the London parks, and note the plants employed and their disposition, in order that they can the better produce examples in the same style in the gardens under their charge.

It is easy to denounce what is termed carpet bedding, as easy as it is to produce coarse examples of it both on paper and on grass; but the only effect of cold-shoulder criticism is, that the artistic mode of garden embellishment referred to becomes more and more popular, and examples of it increase and improve. It is noteworthy, too, that the more this mode of garden ornamentation is practised, the more popular at the same time appear to be the hardy flowers of our borders—perennials. The London parks afford good evidence of this. Last week the mixed borders in Battersea Park were alluded to as being more beautiful and more admired than ever, and the same may be said of the semi-wild borders in Victoria Park. It is also certain that the mode of filling flower beds with dwarf-growing plants remarkable for their attractive foliage and arranged in geometrical designs, has been adopted in many private gardens during the past few years, yet not for a long time past have hardy flowering plants been so greatly cherished and so much inquired for as they are now. This may suggest that carpet beds are not in themselves satisfying. Granted. They are not satisfying, neither is it desirable that they should be; yet, notwithstanding, they are capable

of affording much pleasure, as they are of displaying real skill and chaste artistic beauty, formal, perhaps even artificial, but not the less on that account, but rather the more are the beds attractive.

Possibly the extended employment of dwarf ornamental-foliaged plants has created a want of a corresponding nature—a desire for flowers. It is certain that flowerless gardens will never be popular in England, and it is a long time since flowers—sweet and beautiful old border flowers—had so many admirers as they have now. Advanced florists have little or no sympathy with artistic flower gardening, it is too artificial. Artificial! As if it were half so artificial as their own art of plucking out and arranging the petals of one flower, curling those of another, flattening those of a third, and so on. It is easy to find fault, but not easy to do so consistently.

In Victoria Park carpet bedding is extensively and skilfully conducted. The beds are models of good taste, and worthy of a journey from one side of England to the other by those who desire to see first-rate examples of this mode of decoration. Yet numerous as are the beds referred to, let the truth be told that they do not occupy a fiftieth of the space that is devoted to hardy flowering plants—mixed borders. The mile in length of borders has been crowded with flowers for months past, and they are gay now. By the law of contrast these borders show to greater advantage the lowly and artistic beds, hence the contemporaneous increase of the two modes of garden decoration alluded to.

Yet attractive as are the mixed borders it may be safely stated that ninety per cent. of visitors to the park go for the purpose of inspecting the carpet beds. These are most finished examples of their kind. Very few kinds of plants are employed in them, and more than half of them are hardy or nearly so; but the different arrangements are chaste in the extreme, still bright and cheerful. It were futile attempting a detailed description of the beds. Nearly all of them are carpeted with the now popular *Mentha*, which is in admirable condition, brightened by Golden Feather, which is employed for forming narrow wire-like boundary lines, enclosing in some cases individual plants, and in others masses of plants of neutral colours. The scroll bed in this park is unique of its kind. It is termed the jewel bed, from the delicate tracery forming the small designs of bright colours, which show to great advantage in the emerald setting. Between this bed and the broad walk runs a low Privet hedge, but so great have been the crowds of admirers that the fence has been completely trodden down, and in places wholly destroyed, and a fence of iron is now necessary to keep the crowds off the grass. Another bed upwards of 20 feet in diameter is strikingly beautiful. The raised centre is carpeted with the rich olive-green of *Herniaria glabra* dotted with Alocs. From the centre chain-like festoons of Succulents enclose masses of *Sedum glaucum*, from which rise fine plants of the distinct silvery *Chamaecephala diacantha*; and *Mentha* and accompanying nick-nacks are bounded by bright lines of *Alternanthera* and Golden Feather, the bed being edged with Succulents. Both in design and planting this bed is a masterpiece of the art that it represents. There are other, many other, beds of the same nature, but varying in pattern and detail, all of which should be seen by those desirous of obtaining hints on this increasingly popular mode of garden decoration.

It is not difficult to account for the popularity of carpet bedding, for apart from the inherent attractiveness of the beds their beauty is infinitely more lasting than that of beds of flowers. The flower garden proper in this park was grand for a few weeks, but the rains washed away its beauty; the carpet beds, on the other hand, appear to shine brighter by the drenching they received. But although these beds may be inspected with great advantage and in a measure may be imitated, still it is not to be expected that similarly highly finished examples can be produced in all private gardens where carpet bedding is desired. In the London parks the whole resources of manager and men are devoted to the keeping of the beds, but in private gardens a hundred other wants must be supplied, and the beds can only have a share of attention. That is a condition that should ever be borne in mind when the relative merits of public and private flower gardening are under consideration.

The subtropical beds are also excellent, and indeed the whole park is in the high-class condition that merited, as it received, the high approval of the Prime Minister on a recent visit of inspection. Mr. McIntyre and the skilled gardener Mr. Bullen have good cause to be satisfied with their achievements this

year; they have set themselves a great task for the future, for of course they must go on improving.—J. W.

PORTRAITS OF PLANTS AND FLOWERS.

PHILODENDRON SERPENS. *Nat. ord.*, Aroideæ. *Linn.*, Monocelia Tetrandria.—“Imported from New Grenada by Messrs. Veitch, and well suited for the wall-decoration of a humid tropical house.”—(*Bot. Mag.*, t. 6375.)

CASTILLEJA INDIVISA. *Nat. ord.*, Scrophulariaceæ. *Linn.*, Didynamia Angiospermia.—“*Castilleja indivisa* is one of the most brilliantly coloured of the genus, its bracts, which are orange-scarlet in a young state, in age become of an intense carmine red and last a very long time; they were in beauty in the beginning of May, and continued until the last week of July, in the border of the rockwork of Kew. Mr. Thompson of Ipswich, who sent the plant to Kew, observes that it seems easy to raise and to rear, that it was grown under glass, and that the colour of the bracts would deepen out of doors (which has been the case). It is a native of Texas, and described by A. Gray as a winter annual, flowering in spring without the survival of the radical leaves.”—(*Ibid.*, t. 6376.)

ALOE COOPERI. *Nat. ord.*, Liliaceæ. *Linn.*, Hexandria Monogynia.—“The present plant was discovered by Burchell in the year 1814, in the neighbourhood of Uitenhage, flowering in January and February. It was refound in 1862, by Mr. Thomas Cooper, on grassy plains in Natal, and brought by him to this country in a living state. It has been for some time at Kew, but it has not yet flowered. The drawing was made by Mr. Wilson Saunders from a plant that flowered at Reigate.”—(*Ibid.*, t. 6377.)

GILIA BRANDEGEI. *Nat. ord.*, Polemoniaceæ. *Linn.*, Pentandria Monogynia.—“It is an exceedingly rare plant, discovered by the very intelligent and energetic collector whose name it bears, on perpendicular rocks at the source of the Rio Grande, in the rocky mountains of S.W. Colorado. It was again found by Drs. Gray and Lamborn, very sparingly, on the Sierra Blanca, in Southern Colorado, in July, 1877, at an elevation of upwards of 12,000 feet. Mr. Thompson of Ipswich raised it from Colorado seed, and flowered in May of the present year.”—(*Ibid.*, t. 6378.)

HUERNIA BREVIOSTRIS. *Nat. ord.*, Asclepiadaceæ. *Linn.*, Pentandria Monogynia.—“It was discovered by Mr. Bolus on the dry rocky hills of Ryneveld's Pass, near Graaff Reinet, in South Africa, at an altitude of 2700 feet, where it is tolerably common, and flowers in April. A drawing was made from a plant sent to Kew by Mr. Bolus, which flowered in August, 1875.”—(*Ibid.*, t. 6379.)

MARICA BRACHYPUS. *Nat. ord.*, Iridaceæ. *Linn.*, Triandria Monogynia.—“Imported by Mr. Wilson Saunders from Trinidad about the year 1871, and presented by him to the Royal Gardens several years later. With us it flowers in August, and requires stove treatment.”—(*Ibid.*, t. 6380.)

ASHBURNE HOUSE,

THE RESIDENCE OF EDWARD BACKHOUSE, ESQ.

OF the many residences of the opulent situated in the environs of our great seaport towns few excel in sylvan beauty or horticultural interest the charming retreat at Ashburne. The mansion, a noble pile of stone, stands upon a gentle eminence about a mile due south of the flourishing town of Sunderland, with its wide and clean streets, noble buildings, and small but pretty and well-kept park, which, judging from the number of persons we saw there, is appreciated, and deservedly so. Ryhope Road, by which we wended our way to Ashburne, is rendered particularly pleasing by the trees that skirt and in many places overhang it. The approach to Ashburne is by a pretty lodge through the avenue of trees, which, considering the near proximity of so large a town as Sunderland, thrive remarkably well. The principal or carriage entrance is from the north side of the house, with the customary spacious breadth of gravel, ornamented by standard Rhododendrons in tubs.

Passing the gates and traversing a walk to the left 10 feet in breadth—clean, smooth, and firm, consequently comfortable, as well as pleasing to the eye from its graceful curve and grateful colour, pale yellow—we are at once struck with the beauty that meets the eye, turn what way it may. Rhododendrons do remarkably well, being the principal evergreens, there being just enough of them to heighten the effect of the deciduous

trees, which for size and health are seldom excelled in inland grounds, while at Ashburne the sea is not more than ten minutes' walk distant. Sycamores appear to do best of all, followed by Elms and Beeches, of all which there are fine specimens; Turkey Oaks likewise thrive at Ashburne.

Ascending by winding steps the south front of the mansion is reached. The supporting stone wall of the terrace is balustraded to suit the architecture of the mansion without introducing vases at the angles, which, as we usually see them filled with Geraniums and other flowering plants, are only so many blemishes, interposing as they often do between the eye and picturesque scenery. The terrace is disposed in gravel with a flower border next the house and flower beds on grass at the east end of the house. Four Agaves disposed in tubs upon the gravel break the monotony of the balustrade, and the flower border and beds form no part of the "look-out," which from the terrace is such as few town gardens (this is, strictly speaking, a town garden) afford.

The terrace border in front of the house has a ground of *Cerastium tomentosum*, in which diamond beds are formed; planted—1, yellow *Calceolaria*; 2, *Geranium* (scarlets); 3, *Viola* Perfection, and so on throughout; 4, *Arabis variegata*, with centre of *Coleus Verschaffelti*. The corner beds of the flower garden are also amongst the neatest we have seen. The borders at the west end of the mansion are effectively planted, and the centre bed (fig. 33) is the most attractive

Fig. 33.

bed of its kind we have seen this season, and is planted as follows:—1, Specimen *Echeveria retusa*; 2, *Alternanthera amara*; 3, *Sedum* acre; 4, Mrs. Pollock tricolor *Pelargonium*; 5, *Lobelia* Ebor; 6, *Pyrethrum* Golden Feather; 7, All the "bar" lines and edge *Echeveria secunda* glauca.

Leaving the terrace at the west end a flight of steps lands us in front of the conservatory, a very elegant and substantial structure 50 feet in length, 31 feet in width, and 26 feet in height, having a curvilinear roof with ample means of ventilation, altogether reflecting great credit upon the builders, Messrs. J. Boyd & Son, Paisley. The pathway up the centre, 8 feet in width, is laid with encaustic (Minton's) tiles of elaborate design, with a widened centre. In the borders are many valuable plants, *Dicksonia antarctica* with 8 feet stem and a spread of fronds of 15 feet; *Date Palm* (*Phoenix dactylifera*), 15 feet over; *Chamaerops Fortunei*, 16 feet high and 12 feet through; *C. humilis*, 12 feet in height; *Dracæna australis*, 16 feet high; *D. Veitchii*, 20 feet high, both having heads upwards of 10 feet in diameter; *Araucaria excelsa*, a perfect cone, 18 feet high and wide; *Phormium tenax variegatum*, 7 feet high and 9 feet across; *Musa ensata*, with leaves 12 feet long; in addition to many other plants of like majestic proportions, such as *Alsophila excelsa*, *Scaevola elegans*, *Phoenix sylvestris*, and a good specimen of the Traveller's Tree (*Ravenala madagascariensis*), with its fine *Musa*-like leaves, the base of their footstalk being accompanied by a sheath that contains fresh water with which travellers in the plant's habitat, Madagascar and India, quench their thirst. Permanent-flowering plants are represented by *Camellias*, and the roof is clothed with *Tacsonia insignis*, *Lapagerias*, &c.; *Heliotropes*, *Maréchal Niel* Roses, and other plants acceptable from their fragrance not being omitted, *Fuchsias* decorating the pillars.

In front of the conservatory is an herbaceous garden in the form of a circle with a border all round, the centre being dis-

posed in beds in the geometrical style, and filled with herbaceous and alpine plants from the treasures of the Messrs. Backhouse & Son, York. The outer border is replete with the taller kinds interspersed with Roses, annuals (which make a charming display), and grand masses of Pampas Grass. Among the plants in beauty at the end of July were *Campanula Hendersoni*, *Calochortus luteus* var. *oculatus*, *Ajuga reptans* variegata, *Lychnis alba plena*, *L. Viscaria*, *Enothera macrocarpa*, *Phlox frondosa*, *Polygonum Brunonis*, *Statice latifolia*, *Veronica rupestris*, *Alströmmeria aurea*, *Epimedium alpinum*, *Pulmonaria sibirica*, *Saponaria ocymoides*, *Veronica saxatilis*, *Achillea umbellata*, *Aquilegia gigantea*, *Campanula trachelium*, *Dianthus deltoideus*, *Linum narbonne*, *Oxalis Bowiciana*, *Saxifraga serrata*, and *S. serrata elegans*. *Violas* Duchess of Edinburgh (white) and Duke of Edinburgh (deep blue) were noteworthy from their purity of colour, good form, great substance, and floriferous character; a splendid pair. Too much cannot be said in eulogy of this style of ornamental gardening, unfolding as it does fresh beauty from day to day. Gardens of flowering shrubs, low shrubs, herbaceous and alpine plants interspersed with annuals and other summer decorative plants, really produce a very effective display, there being always something fresh to awaken attention and keep alive interest—ever something or other to study and admire.

An octagon summer house fitted up in a very elaborate manner, embowered by trees, stands at a little distance from the walk by which we descend from the herbaceous garden to the pleasure ground, of which a capital view is had of the trees and shrubs that deck its slopes, such as Chestnuts, Purple Beeches, standard *Rhododendrons* (which being in pots can be lifted for the conservatory during bloom), *Pinus austriaca*, *Arbor-Vitæ*, Weeping Ash, Thorns of kinds, Evergreen Oaks, *Aucubas*, &c., tastefully disposed upon the turf. At the bottom of the incline we take a turn to the left, and the beauty of the place is spread before the eye in all its loveliness. Over the fountain, throwing its silvery spray, a good view of the grounds is obtained, to which the artist has done no more than justice in the accompanying engraving. From the grounds we pass over the Rhyope road to the kitchen garden, an enclosure of four acres. To the north and west are disposed a few deciduous trees which serve the purpose of ornament and shelter, yet not materially interfering with the cropping.

In this department are the principal glass structures. They are erected about the centre of the garden, and are rather extensive. The first house entered was a vinery 30 feet by 20 feet, all the vineries being of the same width and much of the same length—lean-to's. In this house were admirable examples of Black Hamburg black as sloes, the berries large; some we measured were $3\frac{1}{2}$ inches in circumference, though the Vines were close upon twenty years under cropping, the bunches being about 2 lbs. weight. Golden Hamburg was grand, Mr. Crament, the able gardener, being very successful with this too frequently condemned Grape; the bunches are large, 5 lbs. in weight, and the berries $3\frac{1}{2}$ to $3\frac{3}{4}$ inches in circumference. Mrs. Pince is represented by bunches of about 3 lbs. weight, well coloured, and without any small berries, this favourable result being attributed to working this desirable Grape upon the Black Hamburg. Splendid fruit of Black Prince and Grizzly and White Frontignan is also noticeable both in respect of size of bunch and berry. The next house contains three-year-old Vines. Lady Downe's is in capital trim; Trebbiano is 18 inches across the shoulder and 12 inches long, weight about 8 lbs.; Black Alicante, symmetrical bunches, reversed cones, 12 inches by 12 inches, weight about $4\frac{1}{2}$ lbs.; and Gros Guillaume (Barbarossa), $16\frac{1}{2}$ inches across the shoulder and 12 inches long, about 8 lbs. In this house are some old Vines of Muscat of Alexandria lifted nineteen years ago, now carrying good crops of amber-coloured fruit; the bunches are about 3 lbs. in weight. There is also Mr. Crament's seedling Grape Ashburne Seedling, which produces a bunch after the style of Alicante, averaging from 2 to 4 lbs. in weight, but when fully ripe is of the rich golden hue of Golden Hamburg, setting very freely, its bearing properties being all that could be desired, whilst it keeps as long as Lady Downe's. We had no opportunity of testing its quality, but Mr. Crament stated that he had instructions to plant a house of it, which denotes the estimation in which it is held by those best qualified to judge.

The next house contains young Vines not in fruit, but having canes like cudgels and eyes like nuts, the joints short and the foliage ample; all the foliage, lateral or otherwise, is retained that can be fully exposed to light. It is a late house planted

with Lady Downe's, Ashburne Seedling, Gros Colman, and Gros Guillaume; in pots or tubs are Auckland Castle and Negro Largo Figs carrying a second crop of fine fruit. The next house is Lady Downe's carrying a splendid crop of very even-sized bunches and berries without a trace of scald. The last house in the range is planted with Madresfield Court in capital order without a "flaw" of any kind. Mr. Crament tells us it does best on the Black Hamburg stock, and he has good reason for that opinion. Champion Muscat is fine and exceedingly well coloured. Calabrian Raisin has bunches 15 inches by 18 inches; but Duke of Buccleuch is not held in high esteem at Ashburne. We noticed that there were no scorched leaves and no trace of insects, that fermenting material had been employed for starting the Vines in some of the houses, the borders outside were wider than usual, and though the surface showed a neat loose appearance it was only so much skim to hide the rich top-dressing beneath; very

copious supplies of water are given to the Vines, and the roots are encouraged to the surface of the borders.

Behind the vineries were 250 plants of *Azalea indica* vars. in various sizes from the bush of 2 feet in diameter up to the pyramid of 5 feet by as much through at the base, all clean and healthy and well set with buds. The plants had canvas stretched on laths to protect them from the midday sun. Hundreds of *Chrysanthemums* in 10-inch pots were trained to one stem, and very strong and healthy they looked. There was also a quantity of dwarf *Chrysanthemums* in 8-inch pots named Perpetual White; in July the plants were well set with flower buds, and they bloom profusely in September, and are then very useful. *Sedum Sieboldi* with its pink flowers is grown in quantity for conservatory decoration in late summer.

In the stove, 50 feet by 24 feet, is a number of useful decorative plants, such as *Aralia gracillima*, *Campsidium filici-*

Fig. 34.—ASHBURNE HOUSE—VIEW IN PLEASURE GROUNDS.

folium, *Maranta Marnockiana*; *Dracenas amabilis*, *Chelsoni* and *Baptisti*, *Cocos Weddelliana*, *Croton majesticus*, *C. Weissmanni*, *Pandanus Veitchii*; Palms such as *Livistonia altissima*, *Areca sapida*, *Latania borbonica*, *L. aurea*, *Dæmonorops fissus*, and many others. Specimens—*Alocasia Veitchii*, 6 feet high and 4 feet over; *A. metallica*, 4 feet through; *Cycas revoluta*, 6 feet across the fronds; *Cocos Weddelliana*, 5 feet through and 6 feet high, and many others. In fine condition are *Musa Cavendishii*, *Bambusa stricta*, *Crotons*, *Anthurium Schertzerianum*, *A. crystallinum*, *Bougainvillea glabra*, *Stephanotis floribunda* and other flowering plants; also Ferns useful for cutting from, notably *Adiantum gracillimum*, &c.

In a long border are hundreds of East Lothian Stocks, which are very fine in spike, flower, and continuance, the perfume being delicious. Winter-flowering Heaths and Epacris were in cold pits or frames, healthy plants, promising well for bloom. In a cold pit we were shown *Todea superba* in splendid condition, having a spread of fronds of 4 feet; also other "Filmies," the secret of success being to keep them cool and sprinkled overhead three or four times a day.

A low span-roofed house is devoted to *Poinsettias* on one side, and on the other were *Eucharis amazonica*, *Pancratiums*, and the ever-flowering and very sweet *Tabernaemontana coronaria plena*, *Allamanda Wardleana*, *Dipladenias Brearleyana*,

amabilis, and *splendens*, all in good condition. Another span-roofed house is devoted to Orchids, among which we noticed good examples of *Odontoglossum Bluntii*, *Cœlogyne cristata*, *Oncidium macranthum*, a variety of *Cattleyas*, *Lælias*, *Phalænopses*, *Cypripediums*, besides *Nepenthes* in all the best varieties, and a fine *Adiantum farleyense*, 4 feet through, in very good colour.

In the Peach house, 30 feet by 18 feet, was a capital crop of fruit just ripe, consisting principally of Royal George and Noblesse Peaches and Elruge Nectarine; next to which is the greenhouse of about the same size, the roof being partly covered with *Maréchal Niel* Rose, from one plant of which three hundred blooms were cut this season; and the other part of the roof is occupied with *Lapagerias rosea* and *alba*. The stages were very gay with zonal *Pelargoniums*, *Fuchsias*, *Tuberous Begonias*—what a fine show they make! and a number of other plants. Time forbade our noticing the *Cucumber* and *Melon* pits, and taking more than a cursory survey of the kitchen garden, which appeared well cropped and very neat—indeed, we saw no weeds anywhere; but there, as in the pleasure grounds, everything appeared to the best advantage from the neatness and order that prevailed. Fruit crops outdoors appeared to be thin. To Mr. Crament we would, in conclusion, tender our thanks for his courtesy, and have only

to say that his skill as a cultivator is abundantly testified by his works.—G. ABBEY.

NOTES AND GLEANINGS.

THE double Show announced to open at the CRYSTAL PALACE on the 24th inst. cannot fail forming an exhibition of great magnitude. No prizes are this year offered by the Directors for flowers, the fixture being presumably too late for insuring superior Dahlias, Asters, &c. The prizes for fruit are very good and numerous, third prizes being included, and already a considerable number of entries has been received. This being the only autumn show of fruit near London it is expected it will prove a very good one. The International Potato Society's Exhibition to be held in conjunction is sure also to be an extensive one. Prizes are provided by many trade growers and others desirous of promoting the superior culture of the newer varieties of Potatoes. The past gatherings of the Society afford a tolerably sure index that the forthcoming tournament will be worthy of extensive patronage.

— THE DUNDEE HORTICULTURAL SOCIETY'S SHOW that was held on the 5th inst. was a display of considerable magnitude, and was altogether a great success. The Exhibition was opened by the Earl of Camperdown, who, in the course of an admirable address, remarked that "At the present time, when Art is gradually taking the place of Nature, when the beautiful is gradually receding before the useful, and when toil is lord and when smoke is king, this of all times is the time when we can least afford to give up the cultivation of flowers." There was excellent competition in the plant classes, and many fine specimens were staged. The £10 prize for twelve plants was won by Mr. A. Roberts, gardener, Dornoch, Aberdeenshire; the prize of the same amount in the nurserymen's class being awarded to Messrs. John Stewart & Sons. Messrs. Laird and Sinclair, Dundee, were successful exhibitors, and an extensive and valuable collection of plants was staged by Messrs. Ireland and Thompson of Edinburgh. Fruit was generally good, Mr. McDonald, The Gardens, Kimmethies, securing first honours in the collection of eight varieties; and for four varieties of Grapes Mr. Reed, The Gardens, Rockfield, won the first position. The display of vegetables was very extensive and fine, Mr. Neil Glass, The Gardens, Carbrook, being awarded the first prize for ten varieties. An exhibition of BEES, HONEY, AND WAX was also held on a very extensive scale, and was largely patronised. The officials of the Show are to be complimented on an Exhibition that was so satisfactory and well managed.

— "W. J. M., *Clonmel*," describes the following method of PROPAGATING THE *FICUS ELASTICA* successfully practised by Mr. Lonergan at Birdhill. Take a shoot, readily obtained from an old cut-down plant, say 4 or 5 inches long; trim off the lower leaves, and if succulent a few hours on a greenhouse shelf will be an improvement. Procure a round wide-mouthed bottle, and place in it pure rain water with a few pieces of charcoal in the bottom. Properly suspend your cuttings in this, and plunge into the warm water of a tank in the stove. In the instance referred to roots were emitted in one week, and the plants were potted in a fortnight, and are now 3 feet high three months after the cuttings were inserted, and have splendid foliage.

— THE autumn Show of the HORTICULTURAL SOCIETY OF GLASGOW was held on the 4th inst. The entries numbered upwards of two hundred more than at any previous show, and the Exhibition was a very imposing one—especially in the section for plants and cut flowers. There was also an admirable display of fruit and vegetables. A. B. Stewart, Esq., the President of the Society (Mr. Todd gardener), contributed greatly to the value of the Show by the numerous and splendidly grown specimens that he exhibited. Messrs. Smith and Simons, and Mr. McKenzie also contributed valuable collections. Mr. Robertson, Helensburgh, won the chief prize for Gladioli with splendid spikes, as may be imagined when such skilled cultivators as Messrs. Galloway & Graham had to play second fiddle. Mr. McConnochie, Cameron Gardens, won Messrs. Ferguson & Forrester's prize for ten dishes of fruit; and Mr. McBean, The Gardens, Craigend, Johnstone, secured the President's prize for a collection of vegetables. The Society is now upwards of a hundred years old, and it is pleasing to observe that vigorous efforts are being made to extend its influence and to place it in a position to be increasingly useful in the important district of which it is the centre.

— IN the nurseries of Messrs. J. Laing & Co. at Forest

Hill a fine plant of *CYCAS REVOLUTA* is flowering. The pale green mop-like cluster in the centre of the plant has a singular appearance. It is more than a foot in diameter, and seeds are forming freely. The plant has a stem about 4 feet in height and nearly a foot in diameter. The new seed rooms, bulb stores, and offices of the firm, rendered necessary by the increasing business, are now completed. They are commodious, well finished, and admirably adapted for the conducting of a large business. In one of the houses is a grand display of Tuberous Begonias, and hundreds of plants are also flowering freely in the strong clay soil of the nursery.

— AT the last meeting of the SCOTTISH HORTICULTURAL ASSOCIATION Mr. A. McKinnon, Melville Castle Gardens, read an excellent paper on the culture of the Peach. He described its early history and introduction into this country and referred to the many difficulties that attended the growing of Peaches in northerly latitudes, and concluded by stating that after taking into account all the facts of Peach culture it was necessary to have a glass house heated to ensure a crop each season. An animated discussion followed the reading of the paper, some of the members contending that artificial heat was not needed in ordinary seasons to produce a crop each side, citing instances of failure and success with and without the application of artificial heat. Mr. John Davidson of Messrs. Dicksons & Co. next read a paper on the culture of fruit trees generally pursued in the nurseries. After speaking of the ignorance that generally prevailed on this subject he detailed the system of budding and grafting, mentioning the different stocks required for different trees and the adaptability of certain stocks for various soils, and urged the more general planting of fruit trees for profit. Mr. Robertson Monro made a few remarks on autumn-flowering *Chrysanthemums*, exhibiting twelve sorts at present bearing a profusion of bloom. Miss Hope, Wardie, sent some beautiful flowers of *Dianthus atro-purpureus* raised from the Chiswick strain of seed. Messrs. Downie & Laird exhibited two fine new *Phloxes* named Lady Belhaven and Mrs. Bowyer. Mr. John Brown, Dalkeith, exhibited a wonderful growth of a Rose from a cutting inserted on April 27th this year. Mr. Wm. Black exhibited a curious *Lobelia* with blue and white flowers on the same plant. Mr. McLauchlan exhibited and explained the working of one of his verge-cutters. Mr. A. McIntosh, Paxton House, received a certificate for an excellent new round Potato named Premier White of unexceptional quality.

— OUR CORRESPONDENT "A KITCHEN GARDENER," who has also the charge of a very fine flower garden, writes, "We have just been arranging how the beds and figures in our flower garden will be planted next summer. Now is the time when this can be done properly, as any imperfections in the arrangements of the colours or heights of the plants can be seen much better now than in imagination next year at bedding-out time. By arranging the flower garden the previous season the whole can be made perfect; at least we have always found it to be a most convenient plan, and advise any of your readers who have not practised it to begin at once."

— MR. ATKINSON informs us that he recently saw a handsome SPECIMEN OF *ARAUCARIA IMBRICATA* in the garden of Mr. Douston, Settlebeck, Jedburgh. It is twenty-eight to thirty years of age, and its height is 23 feet 7 inches, girth above the lawn 4 feet 10 inches, girth at 5 feet above the lawn 2 feet 9 inches, and the total diameter of the branches is 22 feet. It is a fine specimen, though not so high as some others noted in the Journal. A thrush had built her nest in it this year about 5 feet above the ground, and it was taken possession of by some small bird when she was hatching the second sitting of eggs.

WORK FOR THE WEEK.

KITCHEN GARDEN.

THE late crops of vegetables are now progressing rapidly. Weeds, too, owing to recent rains are appearing in great numbers, and are growing freely. Those that are advanced to the seeding state should be cleared off by hand before hoeing, as when the weeds are large hoeing and afterwards raking them off is an unsatisfactory mode of riddance, especially if the weather be at all showery. Hand-weeding may be tedious, yet it is not in showery weather unremunerative, as a few days at this time of year suffice to mature the seeds of such quick-growing weeds as Groundsel, and that plague on light soils Chickweed, which if allowed to ripen now cause much trouble and annoyance in future seasons. In all favourable weather ply the hoe amongst all growing crops, which is undoubtedly the best implement for

destroying weeds whilst they are in the small seedling state, but hoeing in wet weather is only so much labour lost. Potatoes are becoming diseased in some localities. Take up in favourable weather those that have the skins set, and if the haulm be infested it is better to pull up the tops and burn them before lifting the tubers, always avoiding placing large quantities of Potatoes together in a wet state. Onions which have been taken up and exposed for a time should be stored away thinly on shelves in a dry cool room, stringing the firmest bulbs so that they may be removed to cooler quarters, so as to prolong the season when the weather is becoming warmer in spring. Do not neglect the thinning of late Turnips, Winter Spinach, &c., as they require all the light and air possible to mature the growth. If any pits or frames are at liberty they may be planted with Lettuces or Endive for winter use. They will root much better and endure more wet than those lifted when of larger size and placed in frames after the weather is cold and wet. The forwardest clusters of Tomatoes as they show indications of ripening should be cut and suspended in a dry airy house. The removal of these clusters will assist the maturing of the later fruits.

French Beans.—Make a sowing in pots, placing six beans in a 9-inch, and eight in a 10-inch pot, three-quarters filling the pots with rather strong turfy loam, draining the pots sufficiently, covering the beans from half to an inch deep, placing the pots as near to the glass as possible so as to keep the plants dwarf, earthing-up after the seed leaves are fully formed. They cannot have too much light, and should have a temperature of 60° to 55° at night, 65° to 70° by day rising to 75° or 80° with sun and free ventilation. Mohawk, Osborn's Forcing, Sir Joseph Paxton, Sion House, and Fulmer's are all good forcers, but we prefer the two first named varieties.

MUSHROOM HOUSE.

We would again suggest the desirability of forming beds for the winter supply with all dispatch, and also to the collecting of material for successional beds. Particulars for preparing the material and making-up the beds are given at page 185. The best plan of collecting the material is to place a barrow under cover so that the droppings can be placed directly in it; but where this is inadmissible the opportunity of shaking over any stable litter during dry weather should not be neglected, shaking all the droppings into a heap together, not being very nice about a little straw and its particles, as they not only increase the bulk but assist in drying the droppings and to maintain the bed in a slow and regular decomposing condition. If the compost is wet it must be dried so as not to decay too speedily, but form a warm fibrous material for the spawn to run in, hence the necessity of keeping the material dry from the first.

FRUIT HOUSES.
